
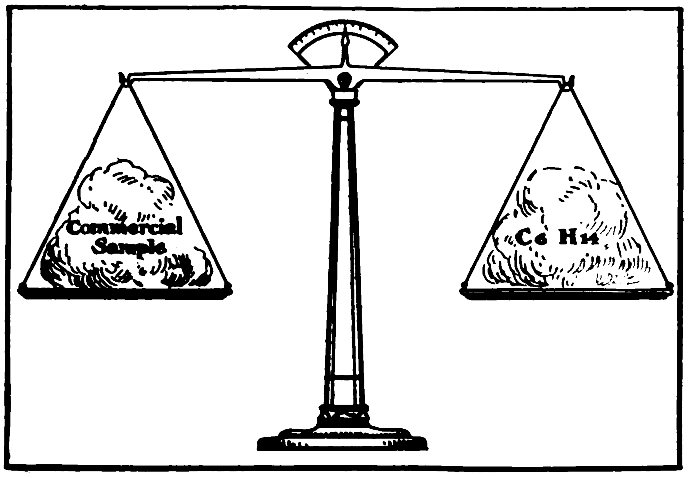

Fig. 1—Illustrating the weighing of true gasoline in comparison with automobile gasoline

When gasoline proper was being sold and used, which was several years ago, the specific gravity method of determining as to the general suitability of the fuel was satisfactory. Gasoline at that time was a close distillate lying between chymogene and benzine C. As it is at present the composition of automobile gasoline (which is not gasoline technically speaking) includes chymogene, benzine C, benzine B and benzine A, with, perhaps, a little kerosene. Hydrometers are used to determine the specific gravity of some one fluid, but it is obvious that such instruments are incapable of determining the specific gravity of an aggregation of fluids. Just to help the understanding, refer to the balance as indicated in Fig. 1; the pan at the right is filled with hexane (C_6H_{14}), which is the principal constituent of true gasoline; the pan at the left is filled with proportions of pentane, hexane, heptane and octane, with, perhaps, nonane and decane. Supposing

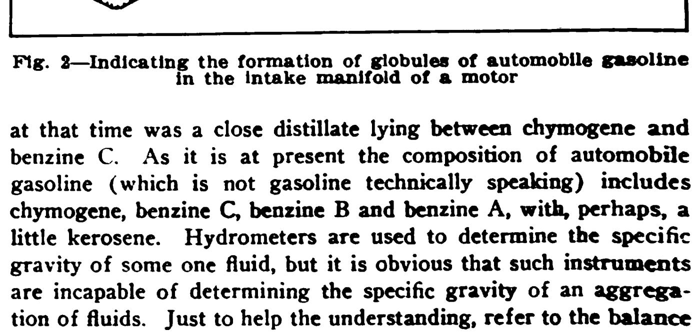

Fig. 2—Indicating the formation of globules of automobile gasoline in the intake manifold of a motor

the scales do balance, the volume of liquid may not then be the same in each of the pans, and what is equally to the point the fuel value of the two fluids would not be the same. True, the thermal value of hexane is not very different from the same value of the other constituents, but the other (less volatile) distillates would not be in such acceptable form as hexane, that is so readily burned to carbonic acid and water.

Refrigerating Effect of Gasoline Is the Cause

Editor The Automobile:

[2,348]—Why is it that the manifold on the intake side of my motor frosts up for a considerable distance from the carbureter? At times the carbureter also shows this same difficulty, if such it might be called. I will be glad to have you state in what way this frosting trouble interferes with the motor performance. Is there any way to overcome it?

Chicago, Ill. L. S. Childs.

When gasoline is changed from a liquid to a gas the volume of the gas is very much greater than the volume of the liquid for a given weight. Expansion takes place, and in expanding the gasoline gives about as much heat as is represented by the heat of compression. Ammonia, in the anhydrous state, is used for refrigerating work on account of the great change in temperature that takes place when the liquid is expanded to form ammonia gas. Gasoline is not nearly as good a refrigerating medium as ammonia, but it possesses enough of this property to do what you claim happens in your case. Remembering that the latent heat of evaporation must be overcome when gasoline is evaporated, which latent heat is equal to about the amount of heat that is required to raise 8 ounces of water 1 degree Fahrenheit, it remains to supply this heat before the liquid will evaporate. If it is not supplied at a sufficiently rapid rate the temperature will be lowered, and, as in your case, the temperature falls to that of the frosting point.

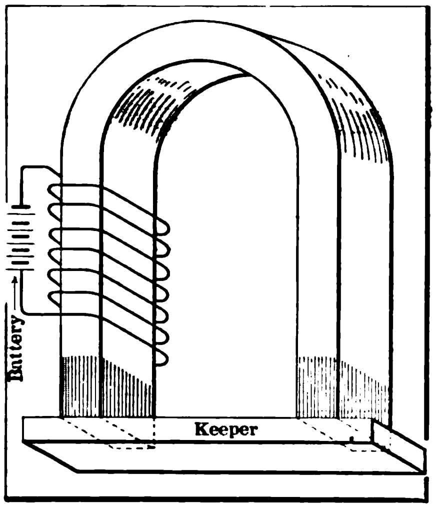

Fig. 4—Showing how permanent magnets are remagnetized

What really takes place is: Globules of liquid gasoline pass up into the manifold as shown in Fig. 2, and the heat necessary for the vaporization of these globules of liquid must pass from the manifold to the liquid; it does not transfer at a rate sufficient to satisfy the thermal conditions with the result that the temperature lowers.

One way to overcome this trouble, for such it is, is represented in Fig. 3, which is a cross-section of the float bowl of a carbureter. In this example the surfaces around the bowl are water-jacketed and it is the idea to circulate hot water in this jacket for the purpose of helping to supply the heat necessary to overcome the latent heat of evaporation of the liquid.

There are material objections to this plan; the heat should be supplied to the liquid as it oozes out of the nozzle, which is the point of vantage. The reason why it may not be the best plan to heat the liquid is that it may boil in the bowl, in which event the "steam" (vapor of gasoline) will rush out through the vent hole of the float bowl, and besides representing a considerable loss of fuel, it is likely to add to the fire hazard.

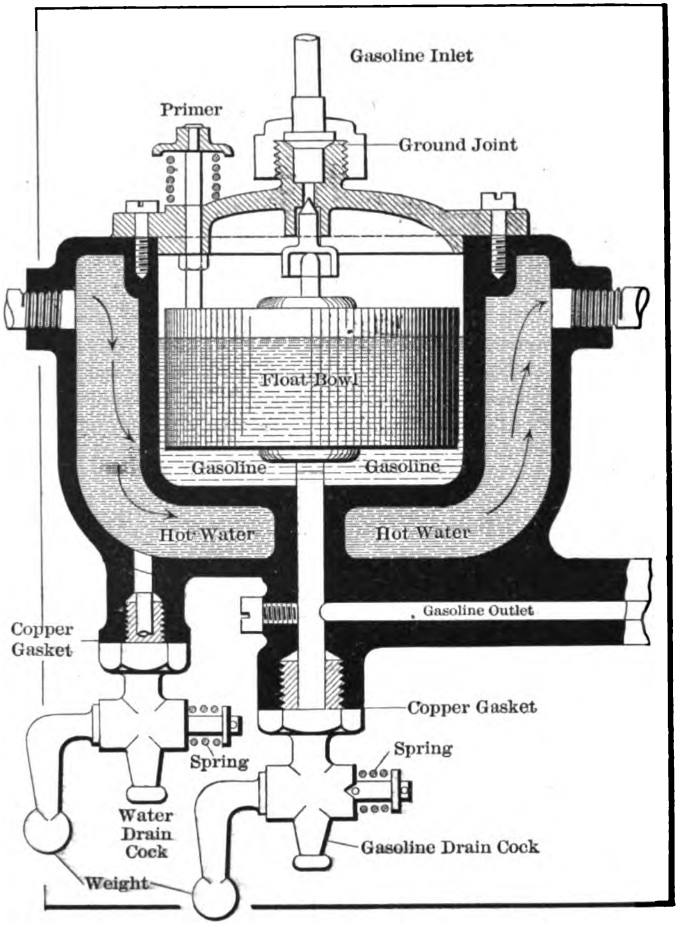

Fig. 3—Section of the float bowl of a carbureter indicating the water jacket placed for the purpose of supplying heat

The remaining two ways to supply heat to the liquid are: (a) By heating the air as it enters the depression chamber of the carbureter and (b) waterjacket the carbureter around the depression chamber; the depression chamber of a carbureter is the space in which the nozzle is housed.

Wants to Remagnetize Permanent Magnets

Editor The Automobile:

[2,349]—I am convinced that the permanent magnets of my magneto are so demagnetized that they are not now suitable for the service that I should get out of them; can you tell me how to remagnetize them? I receive so much benefit from your "Letters" that I am loath to miss a single number of The Automobile.

South Bend, Ind. G. E. Alberts.

Referring to Fig. 4 of the permanent magnets of a magneto, it shows that the magnets are separated from the other parts

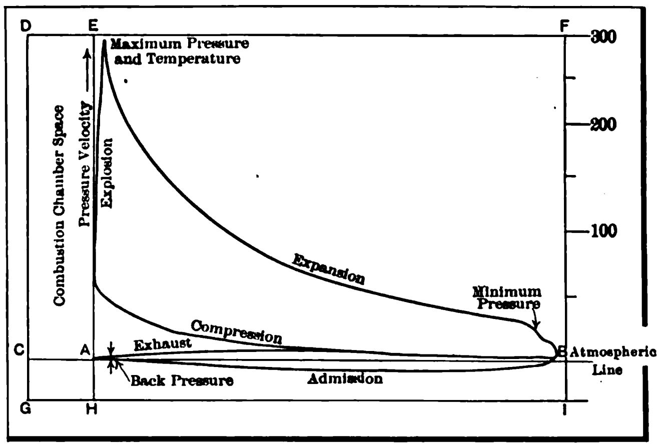

Fig. 5—Manograph card from a motor depicting the waves of pressure during the four cycles

(polar horns) of the magneto, and a few turns of insulated wire are wound around the metal above one of the extremities. A keeper of soft iron is also placed across the ends to complete the magnetic circuit. The two ends of the winding are connected to the terminals of a storage battery (the ignition battery, if it is of the storage type, will do) and the current is permitted to circulate in the windings (coil). The best way to accomplish the purpose is to allow the circuit to remain closed for, say, five minutes, regulating the flow by a variable resistance as a rheostat. In opening the circuit the current should be allowed to die out; after the operation is completed it will be proper to let the magnets rest for a few hours and then give a second dose of the charging current, repeating the performance as in the first place. If this charging process is repeated several times the magnets will become more saturated than if it is done only once, but even one charge will bring them up to probably 80 per cent. of the maximum possible charge that they are capable of holding.

Wants to Know More About Manograph Cards

Editor The Automobile:

[2,350]—A friend of mine, who seems to know quite a little about automobile motors, tells me that the manograph card is of the greatest value in determining how well a motor is performing. I am fairly well acquainted with indicator cards as they are used in steam-engine work and what I want to know is, what is the difference between a manograph card and an indicator card as it is taken on an indicator of the regular type?

Dundee, Ill. Reader.

The manograph, like the indicator, traces the pressures in the cylinder of the motor. The indicator, on account of inertia of parts, lost motion and the lack of responsiveness of the spring, fails to do accurate work when it is used in high-speed gasoline motor work, and the manograph is used in preference. The reason why the manograph is more suited to the work is due to the fact that a beam of light is utilized photographically to trace the line of pressure, thus eliminating the necessity of using a spring and a stylus or other equivalent as a pencil in a finger-like arrangement. Fig. 5 is a reproduction of a card taken by a manograph, in which the cyclic relations are clearly shown. The suction stroke is represented by the "admission" line, the compression stroke is indicated by the "compression" line, ignition takes place during the dwell of the piston at the top end of the stroke and is here represented by the "explosion" line. The power stroke is depicted by the expansion line, exhaust beginning at the point marked minimum pressure, *i. e.*, showing the terminal pressure. This card is not shown for the purpose of pointing out how good it is; indeed, it is not a good one. Were a motor to perform as depicted on this card the volumetric efficiency would be very low and the back pressure would be far too high. If the volumetric efficiency of a motor is low it is assured that the power will be below the requirement and the thermal result will be poor. In reading the cards taken by a manograph it is necessary to be fairly well acquainted with the characteristics of motors, and, while there is quite a difference between steam practice in this regard as compared with the best practice in internal-combustion motor work, the fact remains that there is a certain need for "horse sense" in both cases.

The Company Will No Doubt Make the Change

Editor The Automobile:

[2,351]—I have been a reader of The Automobile for five years and would like an answer to the following question: I have a 1907 machine equipped with make-and-break Bosch low-tension magneto. I would like to change this to the new Bosch magnetic plug, using the same Bosch low-tension magneto and distribute the spark to the magnetic plug with a timer. Could this be done with success?

Allentown, Pa. Charles W. Grammes.

Questions That Arise

CONCERNING THE LIMITED USE OF THE METRIC SYSTEM BY AMERICAN BUILDERS; EMPLOYING MAGNETOS FOR LIGHTING; PERTINENT POINTS ABOUT VALVES

[215]—What is the reason why the metric system is so little used by American builders of automobiles?

There are many reasons. To begin with, the metric system is not an American idea. This has more bearing upon the subject than might be supposed. The metric system has much in its favor, but that fact has no bearing upon the quality of automobiles, whether they be made according to English or metric measurements. If a workman is trained into thinking in English, so to speak, it is highly improbable that he can drop that habit and take up with a new one without making quite a number of mistakes. But even if he does not commit errors he will, at least, be compelled to go slow.

The potential force of habit is well recognized. If a man becomes accustomed to indulging in strong drink, or if he has a penchant for opium, it is a well-recognized fact that he is booked for life. A very few men have sufficient strength of character or bias of mind to shake off such habits and conduct themselves normally. The force of habit is just the same, whether or not the habit is that of eating opium, drinking rum, or measuring parts on a 24-inch gauge.

That the English method of measuring is thoroughly good in every practical way is shown by the excellence of the work that is done under its sway. The real English unit of measurement in the shops that are devoted to the building of automobiles is the thousandth of an inch, and fractions of this unit are taken on a decimal basis. True, there are a great number of persons who labor under the impression that a carpenter's rule is used in sizing the parts of automobiles, but they would undertake a considerable contract in telling how artisans would be enabled to locate an error of 0.0002 of an inch in the diameter of a ball, for instance, by any such method.

The great complaint that is made about the English system of measuring is that it is not provided with a scientific foundation. These critics point out that the metric system has a scientific basis for its being. Ancestry is to be lauded; practice makes perfect. In the meantime what is the significance of the respective foundations for linear measurements to the man who wields the rule? The authorized standards of the two foundations of linear measurement are as follows:

The International standard meter is derived from the Metre des Archives and its length is defined as the distance between two lines at 0 degree Centigrade.

In the English system (which is the same as the United States standard) the Troughton scale is the standard.

This information is all that the machinist would be able to procure as a practical statement of the facts, and in the long run he would be compelled to go to a maker of measuring instruments and purchase one that he would be able to use.

From the cost point of view, there are many other reasons why makers should go slow about adopting new standards of measurement. Take the centering of gears in a transmission system; if noise is to be aborted the centers between the prime and lay shafts must be true within 0.0005 inch. This accuracy is assured, not by depending upon artisans to scale closely, but by the use of gigs; is it the use of any system of measurement that governs this? No. The distance is fixed by the pair of gears used. The number and pitch of the teeth of the pair of gears disposes of this matter.

The inter-relation of the members in the make-up of the automobile are fixed independently of the system of measurement for the most part, and it is highly improbable that such matters can be readily shifted. Men must be permitted to speak the language that they understand, or they will fail to grasp the situations that confront them. There are other reasons why the metric system is not being rapidly absorbed in this country, but they have been exploited from time to time and at great length in some of the cases.

[216]—Is it not possible to employ magnetos for lighting as well as for ignition work?

Barely possible. It must be remembered, however, that the magnetic field of a system of permanent magnets is very weak as compared with the magnet field that is afforded when the magnets are of soft iron and wire-wound. The electromotive force generated by an armature rotating in a magnetic field is determined as follows:

$$\text{Va} = \frac{\text{Ia} \times \text{sa} \times \Phi}{10^8} = \text{electromotive force impressed on the armature windings.}$$

$$\text{Ia} = \frac{10^8 \times \text{Va}}{\text{sa} \times \Phi} = \text{number of the inductors wound on the armature.}$$

$$\Phi = \frac{10^8 \times \text{Va}}{\text{sa} \times \text{Ia}} = \text{total flux of the magnetic force emanating from one pole of the magnet.}$$

$$\text{sa} = \frac{10^8 \times \text{Va}}{\text{Ia} \times \Phi} = \text{speed of the armature in revolutions per second.}$$

It will be seen that the voltage depends upon the total flux emanating from one pole, all other things fixed, and this property of permanent magnets is relatively very low. It is, of course, possible to increase the speed to a certain extent, but even this choice is limited, partly on account of possible mechanical trouble. and to quite some extent on account of heat losses; they increase materially with speed due to hysteresis and Focault currents, quite apart from bearing trouble and the effects of centrifugal force.

[217]—Is it not possible to increase the diameter of the rotor and in this way add to the ability of the magneto to deliver enough current to supply the lamps as well as the ignition system?

No. Increasing the diameter of the armature does not add to the ability of the permanent magnets. The peripheral velocity of the armature can not be increased beyond a certain point in any case, and this velocity can be obtained with a small diameter rotor running at a high rotative speed just as well as it can with a large diameter rotor, which would have to be run at a lower rotative speed.

[218]—Would it not be possible to add to the number of turns of wire on the rotor and in this way make up for the lack of strength of the permanent magnets?

No. The internal losses would increase so much as to reduce the output of the armature to a point too low to serve for the stated purpose. The question of commercial efficiency, so called, is not a point worthy of serious consideration, it being the case that the total power required is so low as not to introduce a serious loss. The point is that the armature would have an internal loss so great, in proportion to the output, that it would probably be destroyed by heat.

[219]—What is the lift of valves in well-made motors?

About 8 millimeters.

[220]—Is it good practice to make the lift of both inlet and exhaust valves the same?

Very likely.

[221]—Do some designers make a distinction between inlet and exhaust valves in this regard?

Yes. The Mercedes, in one type of motor, established a lift of 8 mm. for exhaust and 7 1-2 mm. for inlet valves.

[222]—What is the most prolific cause of knocking in a motor, assuming that the bearings are properly taken up and the mechanism proper is in reasonably good working order?

Every other knock would have to be of a thermic character. If it may be assumed that there is not a growth of carbon it still remains to observe if there is a projecting fin or a pocket of some character in which carbon may settle and insulate the metal from the cooling influence of the water in the jacket.

Columbia Is Ready

MARK 85 IS THE LATEST FROM THIS PLANT; VESTIBULE TYPE OF BODY IS A DISTINGUISHING FEATURE; ALL MODELS REFINED AND AMPLIFIED

IN connection with the announcement of its 1911 models it is interesting to note that the Columbia Motor Car Company has incorporated therein not a few refinements and several novel features, as has been its custom in each of the sixteen years it has been engaged in the building of automobiles. For the coming season two gasoline cars are announced. The well-known Mark 48, which first saw the light in 1905, is continued, with some refinements and a few changes, but will be known as "Mark 48, Lot 5." In addition, there will be a new model, denominated as "Mark 85." It is with the latter that this article will more particularly deal.

Among the body designs offered in the Mark 85 are four- and six-passenger vestibuled roadsters, seven-passenger vestibuled touring car, limousine and landaulet bodies. The four-passenger roadster bodies practically follow the 1910 lines, with the fore-door feature that has emphasized the company's body designs for the past two years. The season's novelty along these lines, however, is the six-passenger vestibuled roadster—an original straight-line body, somewhat resembling the four-passenger vestibuled roadster, but longer, and provided with two extra seats. These seats may be removed, making a very attractive four-passenger roadster with added carrying space.

The seven-passenger touring body is also enclosed with vestibule door. The location of the doors and gear-shifting and brake levers does not necessitate an awkward leg movement in the operation of the foot pedals. The interior of all touring bodies has been taken advantage of to supply all seating and touring comforts. The door panels are fitted upon their inner faces with deep leather pockets, with small but secure locks.

One of the most appreciated features of the Mark 85 is the enclosure of the running-board brackets. Instead of having the sheet-metal work follow the conformation of step irons, this work extends outward from the top of the frame section to a point directly over the inner edge of the running board, which it drops to meet. Into this housing is built the tool box, and behind it is placed the Prest-o-Lite tank for the headlights, and auxiliary ignition battery, etc., thus giving the running board an absolutely clean and light appearance, and preserving the long lines of the car.

All bodies are of metal, reinforced with wood, and all open

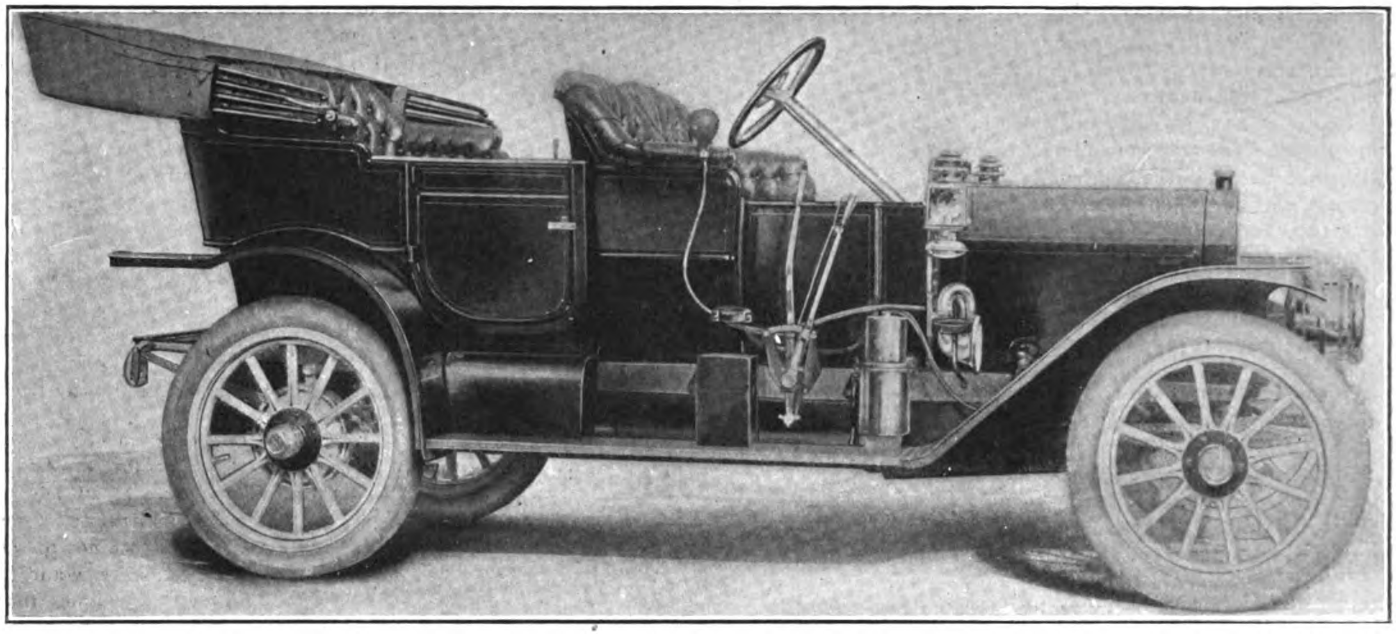

Fig. 1—Vestibule type of body that distinguishes the Columbia automobiles for 1911

bodies are trimmed with the best quality of hand-buffed leather with curled hair and coil spring upholstery, there being a wide choice allowed purchasers in upholstering and trimming of coach bodies. The front seats are individual. Mark 85 open bodies carry four, six or seven passengers, all the closed bodies being designed to carry seven. In Mark 48 the passenger capacity of closed-body designs is four, five and seven; closed bodies, five.

The motor of Mark 85 develops 35 horsepower, A. L. A. M. rating, that of Mark 48 being rated at 32.4. The former's wheelbase is 120 inches, as against 115 inches in the older model—the tread in all instances being 56 inches, with a road clearance of 11 inches.

Wood artillery wheels with forged-steel hubs feature all this year's models, demountable quick-detachable rims being included in Mark 85, and Universal quick-detachable in Mark 48. All brakes act on rear wheel drums, foot brakes being of the contracting, band type and the emergency of internal-expanding shoe type.

Four- and six-passenger open cars of the Mark 85 model are equipped with 36 x 4 tires, front and rear; seven-passenger open and closed cars, 36 x 4½ front and rear. Quick-detachable clincher tires are standard on all Mark 48 cars—four- and five-passenger, 34 x 4 front and rear; seven-passenger and closed bodies, 34 x 4 front, and 34 x 4½ rear are the standard tire dimensions.

There is a wide option in Mark 85 color schemes. In open cars: green body, gray gear; blue body, gray gear; green body, green gear; blue body, blue gear; Wedgwood green body and gear. Limousines and landaulets: green, blue or maroon. In Mark 48, Columbia blue body and cream gear or Columbia green body and cream gear are optional.

* Vestibul

Principal Mechanical Features of the Mark 85

The motor is of the four-cylinder "T-head" type, with cylinders cast in pairs, having a bore of 4⅞ inches and stroke 5½ inches. The water jackets are cast integral with the cylinders. The valves are of large diameter, the intake and exhaust valves being on opposite sides of the motor, with large water circulation areas around the valve seats and valve stems. The design of the cylinders includes a polished plate top, which may be removed for inspection.

The ignition is the new Bosch double system, using eight plugs. There is an independent battery system and an independent magneto system. One or the other, or both systems in common may be used. In no way is this to be confounded with the previous Bosch dual system with two sources of supply and a single scheme of distribution. The new Bosch double system includes two absolutely independent sources of current and means of distribution.

The two systems are controlled from a single switch mounted upon the dash, which switch is operated by hand or foot, and a rotating barrel with stops for battery or magneto contacts or at a midway stop when all eight plugs are used in firing. The switch handle is fitted with a locking device and the switch cannot be removed from the "off" position without the key is properly inserted in the switch handle. This feature will make

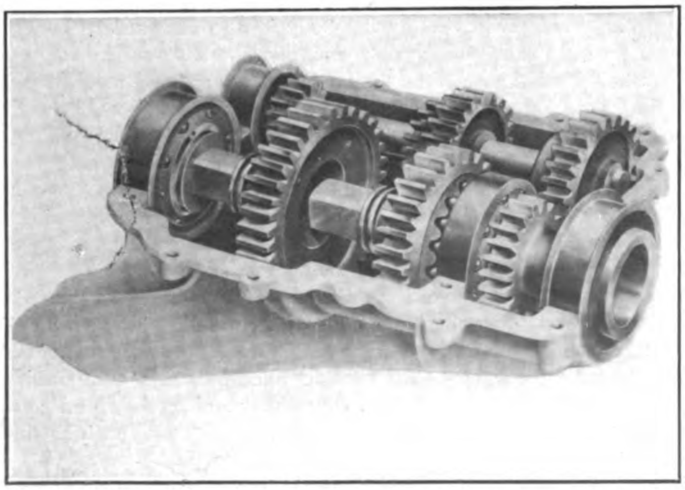

Fig. 2—Transmission gear of the Mark 85 car, showing short shafts, Hess-Bright ball bearings, and using fine materials

the tampering with or unwarranted use of cars difficult of accomplishing if not absolutely impossible.

The crankshaft is of generous proportions, with large bearings and webs, and the connecting rods are drop forged. The engine bearings are of special-alloy white metal. The motor is suspended through four hollow square legs and through which extend standpipes, gauze covered, to provide for crankcase ventilation.

The lubrication plan includes a powerful gear pump of 15 pounds pressure capacity. This pump circulates oil from a reservoir in the crank case through a conduit cast within the middle section of the motor and from which there are diverse pipe leads to all bearings. The system includes a sight-feed indicator, located upon the dash, that the circulation of oil may be noted at all times. The front timing gears are included in the lubricating system, and there is poured from the top continually upon the engaging surfaces of these timing gears a powerful stream of oil. This oil, in falling, is strained and returned to the reservoir to be again forced through the main and secondary leads. This is a lubricating method used in previous Columbias, and in some few other high-powered cars.

Radiation and cooling are insured by a powerful centrifugal pump keeping water in continuous circulation. A modish cooler of ample size and fine design with high peak, behind which is located a belt-driven, ball-bearing and eccentrically mounted fan, cools the circulating water. The water connections are of spun brass and of graduated diameter to allow for even distribution.

The clutch is of the cone type. The facing, however, is a commercial packing, a product obtainable anywhere, and being an admixture of asbestos and other elements. This provides a clutch capable of finding and maintaining its own seat, and further, it is impossible to burn out. The clutching action, too, is arrived at through a powerful leverage, so that the clutch is easy of operation. The pedals are adjustable, suitable for any leg length, and are of the disappearing type, leaving a clear floor board.

Roadster

The transmission is similar to those used in Columbia cars since 1903. In this transmission there is a very short length of shaft left unsupported. Both the main and secondary shafts are equipped with Hess-Bright ball bearings. Operation is through a selective grid iron gate by a single lever within the driver's easy reach.

The rear axle is of the full-floating type, with side torsion rods. The torsional strains of the axle are taken by the torsional bars, and there is no interference with the free action of the spring. The driving pinion is mounted within a cage upon short series Timken roller bearings, and is bodily removable, while the bevel gear is mounted directly to the differental housing, making a unit with this mechanism.

The live axles are of large diameter and extend through the wheel hubs and may be removed without raising the road wheels from the ground. The drive is accomplished through dove-tail hub flanges.

The frame is of pressed steel with a drop at the rear allowing for practically a straight-line drive, and the propeller shaft is

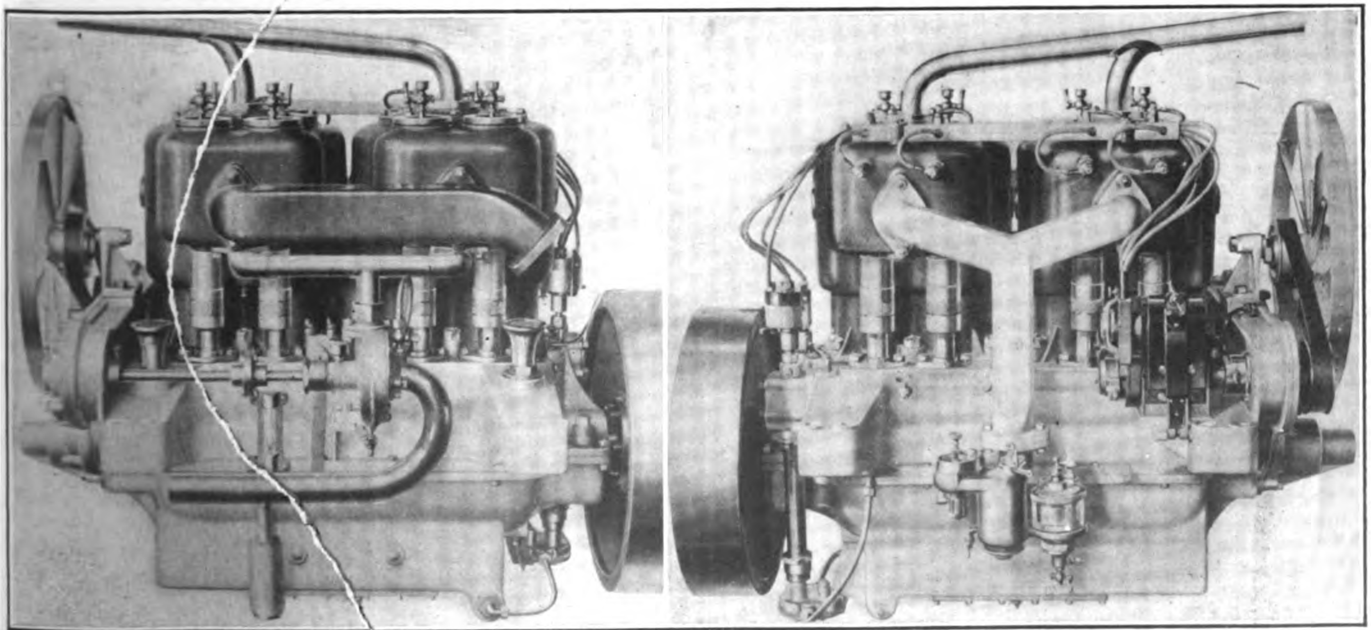

Fig. 4—Two views of the Mark 85 Columbia motor, showing the magneto and carburetor on the right-hand side and the water pump on the left

mounted in encased universal joints of ample capacity for the load, and which joints are subjected to practically no wear. Both front and rear springs are generous in number of leaves, and are of semi-elliptical type. These springs have been especially designed and selected for their resiliency and capability of accepting both light and heavy loads, thus adjusting themselves to all carried weights. The wheel hubs are drop forged and the front axle is a solid forging of I-beam type, and with integral spring seats. The steering gear is of the worm and sector type and irreversible, and is contained within an aluminum housing which is mounted directly upon the top of the side frame member.

The trimming of Mark 85 touring car and roadster is of hand-buffed black leather, while the limousine and landaulet are of green, blue or maroon broadcloth or leather. Mark 48 trimming is uniformly of hand-buffed black leather.

The equipment of Mark 85 cars is most complete. A spare carrying rim is included, so that tire changes may be easily made. The spare tire irons are fitted into the frame brackets and the fenders, which are new and without visor caps, and are strongly supported with dove-tail irons. Proper suspension and protection for springs is safeguarded with the inclusion of a full set of four shock absorbers. Bosch high-tension magneto and Exide storage sparking battery of six volts capacity are standard equipment, as is a Prest-o-Lite tank. There are two large and powerful gas headlights, and three oil-burning lamps on this car.

The side oil lights are mounted upon brackets forged integral with the dash irons, and the headlights are stayed against the possibility of vibration. The taillight is mounted out of the path of dust and where the lightrays fall directly upon the registration number. The solidly anchored trunk rack is large enough to accommodate large touring trunks. Foot-rest, robe rail and horn, are within easy reach of passengers and driver. A full complement of usual and special tools is contained within a leather-bound canvas roll, with leather strap and tie buckle. Beneath the rear seat is placed a tray so proportioned as to accommodate the top side curtains without breaking the celluloid windows. Muffler cut-out, operated with heel press, and connected with bell cranks and rods, is supplied with all cars, as is a storage locker of large carrying capacity. A plunger pump self-contained hand oiler of large capacity is located beneath the motor bonnet, and is spring held against the chance of falling.

The Columbia price proposition is sufficiently varied to appeal to all classes of buyers: Mark 85, four-passenger roadster, $3,300; six-passenger roadster, $3,400; seven-passenger touring, $3,500; seven-passenger limousine, $4,800; seven-passenger landaulet, $4,900. Mark 48, Lot 5, five-passenger touring, $2,750; four-passenger roadster (vestibuled body), $2,750.

New Continental Rim

NEW IDEA IN DEMOUNTABLE RIMS; A PLURALITY OF BAYONET JOINTS ARE TAKEN ADVANTAGE OF IN FASTENING THE TWO MEMBERS OF THE RIM; LIGHT CONSTRUCTION AND EASE OF OPERATION ARE DOMINANT FEATURES

EXPERIENCE teaches that road wheels are subjected to more abuse than any other part of an automobile, and the cost of road-wheel upkeep is higher than the cost of gasoline or even the wages of the chauffeur. This being so, it becomes necessary to examine into this situation at frequent intervals with the hope, perchance, that some way will be found for reducing the largest factor that influences for a high up-keep. Many autoists find that it is one thing to save up enough extra money to purchase an automobile, but if the car is kept in constant service after it is received the cost of road-wheel upkeep assumes proportions that merit attention. This is not a matter that should be complained of on the assumption that the cost is out of all bounds; the point is that the largest item is the one that should be worked upon with the expectation of reducing it if possible.

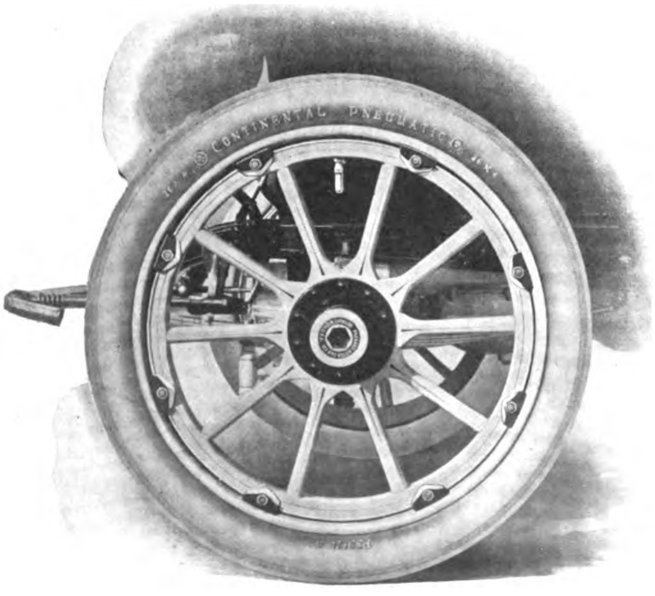

Fig. 1—Showing the work completed—ready to proceed

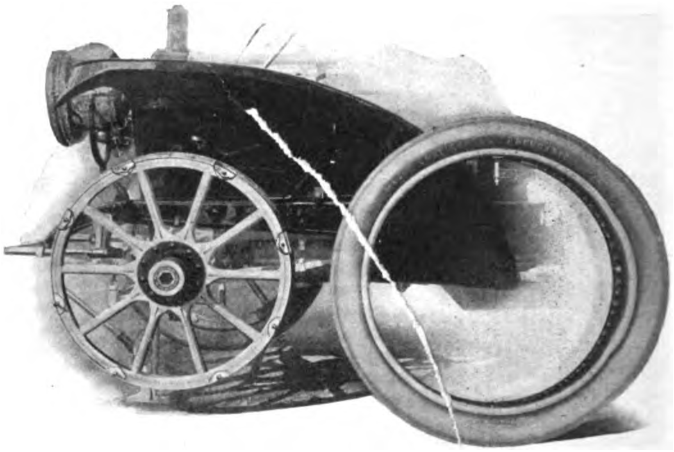

Fig. 2—The stripped wheel, with rim and tire ready for adjustment

This question of road-wheel upkeep has several angles; it is well understood, or it should be, at any rate, that tires will last over twice as long if they are removed and repaired promptly than they will if the little wounds are allowed to fester.

But the removal of tires is an undertaking that the average autoist does not take kindly to—the work is too hard. Under the circumstances the greatest stride in the direction of a low cost of upkeep is to provide rims that will save labor and coax the owner of the car to examine the tires at frequent intervals.

That tire-makers appreciate this phase of the situation must be manifest if account is taken of the strenuous efforts they are continually making to improve rims, it being the idea to so facilitate the work that tires may be removed and replaced with but slight effort, not only upon the road when a puncture has to be coped with, but in the garage, with a view to reducing tire depreciation by the only known way, *i. e.,* keeping the wounds healed up so that mildew will not creep in and pursue its ravenous course.

The latest effort along advanced lines is being made by the Continental Caoutchouc Company, New York City. The new rim is here illustrated in various ways with a view to clearly depicting the plan of design, general construction and the proper method of use.

How the Rim is Made and Used

The character of the material used in the new Continental rim is of such high grade that it responds to the dies so readily as to make it possible to form a series of "bayonet" joints between the two members, as shown in Fig. 3. By this arrangement the two parts are joined or disjointed readily, and the security offered by this form of joint is adequate for the most exacting need in this service. When the parts are slipped into place, as a further inducement for security, a locking mechanism is set With a view to showing how the locking is done reference may be had to Fig. 5, of the operation of placing the outer rim, and to Fig. 6, depicting the locking operation; this is also the position that the tire is placed in when it is desired to unlock the rim prior to removing the tire.

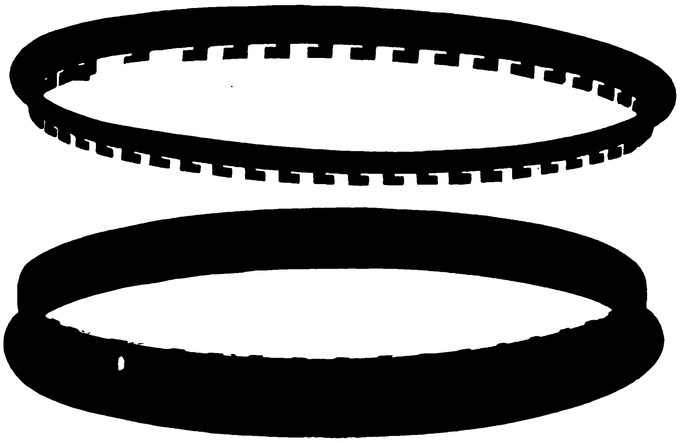

Fig. 3—Showing the rim and the series of bayonet joints between the two members

The wheel, with the new rim removed, is presented in Fig. 2, and the rim with the tire in place is stood up just in front of the stripped wheel. When the tire is placed in the rim the complete unit is slipped into place over the security rim on the felloe of the wheel, and when all is properly adjusted the locking operation is done in the manner as indicated in Fig. 4. The finished undertaking is pictured in Fig. 1.

The new product is known as the Gilbert type of "Detachable Demountable" rims, and among the points of advantage are numbered the fastening devices, utilizing the principle of the wedge, there being six fasteners, with specially contrived locking nuts, the latter being so designed that they cannot be detached from the wedge; hence the autoist, in making a repair on the road at night when it is dark, is not likely to have to make a fruitless search for missing nuts.

The method of securing the wedges is so nicely contrived that there is no tendency of the rim to "freeze," which is a character of trouble that has proved the undoing of many of the earlier efforts in this direction.

One other matter that has been cared for in this rim lies in the design, which is so contrived that the bolts are not subjected to bending moments; this is extremely important, it being true that the bolts would scarcely hold out against the force of continued service were they so placed that they would have to take the work as cantilevers.

In the matter of weight the design lends facility, and the material reduction in weight that the company has been enabled to make in this, over all its previous efforts, is to be commended.

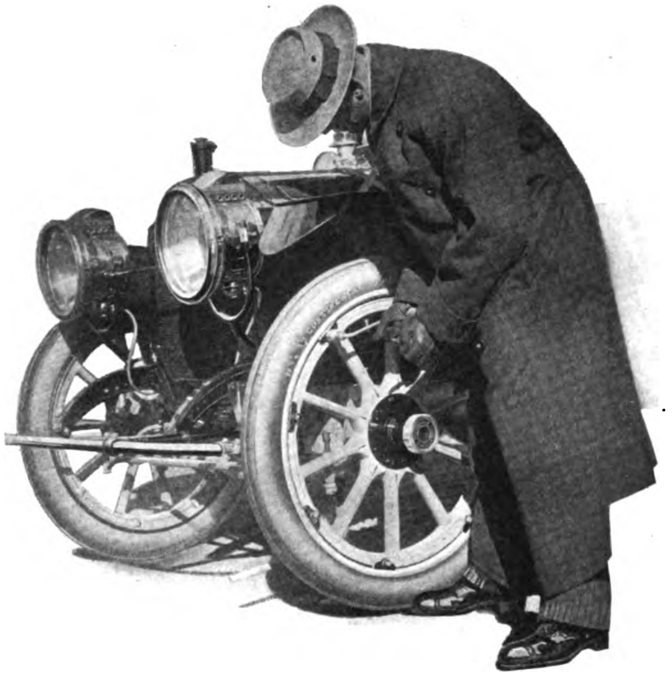

Fig. 4—The final operation—locking the attaching device

The bayonet joint method of securing the two numbers of the rim is responsible for this particular improvement, due to the fact that strength is imparted by utilizing many such joints rather than to have accumulations of metal at a few points around the periphery. The rims are formed in dies, avoiding the necessity of making the mass of material enough for the purpose of joining parts, or affording thicknesses of sections such as could be recommended in work that has to be riveted.

The lowered weight counts for economy of operation in that the flywheel effect is reduced to a low ebb; difficulty in steering will therefore be less, and the wear on tires, due to gyroscopic action, will fall to the low limit. It is, of course, difficult to appreciate that flywheel effect is a factor in this work, but those who know the good qualities of a large mass in the flywheel of the motor will most readily understand that it is a real force; if this actual force is so placed that it can do damage instead of good it stands to reason that the less of it there is, the better.

The idea of having an inflated tire along is catered to in this example, and since the tire may be mounted on an extra rim ready for instant use the amount of trouble the autoist will be put to on the road is minimized. Then, too, tires depreciate unless they are properly stored. With a tire mounted on a rim and somewhat inflated, provided it is covered to keep out light and dust, it is in a position of vantage.

The rim will take either clincher, quick detachable or Dunlop style tires. One of the parts of the rim comprises one clincher and substantially the whole of the base; the other the second clincher. The former is provided with a series of rectangular projections on the under side of the base all around the edge; the latter, with mating members, engage with the projections on the former. When the two parts are put together the extending feet first

Fig. 5—Putting the outer rim in place

Fig. 6—Locking (or unlocking) the rim

pass between the projections, and by means of a special tool one part is then rotated slightly with respect to the other so as to cause the projections and the mates to interlock. The two parts are securely held in this position by a hinged spring pressed key or lock fitting between one pair of the horizontal locking devices. The device is readily unlocked.

The tool furnished with the rim consists of a base plate which is slotted to pass over the square part through which the valve stem passes. The sides of the extension and of the slot are inclined so the tool can be passed over, only from the side, and not from the top. To this base plate is pivoted a lever arm which, when the base is slipped in place, engages behind one of the extensions and a twist on the lever arm then shifts the loose clincher until the bayonet joints are firmly interlocked. When a tire is to be placed on the rim, the sequence of operations is as follows: The tire is first placed on the wider part of the rim lying on the floor, and in case quick detachable tires are used, care must be taken to see that the tube is properly placed under the flap; then the smaller part of the rim is placed in position, care being taken that the flap does not prevent it from seating properly. The tool is then placed in position and the lever is drawn to the right to close the rim. When Dunlop tires are used on these rims, rubber bead fillers must be placed in each clinch of the rim. The regular flaps are used in the case of both types of clincher covers, and valve spreaders on tubes with all types of quick detachable tires. The operations in removing the tire from the rim are the reverse of those necessary in applying.

Digest

EXTRACTS ON TECHNICAL LINES FROM 50 BEST FOREIGN PAPERS—EXAMPLES SHOWING INFLUENCE OF WEIGHT AND GEAR RATIO ON CONVENIENCE IN OPERATION—VALUE OF TWO DIRECT DRIVES

The travelling qualities which will be produced by fitting a certain body to a certain chassis, or by selecting a transmission gear with three gear speeds instead of four, or with a new ratio between the different gear speeds instead of one which has already been tried, may be more economically figured out in advance than it may be ascertained by trials at the factory or by purchasers of the vehicle in practice. And the same applies to the number of seats with which the automobile is provided and the load with which it; therefore, may be expected to be operated in daily use. The various resistances which a motor must overcome are: (1) the rolling friction, which may be taken as equaling about 13 kilos per ton (28 3-5 pounds per 2204 pounds) on good, hard roads; (2) the resistance to penetration of the atmosphere, which is about 6.5 grammes per square meter of front projection of the vehicle for a forward speed of one kilometer per hour (author says 1 meter per second, but this is a slip) and growing with the square of the speed. On hills there should be added to this about 10 kilos per ton (22.04 pounds per 2204 pounds) multiplied by the percentage figure of the incline. If the vehicle weighs 1 ton this makes a resistance of 50 kilos on a 5 per cent. hill. Assuming that a vehicle weighing 1,000 kilos and with a front-projected area of 1 square meter travels 84 kilometers on a level road, the power developed by its motor may be calculated approximately by means of those figures. The road resistance is 13 kilos; the air resistance is 84 squared multiplied by 6.5 grammes, which equals 45.85 kilos and makes the total resistance 58.85 kilos. This is overcome at the rate of 84 kilometers per hour, or 23.3 meters per second, and 58.85 kilos multiplied by 23.3 meters per second makes 1,373 kilogramme-meter-seconds, which equals 18.3 horsepower, since 1 horsepower equals 75 kilogramme-meter-seconds. The horsepower at the wheel rim must, therefore, be more than 18 horsepower. If the vehicle is supposed to be in direct drive with an efficiency of transmission of 72 per cent. at the wheel rim, the motor must then develop 25.4 horsepower.

If the vehicle weighed 2 tons instead of one, a 30-horsepower motor would be necessary in order to reach the same speed on a level road; or, with the same motor of 25.4 horsepower, the 2-ton vehicle could reach a speed of 71 kilometers per hour, a speed reduction of 15 per cent. due to increase of weight. If, instead of increasing the weight, we increase only the front-projected area, as by attaching a wind shield, making the area 2 square meters instead of 1, the vehicle can only reach 68 kilometers per hour, meaning a speed reduction of 19 per cent.

Let us now compare the running of two vehicles, one weighing 1,000 kilos with a projected area of 1 square meter, the body being, for example, that of a runabout or a torpedo shape, the other a limousine with 2-square meter resistance-area. Both are supposed to have a motor of a maximum power of 28 effective horsepower at 1,200 r.p.m., and an efficiency at the wheel rim of 72 per cent. so that the power at the rim will be about 20 horsepower for each vehicle. The transmission ratio is supposed to be such that the light vehicle A will make 84 kilometers per hour on direct drive when the motor turns at 1,200 r.p.m., and the second vehicle B will make 66 kilometers per hour at the same motor speed.

A 3-per cent. hill is encountered. Vehicle A could scale it at 73 kilometers per hour, and vehicle B at 48 kilometers, if it were possible to maintain the motor speed at 1,200 r.p.m. But the connection between the motor and the wheels is supposed to be rigid. At 73 kilometers the motor vehicle A will give only 19.6 horsepower, and at 48 kilometers the motor of vehicle B will give only about 16 horsepower. The speed of these two vehicles will, therefore, go on diminishing on this hill of 3 per cent. until a state of equilibrium is reached—that is, until the resistances are equalled by the power available at the wheel rim. And this state of equilibrium is sure to be reached, because the power of the motor diminishes less rapidly than the resistances. Everything lies in knowing whether the equilibrium will be reached before the motor gets down to its lowest number of revolutions, say 400. It will, in fact. A calculation which is elementary, though somewhat lengthy, since it implies the solution of equations of the third degree, shows that equilibrium is reached at 70 kilometers per hour for vehicle A, the motor turning at 1,000 r.p.m. and developing 19 horsepower, and at 40 kilometers for vehicle B, the motor at 580 r.p.m. and developing 13.5 horsepower. In scaling the 3 per cent. hill, on the direct drive, vehicle A thus loses 15 per cent. of its speed, while B loses 26 per cent. What is the maximum gradient which these two vehicles can climb without changing gear? This must be the gradient which they can climb at 400 r.p.m. when the motor develops 9 horsepower at the rim, (If this statement seems doubtful, it measures at least the best which the very competent author can say on the subject; he evidently takes 400 r.p.m. as the minimum admissible for calculations.) Vehicle A will then run at 28 kilometers per hour and will scale a gradient of about 7 per cent., while vehicle B will run at 22 kilometers per hour and will not climb a grade of more than 3.9 per cent. Similarly, a 5 per cent. hill may be scaled by vehicle A without change of gear at 58 kilometers per hour, with the motor producing about 17.5 horsepower. Vehicle B, on the other hand, will have to change gear, in which case two possibilities of construction are at hand. Either there is only one direct drive and the next gear below implies gearing down in the transmission box; or the transmission box has two direct drives, the speed next to the highest being also direct. Let us take, for example, a box with four speeds, of which one is direct, and the four gears in the following ratios: first to second as 0.46 to 1; second to third as 0.65 to 1; third to fourth as 0.77 to 1. This gives for vehicle B at 1,200 r.p.m. 66 kilometers per hour on fourth speed, 50 kilometers on third, 32 on second speed and 14 on low.

With this box, vehicle B will not be able to mount the 5 per cent. hill; neither on the fourth speed, as just referred to, nor even on the third speed. The efficiency of the transmission, which was 72 per cent. on direct drive, has, indeed, fallen to 50 per cent. by the gear reduction and the maximum power available at the rim will be 14 horsepower instead of 20—a loss of 6 horsepower due to the intervening reduction gear. Equilibrium would not result until near the vehicle speed of 12 kilometers per hour, at which the motor would turn at 250 r.p.m., which has been supposed to be impossible, the minimum assumed being 400. It must then be necessary to take the second speed, which will permit vehicle B to ascend the grade at 28 kilometers per hour with the motor developing 18.3 horsepower. The influence of the carriage body makes itself strongly felt. If it was not noticeable on the level road and was not enormous on a 3 per cent. hill, it becomes preponderant on a 5 per cent. hill. Vehicle A takes this on the direct drive and vehicle B cannot even take it on the third speed. No speed lever is touched on vehicle A, while the lever is manipulated four times on vehicle B.

The transmission with two direct drives gives different results. —By C. Faroux in *La Vie Automobile,* to be concluded.

Ability to vary the compression of a motor at will and the value of provisions aimed at he establishment of this feature in motor operation, are discussed. Actually one contracts or enlarges the admission port in order to slow up or accelerate a motor. This method of regulation has an inconvenience, because in throttling the admission, one reduces the compression. And ignition of the mixture which, thanks to the carbureter, remains of about the same composition becomes precarious below a certain pressure, the safe limit being about 2 kilos per square centimeter. If the compression could be maintained constant, such as by varying the volume of the compression chamber or of the stroke, extraordinary reductions of motor speed would become practicable, especially with ignition from a storage battery and coil. A vehicle could then be run through the streets of Paris on the high gear at the speed of a man's walk. Moreover, the fuel consumption per horsepower hour would be no greater for operation under the throttle than for full power, and this would be of the highest economical importance for the traffic in big cities, the same object being sought in taxicabs by using motors of small power. Outside of the cities it would become practicable to travel over level ground with low compression and poor mixtures and to increase the richness of the mixture where more power was required. Such a motor would consume little fuel on level roads, because it would be possible to adjust the compression and the mixture most suitably to one another for each motor speed. Whether these advantages would compensate for the complication involved in securing them is mainly a question of adroit construction.—*La Vie Automobile,* August 6.

To clean a honeycomb radiator of sediment the following method is recommended in preference to the use of a jet of steam. Prepare a 10 per cent. solution of potash. Heat it. When the boiling point is just reached, pour it into the radiator after closing the pipes which in service lead to and from the motor. Stir every hour for twelve hours by turning the radiator upside down. Pour the solution out by way of the same opening at which it was poured in. Screw a hose with water under pressure into the opening at the opposite end and run a stream through for a few minutes.—*La Pratique Automobile,* July 25.

Carbureters vs. Steam Boilers

DISCUSSING RELATIONS OF CARBURETERS TO INTERNAL COMBUSTION MOTORS; HOW THEY TAKE THE PLACE OF STEAM BOILERS

WHILE improvements have been made in automobile motors proper to a large extent, the fact remains that the thermal side of the situation has been a laggard more or less, partly on account of the question of ignition, and largely in view of the ever-changing gasoline problem, demanding always better carbureters; that is to say, devices that are capable of interpreting the thermal value of relatively non-volatile hydrocarbon fuel. In the early days it was easy enough to design a carbureter to handle the regular grade of "true" gasoline, the reason being that it was so volatile it would evaporate with great rapidity. As the demand grew more pressing it became necessary to add the more heavy distillates in greater or less proportion, and carbureter problems advanced to the first rank.

In the meantime the patrons of the industry found out by experience that the difference between a well-performing motor and a poor one was largely a matter of carburetion, remembering, of course, that the inter-relating problem involved the several questions of ignition. This version of the value of equipment influenced the situation until some of the carbureters that were utilized on motors from abroad were large and complicated devices; so pretentious, in fine, that they partook of the dignity of units rather than holding the less conspicuous position of accessories to the motors.

Considering that a carbureter must serve in precisely the same capacity as a steam boiler does in a steam power plant, it is not far astray to regard the carbureter in the light of an important unit rather than as a mere accessory.

In a steam plant the boiler is fed with water and by means of heat the water is turned into steam; the carbureter is fed with gasoline instead of steam, and the function of the carbureter is to turn the gasoline into vapor. Both steam and vapor of gasoline hold identical positions in a general way, considering the matter broadly (there are some differences), it being the case that steam is the vapor of water and vaporized gasoline

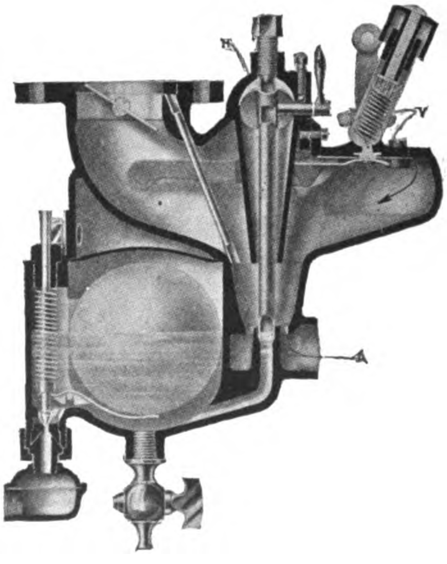

Fig. 1—Section showing functional relations

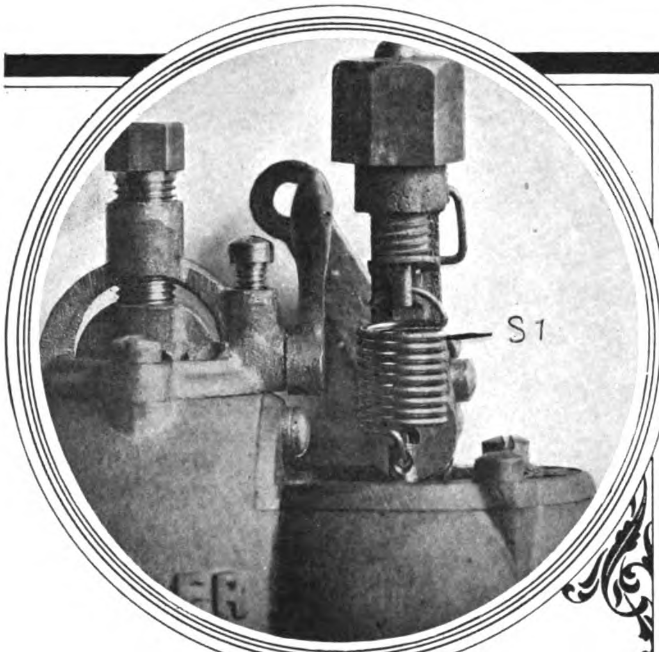

Fig. 2—Adjustment of the auxiliary air mechanism in the position of slow running passing least amount of air

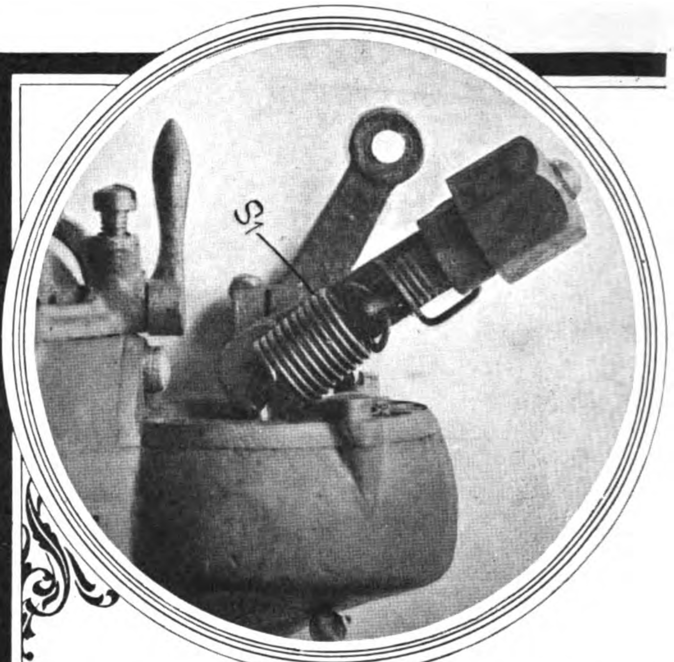

Fig. 3—Adjustment of auxiliary air mechanism in the position of fast running, requiring the maximum volume of air

represents the equivalent. All compounds, as water, steel, copper, gasoline, carbonic acid, sulphur dioxide, anhydrous ammonia, etc., are supposed to reside in one of three states—*i. e.,* as solids, liquids, or in the gas state; these are called the three states of aggregation.

A carbureter must perform the service which is necessary when a liquid is changed from its then state of aggregation to the gas state, and it is just as necessary for the carbureter to boil the gasoline as it is for the steam boiler before mentioned to boil water in order to generate the steam that makes a steam engine interpret the heat units that are represented in it and furnish energy in acceptable form to the steam engine.

The fact is too frequently lost sight of that the gasoline that is fed to a carbureter must be boiled; the heat must be supplied to the carbureter for this purpose, and the nozzle of the carbureter becomes the equivalent of the "grates" in a steam boiler. Fortunately, it is not necessary to build a fire under a good carbureter, but the fact remains that a carbureter, to work properly, must be provided with a system of "grates" that will serve for its intended purpose; otherwise the liquid gasoline will be sucked up into the combustion chamber of the motor's cylinders, where it will provide but poorly, for then it will be necessary for the motor to perform the functions of the carbureter as well as to furnish power. Motors seem to be capable of doing this to some extent, but the service that can be realized from such a busy motor is far below that which is to be expected from a motor that is permitted to do what it is designed for, and not be compelled to work as a boiler.

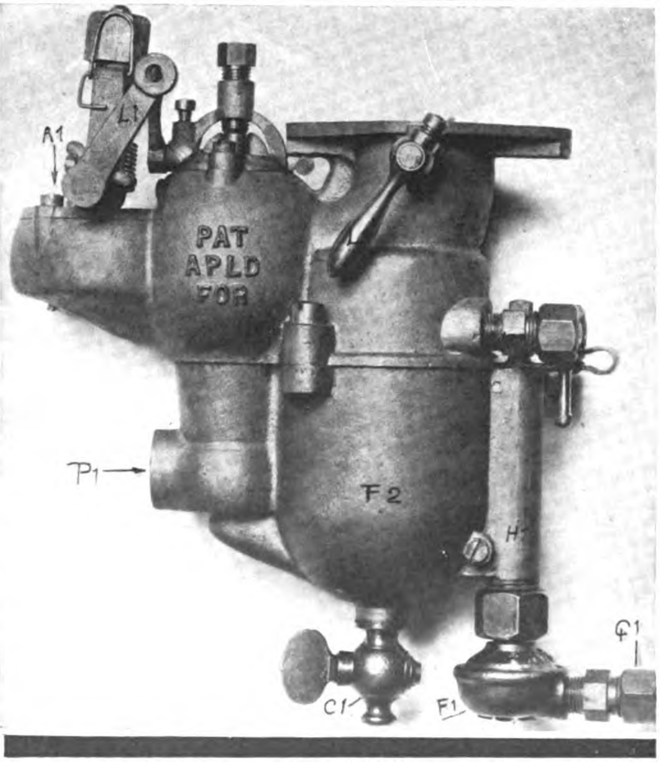

Fig. 4—Depicting the carbureter looking at the side showing the lever control for auxiliary air valve

The reason why a carbureter does not have to be provided with a hot fire under it is due to the low boiling point of the liquid used in it (gasoline); moreover, the gasoline has a lower latent heat of evaporation than this property in water, which is also a favorable circumstance.

Viewing the carbureter in the light of a supplier of vapor makes it a substantial substitute of a steam boiler. Remembering that it is not necessary to furnish heat at a temperature so high as to demand a fire, it remains to point out that there are differences in point of detail that must be given the care that they deserve in view of the importance of the undertaking. In a steam boiler atmospheric air is supplied to the burning fuel in the grate; when the fuel burns the heat from the flame is absorbed by the water in the boiler and the water is turned into steam; that is to say, the energy of the coal is delivered into the water, and when it goes into the cylinder of the steam engine it is absorbed by the piston, which in turn delivers it to the reciprocating parts, thence to the crankshaft, and on through the flywheel to the mechanism to be driven.

In the internal combustion type of motor, instead of delivering the air to the fuel and using it outside of the motor for the purpose of abstracting the heat from the fuel, the fuel is boiled in the carbureter at the low temperature that obtains in the absence of fire, and as the thus vaporized fuel is sucked into the combustion chamber of the motor it is mixed with the air so that upon arrival in the combustion chamber of the cylinder it is ready to be set on fire and burned. In this way the combustion chamber of the cylinder of the motor becomes a fire-box; the

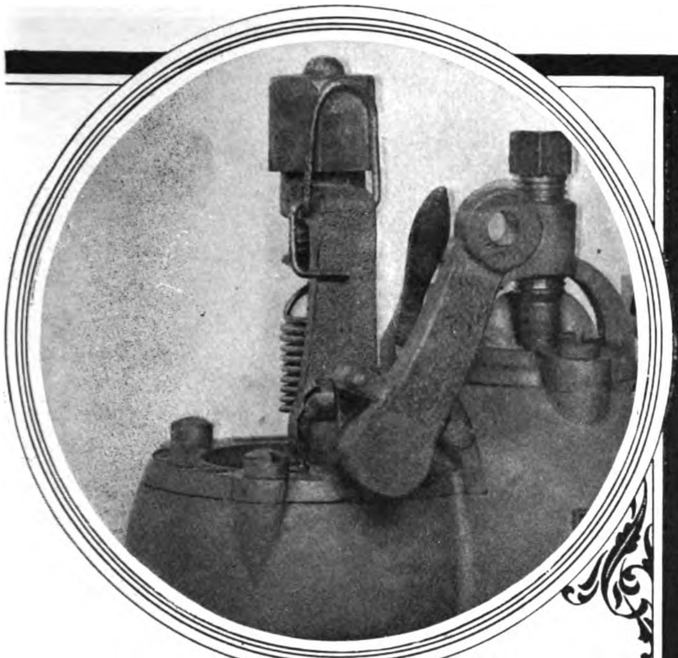

Fig. 5—Presenting the mechanism for the auxiliary air control and the lever placed to actuate the same

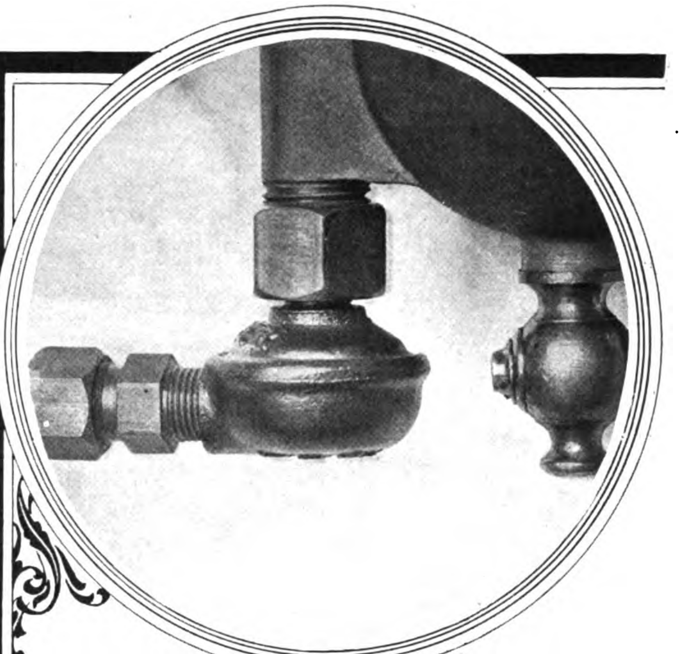

Fig. 6—Point of entrance of the gasoline to the carbureter, showing the filtering device and pipe connections

heat of the fuel is transferred to the piston just as it is absorbed from steam, and the translation from this point on is precisely as in a steam engine.

The difficulties of carburetion are many, and if account is taken of the fact that there is barely 2 per cent. of liquid gasoline in the mixture that is burned in the combustion chamber of the cylinders of the motor it will be seen that it is quite a job to properly regulate the flow of fuel with a view to obtaining the best result. This trouble would be comparatively simple were it possible to run the motor at a constant speed, and maintain **nearly a constant load as well. In automobile work neither of these conditions can be maintained, and in order to meet the varying conditions, and cope successfully with the natural troubles, it is necessary to provide a carbureter that has a separate means capable of performing each of the functions, not only separately, but in an inter-related sense as well.**

The conditions that have to be satisfied are:

(A) The carbureter must be capable of supplying a rich mixture in order to be able to readily start the motor.

(B) The carbureter must be capable of delivering the required amount of fuel (mixture) to the motor without serving in the capacity of an obstruction to the filling of the cylinders.

(C) The mixture must be varied as to quantity at will.

(D) The richness of the mixture must be a controllable factor; if a rich mixture is required it should be rendered available; if a lean mixture is indicated by the conditions the means should be afforded to readily and precisely obtain the same.

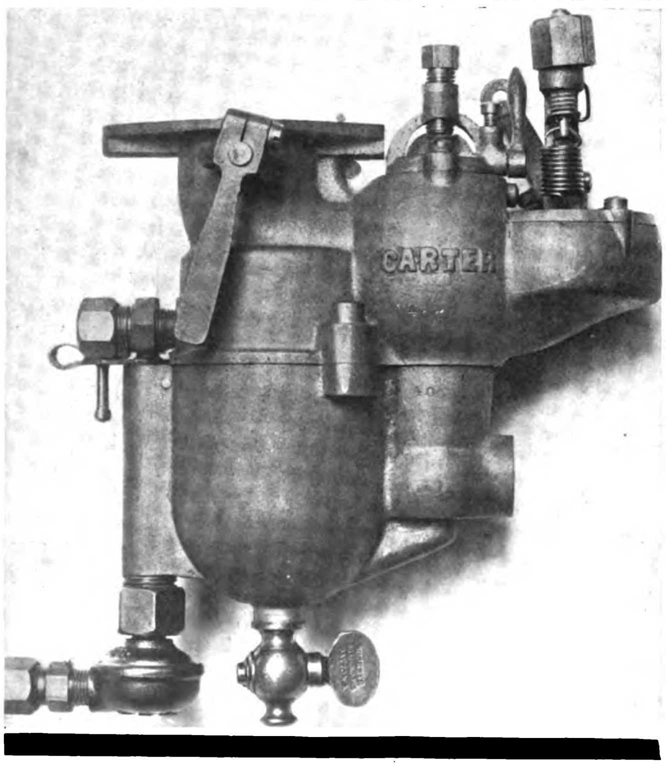

Fig. 7—Other side of the carbureter presenting the remaining lever positions; attention is called to the cock at the bottom for draining out residuum

(E) The carbureter should be so designed that it will work automatically within certain limits.

(F) The driver of the car should have at his disposal the means for relieving the automatic feature of its responsibility under certain conditions.

The Carter carbureter, made by the Carter Carbureter Company, St. Louis, Mo., will serve for the time being as an illustration of the points to be here made. In the illustration, Fig. 4 is an exterior view at one side and Fig. 7 an exterior view of the other. Referring to Fig. 4, the gasoline enters at G1, passes into the **filter F1, thence up in the needle-valve tube H1, and, under control of the needle, into the float bowl F2. As the occasion demands, the residuum, and water, if any accumulates, are drained out through the cock C1. Primary air enters at P1, and the auxiliary air passage is at A1, the control of which is brought about by manipulating the lever L. The mixture, as it passes to the intake, and on to the combustion chamber of the motor, may be throttled by working the lever L2.**

In starting the motor it is not necessary to resort to priming for the reason that an anti-strangle tube is placed (see O, Fig. 1) in such a way that, when the butterfly throttle-valve, which is under the control of the lever L2, is in the closed position, the mixture must pass to the motor through the anti-strangle tube, and the tube being small in area the mixture is relatively rich. If the mixture is too rich all that has to be done is to open the butterfly valve a little and more air will then pass up with the rich mixture; starting, under these conditions, is assured.

To obtain a better view of the situation it will be necessary to study Fig. 1 and become familiar with the parts and their relations. Referring to this illustration, it will be found that there are three methods of supplying air to the carbureter—(a) through A, which leads to the depression chamber; (b) the auxiliary air passageway V, and (c) the high-speed air inlet H. This illustration also shows the construction in general, and among the points of unusual design that are to be noted is the spherical float in the bowl. This float rests on a flattened lever and is free to revolve, but it is so housed in that it cannot depart from its rest. The flattened lever is fulcrumed at a point near the other extremity, and the needle valve is manipulated through the raising and lowering of the float, which in turn is caused by the changing level of the gasoline, due to the use of fuel by the motor. The general operation of the float bowl and the method of control of the gasoline is not different from the usual run of carbureter float systems.

In the manipulation of this carbureter the air opening for high speed is regulated once for all, and there being no regulation for the initial opening there is nothing further to do than to regulate the auxiliary air. It is in this particular part of the carbureter that novelty resides, beyond the fact that the nozzle differs in marked degree from the conventional form of nozzle.

Referring to the auxiliary air valve, the method of control is by means of a lever that is usually placed upon the dash of the car within reach of the driver. The lever connects with the motion as shown in Fig. 5. Referring to Fig. 2, the motion is in the vertical position, which is the one that permits the spring S1 to pull the strongest so that the valve is held to its seat and the air that is used up by the carbureter is mostly supplied through the primary intake at the bottom.

When the demand for air increases, the suction will also be on an increasing basis and the spring S1 is elongated; but if the driver desires to admit more air through the auxiliary intake all that he has to do is to pull the lever on the dash in such a way as to tilt the spring S1, as shown in Fig. 3. This operation has the virtue of lowering the tension of the spring S1 and the auxiliary inlet valve will then open more easily, the suction of the motor furnishing the force.

Don't

ANOTHER INSTALLMENT OF SHORT-METER ADVICE TO THE TYRO—AND THE EXPERT—THE FOLLOWING OF WHICH MAY SAVE THE MOTORIST HEAPS OF TROUBLE, PERHAPS SOME MONEY, AND PROBABLY A LAWSUIT OR TWO

Don't overlook the characteristics of ball bearings; they are made of hard dense steel in order to induce a high polish; it is this high polish that renders them fit; acid in the grease will etch the surfaces, thus destroying the high polish, hence ruining the bearings.

Don't think that the steering gear is everlasting merely because it is housed in; look over it, flush it out, put in a new supply of good lubricant; eliminate the lost motion.

Don't neglect to determine the cause of loss of compression; a lazy motor is not to be regarded as a joy forever.

Don't think that the timer is so made that you will never have to look at it; disregard of its construction will result in leaving you in the lurch some day—it may be several miles from the bark of a dog.

Don't go by a school-house like a whirlwind; how would you like to have your own children placed at the tender mercy of a lunatic with an automobile for a weapon?

Don't dispute the right of way with a fire engine; besides being a formidable rival it may be on its way to put out a fire at your house or place of business.

Don't tell "fish stories" about the speed you make on the highway; people become prejudiced when they hear them. The teller of such stories, if it is the truth, admits that he is a lawbreaker.

Don't stop at every road-side "resort"; the scenery is more attractive just as Nature made it; an automobile is an economic contrivance of value just in proportion as it does good to humanity; it is not in a good service standing in front of a "resort."

Don't go too far in any one day; there is another day coming.

Don't drive at night if the lighting equipment on your car is out of order.

Don't try out your new 50,000-candle power headlight on the public, in town; go out in the country and compete with fireflies.

Don't invite strange children to ride in your car; it gives them bad habits; you may be misunderstood.

Don't entertain the notion that dust is healthy for others; if your curiosity is excited try some of it yourself.

Don't argue with yourself about the difference between right and wrong; you know the difference without being convinced anew.

Don't overlook the fact that a four-cycle motor is, in reality, a four-stroke cycle motor. In other words, there are four operations necessary to the completion of the cycle, *i. e.*, suction, compression, expansion and exhaust.

Don't forget that it takes two revolutions of the crankshaft to deliver four strokes.

Don't count ignition as one of the operations in the four-stroke cycle motor—ignition is but an incident in counting the operations that make up the cycle.

Don't imagine that the differential gear that is placed in the live rear axle can be done away with advantageously; it is put there to weigh out the torquing moment to the two traction wheels, permitting each to go at its natural speed—one of the wheels must go faster than the other in rounding a curve unless one of the tires slips.

Don't add all the complications that the world affords to your automobile; get everything that will be of value; eliminate everything that can be of no adequate service.

Don't go on a tour with a large number of poor tools; take along a few good ones.

Don't forget that you ought to pay for a chicken if you kill it; don't kill the fowl if it can be avoided.

Don't invite your friends for a drive and then begin to show off. Remember, their necks may be worth something even if you do not place a value upon your own.

Don't forget that it is the polish on the balls of a ball-bearing that is of the greatest value from the point of view of long life and efficient service.

Don't think that balls made of inferior material will take a high polish; it may look high to the naked eye, but a microscope will disclose the fallacy.

Don't imagine that sand in the housing of the ball bearings will have any different effect than the same sand would have were it placed in your eye instead; it makes the balls blink.

Don't expect good service from ball bearings if they are placed in a gear-box and the chips from the gears are allowed to mingle with the balls; the way to keep out of the trouble that will follow is to keep the gear-box cleaned out.

Don't fail to take into account the ruinous effect of oil on the tires, but if the tires will rot out if they are steeped in oil how about the high-tension wiring around the motor? It, too, has rubber for insulation.

To Keep a Car Looking New

M. C. HILLICK GIVES A FEW HINTS AS TO HOW TO PRESERVE THE FINISH OF THE AUTOMOBILE

PRESERVATION of the automobile finish is quite as important as developing and rounding out the finish, although the former is, as a rule, quite out of the hands of the painter. Having made the painting and finishing as fine and rich and reliable as it is possible for skill and expert trade knowledge to do, the painter can thereafter serve only in the capacity of an adviser. It is fair and reasonable to say that at the present time plenty of automobile surfaces suffer abuse and go to premature decay through a lack of knowledge on the part of owners and chauffeurs of the particular sort of treatment which such surfaces need.

The highly finished surface, with its outer coat of great brilliancy, is more sensitive than any other material applied to the automobile. It requires, therefore, a care and treatment proportioned to its delicacy.

To know the best means of preservation it is essential first to understand at least in a general way some of the main causes for the decay and premature collapse of the finished surface.

Cracking of the varnish may, of course, be due to two causes: Old age, at which stage of life all varnish is destined to check and fissure and eventually lose its capacity for preserving and beautifying the surface. Premature cracking due to hurried methods of painting and finishing, by which method one coat of paint, or color, or even varnish, is applied over a coat of material not thoroughly dry. This soft, porous, and undried coat generates a gas when confined under another coat, with the result that the gas forces an outlet by cracking the surface. The cure for this latter form of surface disruption is chiefly within the hands and under the control of the painter. The fissuring of the surface incident to old age, on the contrary, depends upon the care and preserving processes practiced by the automobile users, chauffeurs, and so on. The life and usefulness of varnish can be greatly prolonged by proper care and treatment such as for example, frequent washing of the varnished surface with clean, cold water. Water cleanses and cools the varnish, strengthens it, and, in its early days of wear upon the surface, increases its brilliancy and enriches its appearance. Do not wash the surface in the sun nor permit it to dry in the sun. Neither wash it in a freezing atmosphere. During cold weather wash it no less often than during the summer months, but provide a warm apartment for such work.

Spotting of varnish—depriving the surface in spots of its lustre—is a bad form of surface blemish which the automobile owner and user who admires the beauty and brilliancy of his machine needs to guard against. Spotting generally occurs during the early life of varnish—before it becomes old, and harsh, and brittle, and devoid of elasticity. It is due chiefly to the accumulations of mud drying upon the surface and thus through the power of capillary attraction extracting the oil from the varnish. This action in many cases not only extracts the oil but the gum constituent as well. City mud, and of course, the mud of lime districts, the former being strongly charged with ammonia, are notoriously destructive to varnish lustre. The automobile driven in the mud of either city streets or country roads should upon return to the garage be washed immediately thereby eliminating the actively destructive medium.

Soapy water, or dirty water, in fact, is a form of spotting which sometimes occurs in garages and repositories, and which is very difficult of effacement. It very often happens when this soapy or dirty water is permitted to dry upon the surface it leaves a disfigurement impossible to remove except the surface be rubbed with water and pulverized pumice stone and water and revarnished. The lesson is, therefore, to avoid splashing unclean water on the surface, and never to wash the automobile with anything but absolutely clean water.

Coal gas and the gas which sometimes percolates through heating pipes will cause, if not at once, certainly in time, a very bad form of spotting. This form of spotting may be recognized by the dull, lustreless spots, showing a film of greasiness, which afflicts the surface. Damp, ill-ventilated garages cause a great deal of varnish and surface spotting difficult, and often impossible, to rid the surface of. Frequent washing and sun baths assist to both prevent and cure the evil. This treatment failing, nothing remains but to rub the surface down and revarnish.

Pure, fresh air brought into the storage quarters of the automobile in a quantity sufficient to counteract the accumulating foul air, fetid odors and gases, will prevent the varnish spotting and loss of lustre here referred to. It is a feature of economy which the garage manager and automobile owner should alike be vitally interested in.

Complaint on the part of owners and users of automobiles painted in dark colors is widespread concerning the greening and discoloration of the varnish, thus destroying to a greater or less extent the natural attractiveness of the colors and combinations of colors employed. This is due, for the most part, to the too close confinement of the automobile in an insufficiently lighted room. A lack of light affects the varnish disastrously, and in greening and discoloring it the color over which it is used is likewise injured, if not rendered of no effect outright. This emphasizes the need of a great amount of light—really the more the better—for the garage in order to preserve the original and native quality of the finish.

Practical Lubrication

THE IMPORTANCE OF PROFUSE BUT WELL-REGULATED LUBRICATION IS BEING CARED FOR IN THE RIGHT WAY BY UP-TO-DATE MAKERS

DEPRECIATION is what the owner must guard against, and there is no better way to do so than to watch the lubrication. In service, it is the duty of the owner of a car to purchase and use good lubricating oil, but it will not be possible for him to do so unless the maker provides a place to put the oil and a means for its definite circulation. That the makers of automobiles are aware of this fact is shown by the care used in designing the motors, transmissions and other units with adequate provision for the storing and circulation of lubricating oil. There are several ideas in vogue and it will be profitable for the autoist who wants to limit depreciation to study the various methods and familiarize himself with their advantages.

As a positive means of lubrication with absolutely no danger of flooding the Marmon design is offered. Fig. 1 depicts the

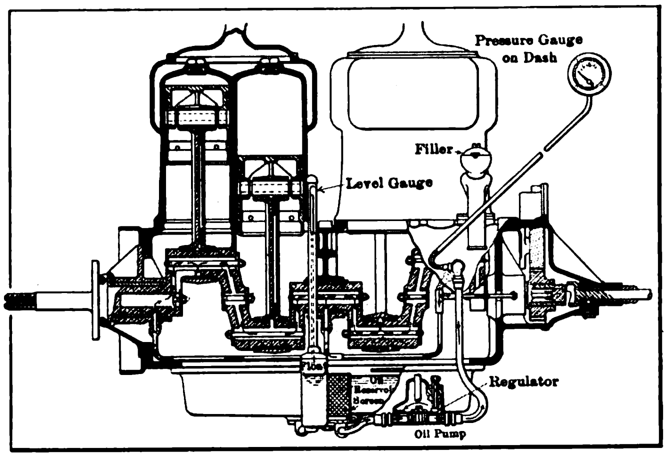

Fig. 1—Marmon lubricating system as adapted for 1911 motors of this make

1911 motor in part section, with an oil tank formed in the front end of the bottom half of the crankcase and a gear pump placed therein to circulate the oil. The direction of circulation is shown by arrows and the pressure generated on the oil is indicated by a gauge which is located in sight of the driver. In order to be able to tell if the supply of lubricating oil is adequate a float is placed in a well in the tank, from which a telltale is operated, by means of which the driver may determine the condition of the oil supply. The crankshaft is bored out to form oil-ways through which the oil flows under pressure to the main and crankpin bearings, and by a system of ducts the lubricant is also forced up to the wrist-pins so that they too are lubricated by oil under pressure. All excesses are returned to the well, but the oil is filtered on the way, and the economy of the system is decidedly pronounced, without running into the danger of using "stale" oil. The mere fact that a little oil is put into the tank daily is sufficient to guard against having it wear out, but it must be remembered that lubricating oil does wear out just as does a suit of clothing or a pair of shoes. When it is depleted of its slippery properties it must be gotten rid of and in this system means for cleaning out the residuum are at hand.

In the system as here depicted the pressure is sufficiently high to maintain the circulation, even against the conditions that obtain when the lubricant is of a poor grade. That any lubricating system is prone to be stopped up by accumulations of paraffine is well appreciated and in the earlier practices this was one of the most prolific causes of trouble. By maintaining a sufficiently high pressure there is no danger from this serious source of trouble. The greatest good comes when the oil is of a proper grade, even if the system can cope with foreign accumulations.

Collins High-Duty Axles

NEW IDEA IN LIVE REAR AXLES; BEVEL GEARS USED FOR TRANSMISSION WORK; LIGHT AND STRONG REAR AXLE UNIT DEPICTED

EXCESSIVE unsprung weight has always been the stock argument against unit types of live rear axles, and that there is something to be said against having too much weight on the live rear axle is now regarded in engineering quarters as a fact. The other side of the question has its advantageous angle, that is to say, practice has sanctioned the placing of the transmission gear integral with the axle. Just why this form of construction works so well is not readily explained, but many of the most silent performers that are to be seen on road and boulevard are built in just this way.

The Collins Axle & Manufacturing Company, Frick building, Pittsburg, Pa., has completed the designs of a line of axles of this class, and the illustrations here offered are made by the wax process from working drawings in order to bring out the real matters of interest and to show that lightness is a pronounced feature, not, however, at the sacrifice of due strength.

In giving this matter thought for the purpose of discriminating, it may as well be remembered that, while the pyramids, for illustration, were made of great strength, at the cost of thousands of tons of material, even granting that they have survived the ravages of time and eaten into centuries, they have ever resided on one spot of earth. Automobiles, on the other hand, as the word implies, are mobile, that is to say they move about.

Even bridges, although they are made of kinetic material, would fall short of the requirement were they to be used in the manner as laid down for automobiles, and, when the situation is properly canvassed, it will be seen that success, from the point of view of the proper design of automobiles, demands that the design be on a kinetic basis.

When the members of a structure, as the columns of a building, are subjected to quiescent loading, as they are, the load is static; there is no shock, vibration, or other consideration, and the static moments are all that have to be taken cognizance of. But if the attention of the reader be attracted to the crankshaft of a locomotive, for purposes of illustration, it will be quite apparent that the character of the load is kinetic, that is to say, the crankshaft is subjected to shock, vibration, alternate bending, and all the other ills which are expressed by the designer as in the category of kinetic moments.

Likewise, in automobile designing, the work is of a kinetic nature, and castings, which are more or less incapable of doing this class of work, should be used but sparingly if at all.

Referring to Fig. 1 of the Collins axle, the shell S1 is of drawn steel, and the method of joining is by means flanging F1, with studded fastenings all around the circle. The spring

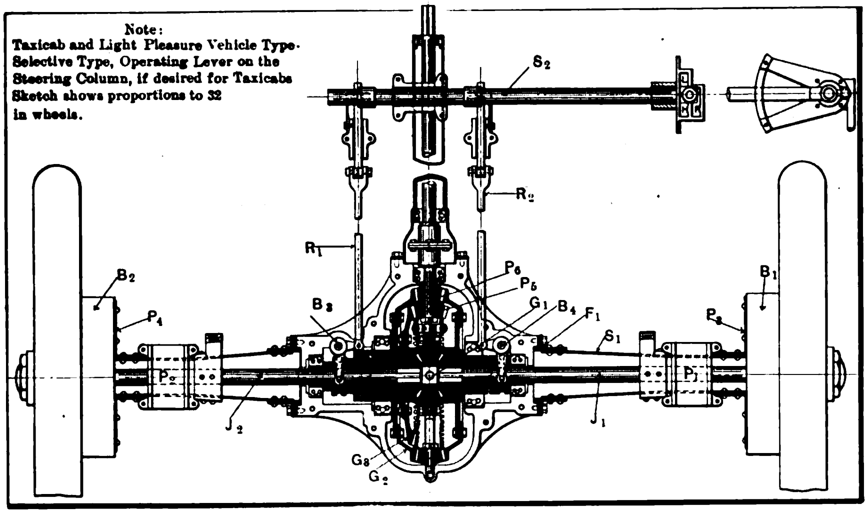

Fig. 1—Type of axle as designed for taxicab and light car work, using bevel gears in the speed change system

perches P1 and P2, are designed to accommodate wide plate springs which is in accord with the practice which is dictated by experience. The brake-drums B1 and B2 are provided with closure-plates P3 and P4, which are flanged to the shell.

The differential gear system G1 is of the bevel type within an oil-tight housing, and the jackshafts J1 and J2 are squared just where they fit into the gears of the differential system.

This axle is made to serve in taxicab work and for light pleasure vehicles. The sliding gear system is composed of a set of bevel gears G2 and G3, meshing with mating pinions P5 and P6. A means is available for withdrawing the gears from the pinions and for keeping one set out of engagement when the other set is working. This plan differs from other types of transmission-gear systems to the extent that bevel gears are used instead of square-cut gears. In the conventional square-cut gear systems it is necessary to clash the gears endwise, that is to say, axially, to engage them; in the bevel gear work the gears are brought into mesh by throwing them together so that contact is all along the faces of the teeth, thus eliminating the chance of over-straining a gear by bringing all the work upon a small portion of a tooth near its end. This gear affords two speeds, forward and reverse.

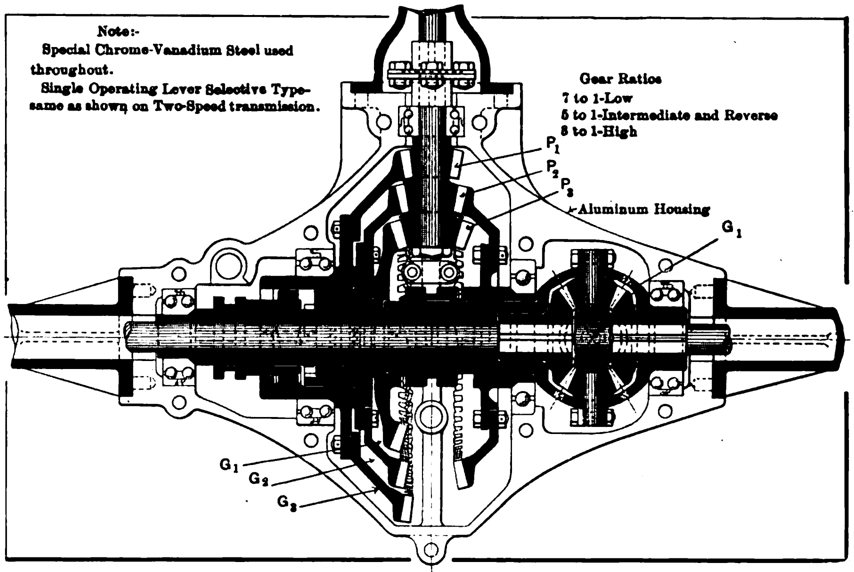

Fig. 2—More pretentious live rear axle with a bevel gear system for speed changes; designed for heavy duty

More Pretentious Type Made Also

As a further indication of the activity of this company reference is had to the larger axle, Fig. 2, with the differential gear incorporated into the system at the right side of the bevel type of sliding gear system. In this case the gears G1, G2, and G3 are nested just as in Fig. 1, but there is one more speed available in this case. These gears mate with the pinions P1, P2, and P3. In both examples the method of sliding the gears to attain the benefit of the respective speeds is just the same as that which is found to be practicable in general practice, as for illustration, the R1 and R2 (see Fig. 1) connect with bell-cranks B3, and B4, for the purpose of shifting the gears, and motion is imparted to the rods by the turning of the shaft S2, which is done by means of side-levers, or which may be accomplished by a pedal.

Construction Includes Fine Grades of Steel

In addition to the elimination of heavy and useless casting material, it was the purpose of the designer to utilize special grades of steel, as chrome-nickel steel in the parts that have to stand the brunt of the work. Heat treatment is resorted to in the process of coaxing out kinetic qualities, and lightness of the rotative parts is a factor to the extent that undue inertia is not a property in the design; this absence of inertia helps to a marvelous degree in the meshing of the gears, not only by reducing clatter which is disagreeable, but the teeth of the gears are saved from the merciless pounding that would otherwise be encountered.

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL CLIMBS, ETC.

Dec. 1...........Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Dec. 31-Jan. 7, '11.New York City, Grand Central Palace, Eleventh Annual International Automobile Show.
Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Manufacturers.
Jan. 16-21, 1911..New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4, '11.Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories, Exclusively.
Feb. 6-Feb. 11, '11.Chicago Coliseum, Tenth National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.
Mch. 4-11, 1911...Boston, Mechanics' Building, Ninth Annual Show, Licensed Automobile Dealers' Association.

Races, Hill-Climbs, Etc

Aug. 31-Sept. 8..Kansas City, Mo., Reliability Run, Auto Club of Kansas City.
Sept. 2-5.........Indianapolis, Ind., Speedway Meet.
Sept. 3-5.........Run and Labor Day Race Meet of North Wildwood Automobile Club.
Sept. 3-5.........Brighton Beach, Two-day Track Meet.
Sept. 5......... Cheyenne, Wyo., Track Meet.
Sept. 5...........Denver, Col., Road Race, Denver Motor Club.
Sept. 5...........Los Angeles, Cal., Speedway Meet.
Sept. 5-10........Minneapolis, Minn., Track Meet at State Fair.
Sept. 7-10........Buffalo, N. Y., Reliability Run, A. C. of Buffalo.
Sept. 9-10........Providence, R. I., Track Meet.
Sept. 10..........Los Angeles, Cal., Mount Baldy Road Race.
Sept. 10..........San Francisco, Cal., Golden Gate Park Road Race, Automobile Club of San Francisco.
Sept. 10-12.......Catskill Reliability Contest and Hill Climb, Motor Contest Association.
Sept. 10-12.......Seattle, Wash., Race Meet.
Sept. 15..........Algonquin, Ill., Annual Hill Climb of Chicago Motor Club.
Sept. 16-26.......Asbury Park, N. J., Aviation Meet, Aero Club of America.
Sept. 17..........Syracuse, N. Y., Track Meet of Automobile Club of Syracuse, Syracuse Automobile Dealers' Association and the New York State Fair Association.
Sept. 24..........Belmont Track, Narberth Race Meet, Norristown Automobile Club.
Sept., middle of...Chicago, Commercial Car Reliability Contest of Chicago Automobile Club.

Foreign Shows and Races

May 1-Oct. 1....Vienna, Austria-Hungary, Automobile and Aviation Exposition.
Aug. 1-Sept. 15...French Industrial Vehicle Trials.
Oct. 15-Nov. 2....Paris, France, Aeronautical Society Show.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

ROAD-WHEELS have a wider influence on autoists and the conclusions they reach regarding the state of the art than any other point in the design.

* * *

JUST in proportion as this part of the car is prominent from the point of view of the attention demanded of autoists they neglect it.

* * *

HUMAN nature seems to be that way; the things that are to be done as a matter of necessity remain undone, or are only taken up when necessity compels.

* * *

INGENUITY is far-reaching, it is true, but the supply of this quality is not always equal to the demand.

* * *

MOST tender of all spots with the average man is his pocketbook; this fact should have more effect upon autoists from the point of view of road-wheels than it does.

* * *

CERTAINLY, it takes a pretty penny to span the tire bill of the autoist who waits for the tires to give out before looking them over.

* * *

TRUE, it is quite an undertaking to remove and replace a 36 x 4 1-2-inch set of tires.

BUT the hard labor that clung so closely to the old clincher idea is only present with the man who fails to note that progress is being made.

* * *

THERE is now no occasion to struggle with a recalcitrant tire on a rusted clincher rim.

* * *

THIS year brings its crop of quick detachable and demountable rims; they are in various forms; choice is there for the most fastidious.

* * *

MUNSEY Historic Tour is over; the veterans of the long trek are returning to their respective homes, and glad of the chance.

* * *

PERHAPS it is not too much to say that the tour is "historic" in more ways than one; the section of country actually covered is rich in historical events; but the tour itself will go down in history.

* * *

AMONG the points of unusual interest lies the perfection that attended the management of the great event; it just goes to show that a large undertaking can be handled properly when the "captain on the bridge" has his ounce of stamina.

* * *

THEN, there is the record; the sum total of result; not merely the noticing here and there of this or that car as having a clean score; such matters will be given proper weight, to be sure.

* * *

AUTOMOBILES, taking them as a whole, stand up to the gruelling test of a long and strenuous run so perfectly that, while penalties may be exacted, the fact remains that they are for happenings that are well within the ability of the average autoist on a basis of making a road-side repair.

* * *

AUTOISTS owe much to the Munsey build of enterprise; it has broad utility for its foundation. The makers of automobiles that went into the run must also recognize the fact that a show-down such as this carries conviction—it is a mark of merit to be in such company even if a penalty is suffered; it is the penalty that comes when a man's fight is being waged with such vigor that a few scratches are the least to be expected.

* * *

GASOLINE is the residence of the energy that makes the automobile go. That it should present a problem or two is a reasonable expectation. So much energy in so small a package represents a giant done up in the gossamer web of the spider.

* * *

FORTUNATELY the composition of gasoline is such that, like the elephant that minds and works faithfully at piling timber for his master, a force is represented that is as docile as it is large.

The Week in Detroit

NEW COMPANIES INCORPORATED; NEW FACTORIES PLANNED AND IN PROCESS OF ERECTION; BRIEF TRADE AND PERSONAL NEWS

DETROIT, Aug. 29—Several new corporations are in the making here. Two or three have filed articles within the past few days; the others will follow suit in due time. Among the former is the Whitney Motor Car Company, with a capital stock of $150,000, which has opened temporary headquarters at 1416 Ford building. It is the company's intention to manufacture a two-cylinder, gearless, friction-drive roadster to sell for about $400. A model car already has been turned out and arrangements are being made to begin work on twelve other machines within the next month.

The officers of the Whitney Motor Car Company are: President, Brock C. Eby; vice-president, J. C. Hudson; secretary, H. C. Whitney; treasurer, George O. Tackles.

Detroit has had its first glimpse of the latest novelty in motor vehicles, the three-wheeled commercial car. The inventor, W. G. Wagenhals, has come here from St. Louis, Mo., and is trying to interest local capital in the organization of a company to make his machine.

Mr. Wagenhals has figured out that he can put his car on the market at $650.

If plans now under way materialize, the motor car may take a leading part in the settlement of Detroit's vexatious street-car problem. Adolph Gerhard, a former justice of the peace in Hamtramck township, is promoting a $100,000 corporation to operate a system of automobile bus lines in competition with the Detroit United Railway, carrying passengers at three cents a head and giving them transfers in the bargain.

The Culver Chain Company has been incorporated with a capital stock of $50,000, the principal stockholders being William Culver and Arthur Taylor, both of this city. The company has secured a building at 140 and 142 Madison avenue for manufacturing purposes and expect to begin operations shortly.

Two tire companies are among the recent incorporations. The Puncture Proof Tire Company already has opened for business at 229 Beaubien street. It manufactures pneumatic and solid tires for commercial vehicles as well as for pleasure cars. L. J. Haynes is secretary and treasurer of the concern. Another company with a puncture-proof proposition is the Cooley Automobile and Tire Co., which filed articles of association with the Secretary of State last week, and which will locate in Detroit. John B. Chaddock is president; L. D. Cooley, vice-president and general manager; F. H. McMullen, secretary, and B. C. Bastedo, treasurer. These, with George A. Erskine, constitute the board of trustees. The capital stock is $50,000.

The recently-organized Universal Motor Truck Company filed articles with the Secretary of State during the past week, capitalizing at $350,000. Work is already under way on its factory, which will be located on the Grand Trunk railroad, between Farnsworth and Thedore streets, in the northeastern section of the city. The site comprises three and one-half acres.

The Van Dyke Motor Car Company has turned out its first cars, the cars finding a ready sale. By fall the output will be 25 cars a day, it is announced.

Ground will be broken this week for a $30,000 addition to the plant of the Ford Motor Company, Ltd., of Walkerville, Ont., located on the river front in Walkerville. The plans call for a two-story building of reinforced concrete, 70 by 40 feet, with basement, which will be used as a machine shop. The first and second floors will be given over, respectively, to the brazing and painting departments. The addition will give the company 20,000 extra square feet of floor space. The Ford company's new sales building at Woodward avenue and the East Grand Boulevard begins to loom up very conspicuously. The concrete supports for the third floor are now being put in.

A total of 1,275,000 square feet floor space is represented by the six largest motor car and accessory plants now in course of erection in the city, some of which are nearing completion. This is distributed as follows: Dodge Brothers, 367,000 square feet; Alden Sampson Company, 316,000; Lozier Motor Car Company, 200,000; Hudson Motor Car Company, 200,000; Anderson Carriage Company, 100,000; Anderson Forge & Machine Company, 92,000.

Following the reorganization of the Abbott Motor Car Company the plant has been closed down for two weeks for an inventory and a complete audit of the books. M. J. Hammers, the new general manager, will familiarize himself with the details and will collaborate with the department managers in mapping out plans for the coming year.

A number of changes in administrative positions are chronicled. James Bourquin leaves the Chalmers Motor Company, where he has been superintendent, to become general factory manager of the Paige-Detroit Motor Car Company, which recently increased its capital stock from $100,000 to $250,000. Mr. Bourquin is a graduate of the engineering department of the University of Michigan, '04, and entered the employ of the Chalmers company when it was organized as the Thomas-Detroit. Previously he was associated with the Olds Motor Car Company in Lansing and before that with the Peerless Motor Car Company in Cleveland.

Edward H. Broadwell, vice-president of the Fisk Rubber Company, has become identified with the Hudson Motor Car Company in an important capacity. He has acquired considerable stock in the company and has been elected vice-president. As such he will have charge of the selling end. He will assume his new duties September 1.

Edward R. Hewitt, of New York, son of a former mayor of the metropolis and designer of the Hewitt truck, comes to the Metzger Motor Car Company's plant in the near future as technical expert. He is a brother of Peter Cooper Hewitt. The Metzger company now has 600 men at work and expects to be running full capacity by September 1.

Close on the heels of the estimate of 500,773 as the population of Detroit and its nearest suburbs, given out by R. L. Polk & Company last week, comes the official announcement from Washington that the census returns give Detroit alone, without its suburbs, 465,766 people, an increase of 63 per cent. since the last census. For this remarkable showing the automobile industry receives a large share of the credit, as previously indicated.

The Detroit Shock Absorber Company already has been organized with a capital of $5,000 to start with and articles have been filed in Lansing, with the Secretary of State. It is a close corporation, all the shares having been taken by the projectors, F. B. Hibbler and Maximilian K. Golden, who is the inventor of the device.

The Golden absorber is a V-shaped affair, the bottom of the "V" forming a circle, however. One of the arms is attached to the upper part of the spring and the other to the lower part. When the springs are suddenly compressed the arms come together, but a friction band, which may be adjusted to conform to the tension of the spring, causes the latter to recoil gradually. The inner construction is simple, consisting of a locking device operating on the wedge plan. Patents have been applied for. Mr. Hibbler is president and treasurer of the company and Mr. Golden is secretary and general manager.

Lewis A. Austin has resigned as secretary and assistant manager of the Autoparts Manufacturing Company, of Detroit, and after September 1 will be connected with the Western Motor Company, Logansport and Marion, Indiana. Mr. Austin's headquarters will be at Logansport.

Notes on Aviation

BY MARIUS C. KRARUP. A MISSING PRIZE—DELUSIONS OF SCIENCE—GOOD MATHEMATICS WASTED—LIFTING POWER OF HELICOPTERS—ASTRONOMY WANTED AND CLEAN LIVES—EXIT STABILIZER

IN all reports of aviatic performances during the past week the record of one fact or condition more important for judging the value of the performance than all the other facts combined is omitted. The state of the weather is given in generalities only and in terms which may be interpreted as the reader's enthusiasm or distrust dictates. A device to be attached to the aeroplane machine and suitably arranged for producing an automatic record of attacks by irregular atmospheric currents has not yet been invented. No prize has as yet been offered for a device of this nature, which should preferably be so arranged that the curve or curves plotted by it could be rendered in the telegraphic alphabet and reproduced by the receiver.

Aero scientists, as Lanchester, Finsterwalder, Wegner-Dallwitz and even Bendemann, assume that the force required for flying may be calculated according to the acceleration of the volumes of air affected by the thrusts, ignoring that the thrusting of an elastic gas against an infinite body of the same gas involves considerations almost entirely new in physics and incomparable at nearly all points to the motions of solids or liquids. But improvements in aeroplane physics will go on just the same in practice, while acceleration of air in air will remain an inapplicable conception, quantitatively and qualitatively; a mere empty concatenation of words to which there is nothing corresponding in reality; a "phantom thought."

Three pages of perfectly good mathematics in an esteemed European contemporary were recently devoted to the following puzzle: "An airship moves with a speed of 15 meters per second and creates thereby an air resistance of 75 kilograms. As one horsepower overcomes a resistance of 75 kilograms with a speed of one meter per second, there will in theory be 15 horsepower required for moving the airship. How many are now in reality used?" Students of aviation please prepare a diagram of the errors in the mathematician's premises and an estimate of the value of mathematics based thereon.

In experiments with co-axial helices of 6 and 8 meters diameter, a vertical traction effort of 530 kilograms has been obtained by Klingenberg through the employment of 93 horsepower, according to a detailed statement by the experimenter in *Zeitschrift des Vereines Deutscher Ingenieure* of June 18. With a 100 per cent. power transmission efficiency the traction effort should have been about 1,500 kilos.

To use a compass for guidance in crossing the Atlantic or any other wilds uncharted for aviation, with a craft which follows no keel, may have its difficulties, but there is a clear sky above the clouds, with sun or stars visible. Aviators must study astronomy, practice deep breathing and shun catarrhs.

There is a job waiting in aviation for every chauffeur who has lived so intelligently and decently as to endure a rise in altitude of two miles in one-half hour without mental and physical discomfort. The plums hang high for the airman.

Since the recent aviation meet at Reims the Voisin biplanes have been made without the vertical partitions which had been supposed to be "stabilizers." The change was introduced under guise of a "racing model."

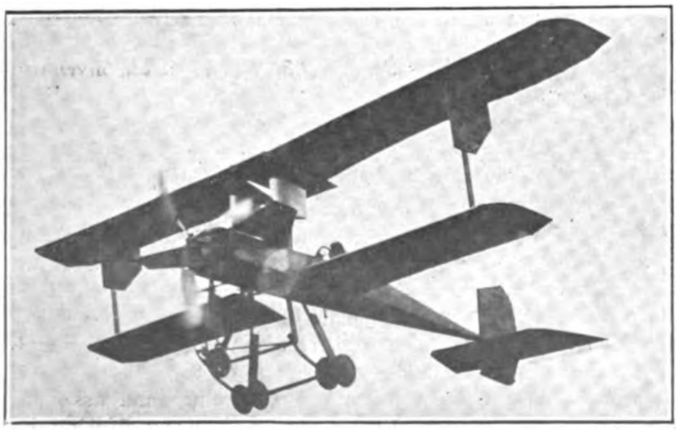
Prayers are heard to the effect that there will be no great need of rubber in aeroplanes. It is high enough.

Aviation News of the Week

BREGUET CONSTRUCTION IN PERFORMANCE—NEW ALTITUDE RECORD—WRIGHT FLIERS IN ATLANTIC CONTEST—WIRELESS MESSAGES

CABLEGRAMS from Lille, France, announce that Louis Bréguet took up five passengers on August 29 on his biplane, sustaining a load, including the gasoline, of 921 kilograms, equaling 2,026 pounds.

The Bréguet biplane differs radically from all other French machines. It is a double monoplane rather than a biplane, as the two supporting surfaces, of which the upper one is of much the larger area, are not stiffened one against the other by a number of uprights but only by two steel tubes at the small central section which carries the motor equipment and load, and by one similar steel tube on each side, arising from near the extremities of the lower plane. The air resistance is thereby reduced and the wings are rendered flexible. The ribs of the wings are of sheet aluminum pressed into U-shape and secured to a steel tube running the length of he wing. The upper wings are warped automatically and take different angles under the influence of the wind and at turns. Two lateral winglets are under control by the driver and two horizontal rudder surfaces in the rear serve to maintain the fore-and-aft balance. All the controls are obtained by means of a single steering wheel and post, the latter being jointed to admit of a rocking motion. The skeleton of the machine is entirely in trussed steel tubes supported on the ground by means of a wheeled chassis mounted in a special pneumato-hydraulic suspension. The power is derived from a 55-horsepower Renault aviation motor with eight cylinders, air-cooled and placed in V-shape, four in each branch of the V and the branches 90° apart. As tried in a recent contest conducted under the auspices of the Automobile Club of France by Mr. Lumet, this motor developed a little more than 60 horsepower and its weight was 179 1-2 kilos. In the Bréguet machine the motor is placed well forward and the three-bladed aluminum propeller in front of it, while the aviator and passengers are seated behind. The propeller shaft is geared down to reduced speed by mounting it on the camshaft of the motor, and the aluminum propeller blades are flexibly mounted upon three steel arms secured to the shaft. Starting of the motor and the machine is effected from the aviator's seat by means of a starting crank.



The Breguet double monoplane which carried six persons in flight Aug. 29 at Lille, France

The Gnome motor has recently been produced in a new form in which the intake valves are mechanically operated and placed in the heads of the cylinders. The Gnome motor previously had automatic intake valves in the pistons, drawing the mixture from the crank chamber.

Managers of the aviation tournament to be held at Belmont Park, N. Y., announce that there will be prizes at the meet to the value of $50,000 and that, in addition, the contestants will get a share in the net revenues on some plan approved by them.

In a flight on August 29 Léon Morane, flying a Blériot machine, ascended to an altitude of 6,692 feet at Havre, France. This record was approved by the judges. J. Armstrong Drexel had reached the height of 6,752 feet in a Farman machine on August 12, at Lanark, England, and the Kew Observatory had verified this reading on August 20 by testing of the barograph carried by Drexel. The French judges, however, demand ocular as well as instrumental evidence for the establishment of a record. Brookins holds the American record of 6,275 feet made with a Wright machine at Asbury Park.

Preparations for the attempt by Walter Wellman, of Washington, D. C., and A. Vaniman, his technical assistant, to cross from Atlantic City, N. J., to some point in Europe by means of the almost dirigible balloon "America" are being actively carried on, and it is expected that rehearsals for the start can begin in ten days and that the departure may take place shortly thereafter. The filling of the great bag with hydrogen is almost completed but will be supplemented later to make up for leakage.

At the Harvard-Boston meet, to be held at Atlantic, Mass., September 3 to further notice, the three aviators, Brookins, Johnstone and Hoxsey, who fly Wright machines, will try conclusions with fliers of rival machines, this being the first occasion for the Wright corporation to enter into public contest against other machines claimed to infringe the Wright patents.

The new "headless" Wright flier shown at Asbury Park and reputed capable of carrying five persons has not developed any speed superior to the records made with other fast machines, particularly some French monoplanes and the Curtiss biplane, but then it has not been equipped with a motor of high power commensurate with the area of its supporting surfaces. It is believed it will be so equipped for the impending Harvard-Boston meet at Atlantic, Mass.

Experiments in receiving and dispatching wireless messages from an aeroplane in flight, such as were begun at Sheepshead Bay last week, will be continued at Hammondsport, N. Y., this week and thereafter. H. M. Horton has devised a sending apparatus and Lieutenant Culver, attached to the Signal Corps of the Department of the East, devised a receiving apparatus which was tried at Sheepshead Bay by J. A. D. McCurdy on the latter's Curtiss biplane. Lieutenant Culver and aviator McCurdy will conduct the experiments at Hammondsport, in both receiving and sending, and the results will be reported to the War Department.

J. C. Mars, one of the aviators who entertained the public last week at Sheepshead Bay, near New York, undertook to fly across the lower bay to Staten Island and rose to a height of about 2,000 feet, when a pump lever which he worked with his foot in order to supply the motor of his Curtiss biplane with extra lubrication, on the same plan as is followed in automobile racing machines, broke and the motor stopped working. The machine fell into the sea with considerable speed, but Mars was saved by the timely arrival of a tug boat.

Communications

VERY FEW HOUSES MORTGAGED TO BUY AUTOMOBILES; WANTS A NATIONAL LICENSING LAW FOR AUTOMOBILISTS; AFFORDING THE LATEST VIEWS IN RELATION TO THE EXPEDIENCY OF OWNING AN AUTOMOBILE

Very Few Homes Mortgaged to Buy Automobiles—For the purpose of arriving at the true facts and obtaining exact information relative to the rumors which have been so persistently circulated by some bankers, that automobiles were purchased by the wholesale with money secured by mortgaging homes, letters have been written to 24,000 bankers in the United States and enclosed was a blank form asking the bankers to state the number of people in their vicinity who had mortgaged homes or who had borrowed money to purchase automobiles, The bankers to state, to the best of their knowledge, the percentage of motor cars used for business or useful purposes and whether or not in the bankers' opinion the sale of automobiles would increase in their respective territories.

Replies have been received to date from 4,830 bankers who state that there are 198,216 automobiles in their cities and towns. Of this number only 1,254 have been purchased by the placing of mortgages and only 7,475 have borrowed money without mortgage to purchase automobiles. In the opinion of 3,229 bankers, the sale of automobiles will increase during 1911 over that of 1910, while 1,601 say the sales will not increase.

With less than one per cent. of automobiles bought on mortgages and less than 4 per cent purchased with borrowed money, recent claims of alarmists are conclusively proved to be practically without any foundation whatever.—Benjamin Briscoe, President United States Motor Company.

Wants a National Licensing Law for Automobilists—The man who operates a locomotive on a steel, perfectly protected road must be a man without blemish—you might say, almost the perfect physical man, and well balanced mentally. What kind of persons are allowed to drive automobiles on roads which may never have been leveled off or worked, which are allowed to go for months, yes, years, without any attention? Stones, rubbish, and all sorts and conditions of things allowed to accumulate thereon, all varieties of animal life allowed to roam at will on the road, endangering their own as well as other lives. The State will license any person over eighteen years of age to operate automobiles of any power or capacity, without regard to the physical and mental ability or disability of the driver. Such machines are certainly much more hazardous than locomotives. There must be better regulation of this rapidly growing sport and occupation. Lives must be safeguarded and the only effectual remedy is a national automobile law. Not only should a national automobile law fix the license fees, but it should be framed on just as stringent lines as the rules governing promotion of fireman to the rank of locomotive engineer. Only persons free from physical disability, and of sound mind, should be allowed to drive motor cars, and all should be compelled to pass a real, not a "fake," examination and undergo just as strenuous a medical examination as locomotive engineers and applicants for life insurance.

I always feel, when driving my car, that I am perfectly capable of taking care of myself and friends, and that I have absolute control of the car. I know the car because I live with it and keep it lubricated and in good running order all the time. But I am afraid of the other fellow. The fellow who always feels that he must pass you on the road. The fellow who dashes madly through town and city streets. The fellow who turns his corners as though the entire mechanism of the car was as sturdy as a battleship. The fellow who keeps his cut-out open day and night, in town or in the mountains. Those are the persons who will compel the Government to act in their own defense, for they do not seem capable of caring for themselves or safeguarding their fellow men. Welcome the day when Congress awakes to the necessity and passes a good national automobile law that will assure the utmost safety to citizens.—Allan Dale, Little Silver, N. J.

Standardization Coming

SOCIETY OF AUTOMOBILE ENGINEERS HAS APPOINTED COMMITTEE TO TAKE THE INITIAL STEP TOWARD THAT END

Following the decision made at the meeting of the S. A. E. at Detroit last month, the Standardization Committee of the Society has been organized: Howard E. Coffin, Pres., S. A. E.; Henry Souther, Hartford, Conn.; James H. Foster, Hydraulic Pressed Steel Co., Cleveland, O.; H. S. White, Detroit Seamless Steel Tube Co., Detroit, Mich.; Charles T. Jeffery, The Thomas B. Jeffery Co., Kenosha, Wis.; Elwood Haynes, The Haynes Automobile Co., Kokomo, Ind.; H. W. Alden, The Timken-Detroit Axle Co., Detroit, Mich.; Arthur Holmes, The H. H. Franklin Manufacturing Co., Syracuse, N. Y.; W. H. Van Dervoort, The Moline Automobile Co., East Moline, Ill.; D. F. Graham, The New Departure Manufacturing Co., Bristol, Conn.; G. E. Merryweather, The Motch & Merryweather Machinery Co., Cleveland, Ohio; A. C. Bergman, Simplex Automobile Co., New York; Coker F. Clarkson (secretary), 1451 Broadway, New York. It is the expectation to add to this list of committeemen as the occasion demands—the subject is a big one.

On August 22 the following new members were elected: Fred-Wm. Blanchard, Faulkner-Blanchard Motor Car Co., Detroit, Mich.; T. P. Chase, Chalmers Motors Co., Detroit, Mich.; Edward W. Curtis, Jr., Studebaker Bros. Mfg. Co., Chicago, Ill.; Henry L. Barton, Metal Products Co., Detroit, Mich.; DeWitt Clinton Cookingham, Rauch & Lang Co., Cleveland, O.; Geo. William Cooke, Pierce-Arrow Motor Car Co., Buffalo, N. Y.; Wm. Morris Davis, E. R. Thomas Motor Co., Buffalo, N. Y.; H. W. Gillett, Mgr., The Aluminum Castings Co., Detroit, Mich.; Edward Dixon, Thos. B. Jeffery & Co., Kenosha, Wis.; Frank E. Ferris, Brush Runabout Co., Detroit, Mich.; Starling Henry Humphrey, Brush Runabout Co., Detroit, Mich.; Geo. N. Hickey, Van Dyke Motor Car Co., Detroit, Mich.; Wm. H. Hogle, Brush Runabout Co., Detroit, Mich.; Harold H. Kennedy, The Waverly Co., Indianapolis, Ind.; Fritz Loeffler, Waldhof Fellstoffabrik, Manheim, Waldhof, Germany; Ralph L. Morgan, Ralph L. Morgan Co., Worcester, Mass.; Horace Henley Newson, McCord Mfg. Co., Detroit, Mich.; George L. Norris, American Vanadium Co., Pittsburg, Pa.; Charles R. Short, G. & E. Power Co., Philadelphia, Pa.; Nicholas Shamroy, Landau & Golden, New York City; Charles B. Rose, Velie Motor Vehicle Co., Moline, Ill.; Wm. H. Reddig, Chalmers Motor Co., Detroit, Mich.; Geo. A. Weidely, Premier Motor Mfg. Co., Indianapolis, Ind.; Clyde W. Stringer, Brush Runabout Co., Detroit, Mich. *Associate Membership.*—Albert F. Rockwell, The New Departure Mfg. Co., Bristol, Conn.; Winfield DeWitt Rhentan, The White Company, Cleveland, O.; R. A. Radle, Clark Sales Co., Detroit, Mich.; Thomas Towne, Ideal Opening Die Co., New York City; Walter Webster Totman, Whitney Mfg Co., Hartford, Conn.; George S. Morrow, Stepmey Spare Wheel Co., Chicago Ill.; Henry May, Pierce-Arrow Motor Car Co., Buffalo, N. Y.; Frank E. Couch, 316 Hudson Street, New York City; Charles F. Case, Oliver Motor Car Co., Detroit, Mich.; Clyde E. Dickey, Denman & Davis, New York City; Wellington F. Evans, Metal Products Co., Detroit, Mich.

Good Fields for Vanderbilt and Grand Prize

The Vanderbilt Cup race, one of the most notable speed competitions of motordom, will start at dawn October 1. The course is laid out over the Long Island Motor Parkway and is one of the fastest road courses in the United States.

The turns will not be banked this year as they have been in the past, but will be widened in several instances. The Massapequa turn, which is on an acute angle, will necessarily be banked, but it too will be materially broadened. Practice over the course will begin September 20.

Entries for the event so far received are as follows:

VANDERBILT CUP

Car	Driver	Entrant
Simplex	Ralph E. Beardsley	Simplex Auto Co.
National	Not named	National Mot. Veh. Co.
Alco	Harry F. Grant	American Loco. Co.
Benz	D. B. Brown	Benz Import Co.
National	Not named	National Mot. Veh. Co.
Simplex	L. A. Mitchell	Henry B. Harris
Pope-H'f'd	Not named	B. C. Fincke
Pope-H'f'd	Not named	H. Emil Holt
Benz	Edw. Hearne	Benz Import Co.
Benz	Geo. Robertson	Benz Import Co.

MASSAPEQUA SWEEPSTAKES

Cole "30"	Endicott	Cole Motor Co.

For the Grand Prize race to be held October 15 there are entered to date fourteen cars of American and foreign manufacture, as follows:

GRAND PRIZE

Car	Driver	Entrant
Alco	Harry F. Grant	Amer. Loco Co.
Benz	B. Oldfield	Benz & Company
Benz	Victor Hemery	Benz & Company
Benz	Geo. Robertson	Benz & Company
Fiat	Louis Wagner	Fiat Auto. Company
Fiat	Ralph De Palma	Fiat Auto. Company
Fiat	Felice Nazarro	Fiat Auto. Company
Marmon	Not named	Nordyke-Marmon Co.
Marmon	Not named	Nordyke-Marmon Co.
Marmon	Not named	Nordyke-Marmon Co.
Marq.-Buick	L. Chevrolet	Marquette Motor Co.
Marq.-Buick	Robert Burman	Marquette Motor Co.
Marq.-Buick	A. Chevrolet	Marquette Motor Co.
Roebling-Planche	W. A. Roebling, 2d	W. A. Roebling, 2d

Premier Representatives in Convention

The annual gathering of representatives of the Premier Motor Manufacturing Company was held in Indianapolis Tuesday, Wednesday and Thursday of last week. Among the social events of the convention was a luncheon at the Columbia Club Tuesday noon followed by a banquet at the same place that evening. On Wednesday there was an automobile ride around the city, followed by a clam bake at Broad Ripple.

The guests of the company during the meeting were: R. M. Owen, New York; R. E. Ingersoll, New York; G. B. Kimball and R. I. Eads, Boston; John Guy Monihan and Allen Sheldon, Philadelphia; Mr. Avery and W. E. Stalnaker, Chicago; C. E. Gibson, O. G. Meyers and Lee Burns, Indianapolis; Elmer McConaha, Richmond, Ind.; H. P. Mammen, Evansville, Ind.; Louis Schwaebe, Los Angeles, Cal.; F. D. James, Tampa; H. O. Bell, Spokane; H. A. Bowman, Little Rock, Ark.; A. F. Chase, Minneapolis; H. L. Bracken, Salt Lake City; G. E. Ayres and J. F. Minton, Jr., Houston, Tex.; H. D. Walker, Greenwood, Tenn.; H. C. Stricker, Cincinnati; G. E. Schmitt and Fred Schmitt, Hamilton, Ohio; Edward Miller, Columbus, Ohio; W. C. Rowe, Beverly, Mass.; John O'Donnell, Providence, R. I.; C. C. Lake, Kansas City; Mr. Michiel and C. H. Martin, Pittsburg; H. P. Stratton, Petersburg, Va.; F. P. Miller, Jacksonville; B. D. Kent, Oklahoma City; W. D. Sanders, Columbus, Miss.; F. L. Riggs, Chattanooga; H. L. Ramsey and J. A. Dugan, Louisville; H. B. Pinkerton, Peoria, Ill.; W. J. Casterton, Detroit; J. H. Fleming, Scranton, Pa.; Thomas Neet, Versailles, Ky.; H. M. Allen, Lewiston, Mont.

Unconfirmed rumor has it that there will be a race meeting at the Brighton Beach race track Saturday and Monday, September 3-5. A number of well known racers are said to be entered, but the most painstaking investigation failed to show more than two that had been definitely made up to Wednesday afternoon.

The Capital's First Hill Climb a Success

WASHINGTON, D. C., Aug. 30—The first hill climb ever held in Washington took place to-day on Nayors Hill, under the auspices of the Automobile Club of Washington, and was a big success. The hill, an incline of ten degrees in seven-tenths of a mile, was in splendid condition and while the majority of the drivers were amateurs the time made was good.

A Buick 16, driven by T. C. Johnston, carried off the premier honors of the day by winning the free-for-all event, negotiating the distance in 49 1-5 seconds, the fastest time made during the day. Summary:

Car	Driver	Time
CARS LISTED AT $800 AND UNDER		
Krit	Thomas Cadick	1:35:05
Hupmobile	E. Hamilton	1:39
Krit	K. Crittenden	1:40 3-5
Maxwell	B. Robertson	1:52 2-5
Hupmobile	H. N. Brown	2:00
CARS LISTED AT $801 TO $1,200		
Warren-Detroit	Tom Berger	1:03 4-5
Ford	C. E. Miller	1:13 4 5
Oakland	H. Bauer	1:20
Ford	E. J. Drake	3:00
CARS LISTED AT $1,201 TO $1,600		
Buick	W. Angle	1:09 2-5
Warren-Detroit	G. W. Wells	1:11
Parry	I. C. Barber	1:11
Petrel	A. Llano	1:15 1-5
Warren-Detroit	N. Bowles	1:21
Regal	Arthur Laroche	1:25
CARS LISTED AT $1,601 TO $2,000		
Buick	W. Kronkite	1:02 1-5
Oakland	H. Bauer	1:02 3-5
Buick	G. G. Hamner	1:07
Apperson	G. Orme	1:13 2-5
Buick	G. Halstead	1:18
Apperson	J. J. Fister	1:19
CARS LISTED AT $2,001 TO $3,000		
Matheson	W. B. McBurney	1:03 2-5

Palmer-Singer	F. L. Lescault	1:02
Warren-Detroit	T. Berger	1:05

Safe Handling of Gasoline

(*Continued from page* 356.)

It would not be a paying investment, for illustration, to buy in "car lots" just to realize a small saving over the price of gasoline in barrel packages. The difference in price is not sufficient to compensate for interest on the investment together with the chances of deterioration, even if the means at hand for the storage of the fuel be up to the most fitting requirement. If an owner keeps a single car in commission, it is very likely that the storage tank will be sufficiently large if it will hold one barrel of the fuel. Should the demand be on a basis of two, three, or five cars, as is frequently the case in the more pretentious establishments, the capacity for the storage of fuel should be increased accordingly, but it is not believed that it would be wise to add capacity in direct proportion to the number of cars in commission. It is more than likely that the following will hold:

PROPOSED CAPACITY FOR STORING AUTOMOBILE GASOLINE

Number of Cars in Commission	Capacity of Tank in U. S. Gallons
1	50
2	50
3	100
4	100
5	150
6	150
8	200
10	250

The plan that seems to work the most efficaciously and preserve the gasoline for the longest time, is depicted in Fig. 1, in which T1 is the gasoline tank sunk beneath the grade, outside of the line of the garage. The tank is filled through the filler pipe, F1, after which the cover, C1, is screwed into place and the lock, L1, is then used so that the owner will have control of the supply. The tank is ventilated by the fitting V1, which is connected to the tank at a point near the middle, using the pipe A1. The supply of gasoline is pumped to the gasoline tank of the automobile through the connection C2, by the measuring pump, P1, utilizing the suction connection, S1, which leads to the tank at a point near the end.

That the gasoline should be filtered as it is taken from the "package" and spilled into the storage tank is said to be a pressing need, and one of the devices used for this purpose in practice is depicted in Fig. 2, which, by spiral action and segregation, cleans the gasoline and permits of eliminating the sediment by cleaning out the filtering device as the occasion requires.

Problem of the Garage Involving Fuel

When garages are considered, the situation has to be handled somewhat differently; it is not possible there to bring all the cars to be supplied within a reasonable distance of the pump, and the supply may best be handled by means of a portable tank with a measuring pump attached to it. Just such a tank is here illustrated as Fig. 3. As will be observed, the tank, T1, is of convenient size and is fitted to wheels, W1, with casters, C1 and C2, at the front and a handle, H2, for the operator to grip when the car is being rolled about the garage floor. Gasoline is run into the tank through the filler opening, F1, and when it is filled the tank is locked, a padlock being applied for the purpose. By means of the pump, P1, gasoline is forced into the gasoline tank of the automobile requiring fuel, through the hose, H1, to which a suitable terminal valve, S1, is fitted, the idea being to be able to reach the filler of the tank of every make of car, and to be able to stop off the flow of gasoline quickly when the tank is full, in order to abort the spillage of gasoline on the floor of the garage. The pump is manipulated by turning the crank, C3. These facilities for storing and handling automobile gasoline are made by S. F. Bowser & Co., Fort Wayne, Ind., from whom the illustrations were procured.

Barry's French isn't up to much, but he is a well lubricated mechanic. It takes a brave man to face a stern world in which the greatest necessities are spelled out in a foreign tongue. Barry thinks an automobile is classed as A on the list of necessities, and coupling the car up to its little sisters, the garage, and gasoline, Barry contributes the rest, being a capable machinist, so that his use of the alphabet is by way of listing the first necessities of humanity in the manner as follows: (A) Automobile, (B) Garage, (C) Gasoline, and (D) Machinist—Barry. The sign over Barry's little garage is, therefore, a little shy on the arrangement of the letters, which does not interfere with his enterprise, and that he will make a go of it is taken for granted. Barry, being honest, and a good machinist, has a firm grip on the two principles that spell success.

French Commercial Trial

COMMERCIAL motor manufacturers of France are now engaged in a competition having the advantage of allowing all to be winners. The test is a military one, organized by the Automobile Club of France at the request of the army authorities. The army must have commercial vehicles for its transport service, but instead of buying them outright it prefers to offer subsidies to private owners of an approved type of vehicle, on the understanding that the owners will present the vehicle for active service when called upon. It is in order to decide which are the most suitable types that the competition is being held.

Thirty-six vehicles, entered by nine different firms, are taking part in the trials. In addition there are two competitors in the omnibus section. There being no subsidies here, and little demand for 'buses outside the Paris General Omnibus Company, the response has not been hearty. Because of the army requirements, the thirty-six trucks entered for the competition show a large amount of similarity. They are in two distinct classes, carrying respectively two- and four-ton loads, but in many cases the difference between the two models is slight.

In addition to road capacity, the army fixes the size of the wheels, the width of tires, the road clearance, the size of the platform body, the ratio of weight to useful load; also it insists on protection for the driver, accessibility of all organs, protection of the radiator, hooks front and rear for hauling or being hauled, economy in fuel and lubricant, and the use of some device to prevent the vehicle running backward on a grade. It is because they are bound by these requirements that a certain similarity exists between the vehicles produced in entirely different factories.

The great majority of makers prefer to put their motors under the driver's feet. This is really not obligatory, but as the army requirements stipulate a platform of 11 feet 6 inches in length, it is difficult to find room for the motor under a bonnet. While there are plenty of details that could be improved under the heading accessibility, the average standard is high. The motors have profited by the improvements carried out on touring car models, with the result that piping is reduced to a minimum, valve stems are enclosed, electric wires are passed through a tube, the magneto is under a cover, and the under pan can be readily dismounted.

As three distinct fuels have to be employed—gasoline, alcohol and benzol—and as economy forms the basis of classification, considerable attention has been paid to carbureters. In the majority of cases the makers adopt some standard type and modify it according to their own ideas. Warming either by the exhaust or by the circulation water is adopted in every case, while many of the cars, in addition, have supplementary hand-controlled additional air supply. Only one type of ignition is now employed, namely, high-tension magneto, with, for every firm but one, a fixed sparking point. There is not a set of storage batteries to be found on the whole 36 vehicles. Lubrication, in the majority of cases, is assured by pressure feed to the main bearings, with in some cases the addition of troughs for the connecting rod ends.

A preference is shown by the army authorities for steel-shod wheels in place of solid rubber. The majority of manufacturers, however, believe that greatest economy is to be gained by employing solid rubber, the bandages being single for the front wheels and double for the rear. Only Delahaye and Malicet & Blin have boldly adopted metal bandages for both front and

THIRTY-SIX VEHICLES, REPRESENTING NINE DIFFERENT FIRMS, NOW BEING TRIED OUT UNDER ARMY AUSPICES TO DETERMINE UTILITY

rear wheels of their three-ton trucks, sticking to rubber for the smaller two-ton models. Berliet uses rubber for the front wheels and metal for the rear ones, thus making the economy of one pair of tires, and the same is done for the front-drive Latil; as these latter have no mechanism behind the dashboard, comparison is not possible. In connection with the steel bandages of the Delahaye trucks, it is interesting to note that two sets of superimposed springs are employed, the upper set being much lighter than the lower set. When running light the upper leaves carry the weight of the vehicle, and when fully loaded they are depressed until they come in contact with the lower set, the two pairs then working together as one. The arrangement appears to work to advantage, for it is obvious that the same stiffness of springs is not required for an empty platform as for the same platform with a three- or four-ton load on it.

As a test the vehicles have to pass one month on the road, running singly, in convoys, with and without load, and maintaining an average speed which in no case will exceed 15½ miles an hour. The daily runs will have to be made with gasoline, alcohol and benzol as fuel, the consumption being controlled on certain days and the amount of lubricant noted throughout the competition. The final basis of awards will be made on economy with these three fuels.

The following table shows the sizes of the motors engaged in the competition and the official weight of each vehicle fully loaded and without useful load. Under the latter heading is comprised the vehicle with all spare parts considered necessary, all tanks filled, bodywork, and driver.

THREE-TON SECTION

Maker	Motor	Weight empty, lbs.	Weight loaded, lbs.
1—Malicet & Blin	4 cyl. 90 x 120	6,613	13,522
2—Malicet & Blin	4 cyl. 90 x 120	6,613	13,592
5—De Dion-Bouton	4 cyl. 100 x 130	6,366	13,299
6—De Dion-Bouton	4 cyl. 100 x 130	6,520	13,261
7—Front-drive Latil	4 cyl. 105 x 140	6,425	13,546
8—Front-drive Latil	4 cyl. 105 x 140	6,458	13,646
13—Peugeot	4 cyl. 90 x 120	6,406	13,107
14—Peugeot	4 cyl. 90 x 120	6,426	13,346
18—Delahaye	4 cyl. 100 x 160	6,606	13,457
19—Delahaye	4 cyl. 100 x 160	6,113	13,514
22—Panhard-Levassor	4 cyl. 91 x 130	6,462	13,553
23—Panhard-Levassor	4 cyl. 91 x 130	6,534	13,566
26—Berliet	4 cyl. 100 x 140	6,595	14,651
27—Berliet	4 cyl. 100 x 140	6,593	14,631
35—Delaugere-Clayette	4 cyl. 90 x 120	6,595	13,073
36—Delaugere-Clayette	4 cyl. 90 x 120	6,613	13,007

TWO-TON SECTION

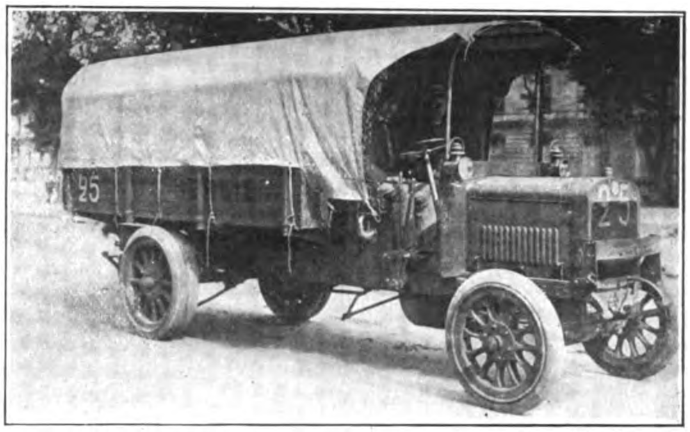
Maker	Motor	Weight empty, lbs.	Weight loaded, lbs.
3—Malicet & Blin	4 cyl. 90 x 120	6,450	12,235
4—Malicet & Blin	4 cyl. 90 x 120	6,408	12,197
11—Peugeot	4 cyl. 90 x 120	5,485	10,634
12—Peugeot	4 cyl. 90 x 120	5,462	10,632
9—Front-drive Latil	2 cyl. 105 x 140	5,478	10.332
10—Front-drive Latil	2 cyl. 105 x 140	5,480	10,152
16—Delahaye	2 cyl. 100 x 160	4,695	9,298
17—Delahaye	2 cyl. 100 x 160	4,703	8,201
20—Panhard-Levassor	4 cyl. 81 x 120	6,399	13,323
21—Panhard-Levassor	4 cyl. 81 x 120	6,603	12.336
24—Berliet	4 cyl. 100 x 140	5,998	11,825
25—Berliet	4 cyl. 100 x 140	6,026	11,840
30—Vinot-Deguingand	4 cyl. 95 x 130	5,220	11,009
31—Vinot-Deguingand	4 cyl. 95 x 130	5,791	10,854

Benz, Not Mack, Gets Truck Trophy

On page 339 of The Automobile of August 25 it was said that "Mack Wins in Its Class." The information received by The Automobile at the time was to the effect that the Mack truck was slightly in the lead. It now transpires that the Benz truck was the winner, the figures being as follows:

COST PER TON MILE AS FIGURED BY THE COMMITTEE

Car No. 72, Benz	$ .00736
Car No. 73, Mack	.00738



Another one of Berliet's heavy trucks

The Peugeot and Delahaye trucks on the road

Malicet-et-Blin truck being weighed on the scale at Meulan

Doings in the East

NEW JERSEY AUTOMOBILE CLUB ACTIVE; CONTEST BOARD MAKING RULINGS; LANCASTER CLUB LOOKING AFTER ROAD WORK; QUITE A NUMBER OF NEW FACTORIES

—The Weed Chain Tire Grip Company announces that it will reduce the price of Weed chains to-day.

—The Automobile Accessories Company, William B. Yoder, president, has secured the Pittsburg agency for the Shawmut tires.

—George Sill Leonard, for some years with the Boston branch of the Studebaker company, is now with the Peerless company in the Hub.

—The Banker Wind Shield Company of Pittsburg is now fairly located in its new factory at Ellsworth avenue and Summerlea streets, East End.

—W. R. Cole & Son, of Oil City, Pa., have secured the agency for the Middleby automobile in Jefferson, Clarion, Armstrong, Clearfield and Indiana Counties, Pa.

—So complete has been the satisfaction given by Stearns taxicabs in Buffalo that the Buffalo Taxicab Company has just placed an order for seven more cars.

—William F. Lehman, veteran salesman in the automobile trade of Philadelphia, has joined the sales force of the Philadelphia branch of the Maxwell-Briscoe Company.

—Samuel Creese & Son, of Beaver Falls, Pa., have bought property on Seventh avenue in that place and will build a large automobile garage and repair shop at once.

—After losing nine horses, the Troy Laundry Co., of 172 Main St., Poughkeepsie, has purchased a gasoline delivery wagon from the International Harvester Co.

—The feature of the recent encampment of the N. G. P. at Gettysburg, Pa., was the use of a monster three-ton Packard motor truck for carrying the equipment and supplies.

—J. C. Howell has resigned his position as assistant manager of the Warner Instrument Company, to become advertising manager for Reed & Barton Company, at Taunton, Mass.

—Montgomery Hallowell, for several years connected with Lord & Thomas in New York, has been appointed general advertising manager of the United States Motor Company.

—The Franklin Motor Car Company, of 152 North Broad street, has contracted with the Cole Motor Car Company for the Philadelphia and vicinity selling rights of the Cole "30."

—The Whitten-Gilmore Company of Boston has added another former Studebaker man to its sales staff in Fred W. Nichols who has been selling motor cars in the Hub for some years.

—The Inter-State branch, that was opened in Boston this week, is located at 153 Boylston street, with Virgil A. Charles in charge. The entire New England business will be directed from there.

—A. J. Beckert, who was for several years connected with the firm of L. Glesenkamp Sons & Company, is now sales agent for the Willoughby Company and has his offices at Forbes Field, Pittsburg.

—The Stewart & Clark Manufacturing Company, makers of the Stewart speedometer, will open a sales office in Philadelphia. They are now negotiating for a very handsome salesroom on Broad street.

—Lucian Clawson and Elmer Turner, formerly of the Greensburg Auto Company, and Harvey Shoup are having plans drawn for a three-story garage in Maple avenue, Greensburg, Pa., to cost $20,000.

—The Castle Square Garage Company of Boston has taken on the Great Western for New England with headquarters on Ferdinand street. Subagencies will be placed in other New England cities.

—The Pittsburgh Automobile Dealers' Association is backing the movement to secure a new South Side tunnel which will give access to more than 100,000 people back of the Monongahela River hills.

—The Liberty Automobile Company, of Pittsburg, which was partly burned out recently, is now located at 5977 Centre avenue, East End. The company has recently taken the agency for the Abbott-Detroit car.

—Walter F. Winchester has severed his connection with the Pierce-Arrow Motor Car Co. of Buffalo, and hereafter will be head of the Winchester Motor Car Co., dealers in Pierce-Arrow cars, at Jacksonville, Fla.

—The location of the Stearns agency in Seattle has been moved from Fifth and University Streets to Broadway and Madison. The garage and salesrooms will be used exclusively in the interest of the Stearns in Seattle.

—H. C. & C. D. Castle has been merged into the Lozier Sales Company, of Boston, which will handle Lozier cars in the eastern half of Massachusetts. H. C. Castle, of the old firm, is president of the new Lozier Sales Company.

—Stillman & Hoag, Englewood, N. J., will continue handling the Locomobile and White gas cars during the coming season of 1911 and have taken the Chalmers-Detroit to replace the Buick line, which they have been handling.

—C. G. Norris, an English engineer is now in this country with two or three very interesting engineering novelties, one of which is the new type of wheel which has been adopted by the London Omnibus Company for its motor 'buses.

—The Consolidated Rubber Tire Company, manufacturers of the Kelly-Springfield tires, 315 North Broad street, Philadelphia, will shortly remove to 208 North Broad street. The floor space of the new quarters is nearly double that of the old.

—The city of Pittsburg will shortly build a model garage for housing its vehicles. It will hold the downtown fuel wagon of the fire department, the motorcycles of the police bureau and the city detectives' automobiles, and will cost $9,000.

—Vice-President and General Sales Manager of the United States Motor Company has announced that the Alden Sampson Manufacturing Company will build, in addition to its line of heavy commercial vehicles, a 1000-pound delivery wagon.

—Members of the New Jersey Automobile and Motor Club will take part in a sociability run Saturday, Sept. 10. It is expected that in the neighborhood of 100 cars will be in line, for the run is the first of the kind arranged for this season. The route the party will take will be from the city clubhouse in Park Place to the country club at Lake Apshawa, near Butler. On arrival there a clambake and corn roast will be the order.

—Vice-President Horace DeLisser, of the United States Motor Company, makes the announcement that that organization will hereafter be represented in all big racing and endurance events. Contest Manager M. C. Reeves will be in charge of the racing team.

—The Automobile Association of Indiana County, Pa., is prosecuting all road supervisors who do not comply with the laws for the betterment of country roads and its committee is making weekly trips over the five inspection districts to gather data.

—The first annual reliability run of the Automobile Club of Buffalo will start September 7 and will be concluded September 10. Both start and finish each day of the run will be from the club house on Main street and the course for each day will measure about 200 miles.

—Glenn H. Curtiss, the noted aviator, although completely absorbed in his work in which he has become a leader, recently purchased an Oakland runabout from the factory's representative, the Pittsburg Automobile Company.

—E. R. Mertens, superintendent of the Columbia Motor Car Company, has had ten cars of the 1911 model on the road in test. The new Columbia, which is of higher power than the 1911 car, is said to be very efficient. It has been demonstrated to be a hill climber and much is expected of it.

—The Howard Auto Transportation Company has been organized to conduct a passenger and freight service in Howard county, Maryland, within thirty days. The incorporators are Albert Nichols, Samuel A. Nichols, Samuel H. Hopkins, Covington Zepp and Stuart M. Bailey, all of Howard county.

—During the eleven months commencing August 1, 1909, and ending June 30, 1910, rubber was imported into this country to the extent of 96,000,000 pounds. This shows an increase of 13,000,000 pounds over the corresponding period preceding and over 24,000,000 pounds more than the same length of time in 1906-07.

—The National Automobile Company, capital $100,000, has been organized in Pittsburg and will take over the location formerly occupied by the Standard Automobile Company at 5917 Baum street. M. J. Caton is president of the new company, which will have the agency for the Owen and Haynes automobiles.

—The Hazard Motor Manufacturing Company, of Rochester, N. Y., has been incorporated, with a capital stock of $400,000, to take over the former Hazard Engineering Company. The officers of the new company are: E. C. Hazard, president; John F. Alden, vice-president; George R. Coates, treasurer; Willett E. Hazard, secretary; George E. Hazard, works manager.

—W. S. Drummond, organizer and former president of the New York Transportation Company, who is now engaged in the banking business in London and Paris, is in this country negotiating for the French rights to the Twombly automobile system and quick-removable power plant, which attracted so much attention from the trade experts when it was exhibited at the Automobile Club of America a few weeks ago.

—The Automobile Legal Association, of Boston, has been notified that Attorney-General O'Malley, of New York State, had rendered an opinion that motor cars bearing registrations of Massachusetts, Connecticut and Vermont did not come under the reciprocity clause of the New York law and therefore motorists from those States would have to register their cars to operate in the Empire State.

—The Matheson Automobile Company has just closed contracts with the following concerns: M. M. Gillett, Smethport. Pa.; W. King Smith Company, Syracuse, N. Y.; L. G. Everist & Son, Sioux City, Iowa; J. R. Todd, New Orleans, La.; Ideal Motor Car Company, Harrisburg, Pa.; J. M. Lopez, Biloxi, Miss.; J. K. Gilchrist Company, 123 East Seventh street, Cincinnati, Ohio.

—The S. M. Supplies Company, which has the Boston agency for the Inter-State and Brush cars for a year or more, has decided to drop its affiliation with the motor industry because of a press of other business. Victor M. Charles, manager of the agencies, will probably take charge of the Inter-State branch that is to be opened in Boston. It is expected that the Brush will also be handled as a branch through the U. S. Motors Company.

—The Collins Gear & Motor Company, of Pittsburg, has secured a location at Canonsburg, Pa., and will let contracts for a plant 60 x 300 feet at once. The company has a capital of $250,000 and will manufacture an appliance for automobiles invented by D. P. Collins at Pittsburg. Its officers are: President, J. J. Flannery; vice-president, D. P. Collins; treasurer, H. A. Neeb; secretary, J. M. Flannery. The offices of the company are at present at 324 Frick Bldg., Pittsburg.

—A four-cylinder 40-horsepower Pope-Hartford combination ladder and chemical wagon has been installed in Mansfield, Mass., for the fire department. The wagon cost $4,500 and is a thoroughly modern machine capable of carrying ten firemen and giving a speed of 35 miles an hour. It is equipped with a 40-gallon chemical tank and engine; one 20-ft. extension ladder; a 12-ft. ladder; two 3-gallon extinguishers; 1,000 feet of regulation fire hose; 200 feet of ordinary hose; axes, ropes and other things needed at fires.

—The C. W. Kelsey Manufacturing Company, of Hartford, Conn., has its first car on the road. It is called the Spartan and is a four-cylinder motor, three speeds, selective shaft drive, vestibule body and will seat four passengers. The car is to sell for $1,000, which includes lamp equipment, magneto and horn. C. W. Kelsey, president and general manager of the company, was formerly connected with the Maxwell-Briscoe Company as sales manager and recently resigned from a similar position with the Columbia Motor Car Company.

—The Boston *American* plans to have a contest for commercial vehicles on Oct. 14 and 15 starting from Boston and going to Newburyport the first day by way of Haverhill, Lowell and Lawrence, and the second day returning to Boston through Salem, Lynn, Beverly, Chelsea and Cambridge. It will cover about 130 miles and will be patterned after the Philadelphia *North American* contest from Philadelphia to Atlantic City recently. The machines will be divided into four classes of from 1000 pounds to anything over three tons, gasoline or electric. Officials of the Bay State A. A. will conduct it.

Middle West News

LOZIER CONCENTRATING AT DETROIT; INDIANAPOLIS SPEEDWAY BEING PUT TO WORK; PREMIER PLANT GETTING A TOUCH OF IMPROVEMENT; AGENCIES BEING ESTABLISHED

—R. L. Griggs will open a large garage to-day in Virginia, Minn.

—The number of automobiles in use in St. Louis has exactly doubled within eight months.

—The agency of St. Louis and territory for Continental automobile tires has been transferred to the Phoenix Auto Supply Company.

—The Anderson Carriage Co. of Detroit has opened a branch in Cleveland at Steeres' garage, 10550 Euclid avenue, with G. H. Rempes in charge.

—A. I. Dutton, Publicity Director of the Willys-Overland Company, has resigned to become sales manager of a prominent Chicago concern.

—A broad highway sixty miles long between Toledo and Detroit, traversing one of the most beautiful regions in the world, now seems a probability.

—Plans have been accepted for the $15,000 clubhouse which will be built by the Milwaukee Automobile Club, and the work of erection will start at once.

—T. L. Hausmann, late with the New York-Chalmers Company, has been appointed manager of the St. Louis branch, and is busy getting his sales force together.

—The Regal Motor Car Co. is soon to open a branch in Cleveland. A building has been leased for the purpose at 1926 Euclid avenue. Frank L. Pierce, formerly of the Gaeth Motor Car Co., will be in charge.

—A. A. Franklin & Company have been appointed factory distributors of the Cole "30" for Missouri. The company has offices and salesrooms at 4127 Olive street, St. Louis.

—A. R. Davis, manager of the Cleveland Studebaker Co., has been made a member of the Question Club, which is an exclusive club among automobile manufacturers and owners.

—The Scioto Auto Car Company of Chillicothe, Ohio, was incorporated with a capital of $150,000 to manufacture automobiles and motor trucks. The incorporators are F. C. Arbenz and others.

—The M. M. Baker Company, of Peoria, Ill., has leased a building at 2007-9 Locust street, for the establishment of a St. Louis house from which will be handled the Stoddard-Dayton and Courier cars.

—The Fayette County (Iowa) Automobile Association has just been formed, with the following officers: President, H. P. Hancock, West Union; Secretary, M. O. Musser, West Union; Treasurer, C. W. Bopp, Hawkeye.

—John G. Perrin, general superintendent of the Lozier factories at Plattsburg and Detroit, has just returned from an extended European trip taken for the purpose of studying the automobile trade and manufacturing conditions in general.

—H. W. Meyer, formerly of the Zimmerman Manufacturing Co. of Auburn, Ind., and more recently the Decatur Motor Car Co., of Decatur, Ind., is now general manager of the Planhard Manufacturing Co., carbureter manufacturers of Kokomo, Ind.

—The Standard Auto Sales Company has secured the lease of the first floor of the K. of C. Building in South Hazel street, Youngstown, Ohio, and will shortly move its garage, salesroom and repair shop there from its present quarters on West Rayen street.

—The Phillips Automobile Company has secured the agency of the Hudson Motor Car Company in St. Louis, formerly held by the Park Automobile Company. In addition to the Hudson, the Phillips Automobile Company will handle the Babcock Electric.

—The third annual good roads convention of the National Grange, Farmers' Union, American Road Builders' Association, U. S. Office of Public Roads, the National Association of Automobile Manufacturers and other organizations will be held October 6 to 8 at St. Louis.

—The *Tribune* Reliability run to Aberdeen, S. D., will start from Minneapolis either on Friday, Sept. 16, or two weeks later. It will last five days outgoing, one day at the Aberdeen control and two days returning, reaching Minneapolis on the night of the following Tuesday.

—Frank J. Santry, who has been for the last two years with C. C. Bleasdale in the Maxwell agency in Cleveland, has resigned and has accepted a position with Morgan & Williams, of Warren, Ohio, distributers in that section for Maxwell, Oakland, Overland, Oldsmobile and Columbia cars.

—E. B. Tozier of the Diamond Tire Company is having erected on Race street, just south of Ninth, in Cincinnati, a building of unusual architectural beauty. The structure is 24 x 120 feet, two stories and basement, and is to be occupied as salesroom and offices by the Diamond Tire Company.

—The Hitchcock Motor Company of Warren, Ohio, has been organized. M. H. Hood of West Farmington, Ohio, has bought the interest of J. H. Hitchcock and will be the president of the company. E. W. Skinner, for the past three years manager of the Bangora Slate Company at Columbus, Ohio, has bought the interest of R. H. Crehan and will devote his time to the company.

—The Henderson Sales Company of Indianapolis has selected Atlanta for its Southern headquarters, and will distribute from that city in the following States: North Carolina, South Carolina, Virginia, Tennessee, Georgia, Florida and Alabama. The local branch will be located at 76 Peachtree street and will be in charge of Leonard Cater.

—C. B. Warren has returned to the Haynes Automobile Co of Kokomo, Ind., resuming his old position of salesmanager. Mr. Warren left the Haynes Company in 1908 to represent the Stearns Automobile Co. on the Pacific coast, and later went into the retail business in St. Paul, Minn., with Burney Bird who represents the Haynes Co. in the Twin Cities.

—Mr. N. H. Miniter, formerly general factory representative of the Schebler carbureter and for the past year sales manager of the Eisemann Magneto Company, has been appointed sales manager of the Reichenbach Laboratories Company, manufacturers of the "Vortex Vaporizer." Mr. Miniter will make his headquarters at the home office of the company, 2420 Michigan avenue, Chicago.

—The seventh annual outing of the Milwaukee Automobile Club to the orphans of Milwaukee was a big success this year. The ride was to and from Washington Park, where the festivities were held. There were 101 orphans from the St. Rose's asylum, 90 from the Milwaukee Protestant Orphan asylum and many from the St. Aemilianus asylum, more than 200 in all, and each boy and girl was taken home at night an enthusiastic motorist.

—A record was established recently by a two-ton United States Motor truck on a three days' run from Cincinnati to Chicago. The distance of 361.4 miles was covered in about 26 hours and 15 minutes. Twenty-six gallons of gasoline and two and one-half gallons of oil were consumed on the trip. The demonstration was made by Norman S. Hill, sales manager of the United States Motor Truck Company of Cincinnati, and E. C. Schumard, general superintendent of the same company.

—According to advices from the course, the winning Lozier car in the Elgin National Trophy race was equipped with Michelin tires as were also the National that finished second in that contest and the one that got third money. In the Illinois Trophy race the winner, a National; Falcar, second and Marmon, third, ran on Michelin tires. The winning Marmon in the Kane County Trophy race as well as the Marion which finished second and the Marmon that was third were all similarly equipped.

—At the annual meeting of the Firestone Tire & Rubber Company, held in Akron, August 24, the former board of directors was retained and the following officers were re-elected for the coming year: H. S. Firestone, president and general manager; Will Christy, vice-president; S. G. Carkhuff, secretary and J. G. Robertson, treasurer. It was announced that the new model tire plant now in process of construction will be completed by February, increasing the manufacturing capacity fourfold.

—The Stover Motor Car Company of Cincinnati was incorporated with an authorized capital stock of $25,000 to manufacture and sell motor cars and other vehicles by L. K. Emerson, George W. Platt, R. L. Dallings, Stanly M. Adams, Parker K. Gale and Alex. L. Parker. The American Auto Sales Company of Cleveland was incorporated with an authorized capital stock of $50,000 to do a general automobile and repair business by George H. Canniff, John K. Corwin, E. P. Kinney, W. W. Welch and Frederick P. Walters.

—The Milwaukee Automobile Club will furnish the automobile to make the five-mile race with an aeroplane at the State fair here September 13-17. Indications are that the Milwaukee Automobile Club will inaugurate with a motor parade the opening day of the Wisconsin State fair and with this end in view has asked that, if possible, the new Grand avenue viaduct, one of the largest concrete bridge structures in the world, may be completed for traffic during State fair week. Plans are to have the viaduct used for the first time by the parade.

—The Louisville Automobile Club's second annual reliability and economy contest will be held September 20, 21 and 22 and two of the cars which participated in the 1910 Glidden tour will probably enter. The Cole car and a Premier will likely be named. Entries have been received and several numbers have already been assigned. The tour this year will cover about 500 miles through the Bluegrass. Three silver loving cups are offered this year—one for economy, another for the best reliability score and the third prize is called the owner's cup.

From the Sunny South

THE PRESENT MONTH WILL SEE NASHVILLE THE HOME OF THE ONLY AUTOMOBILE FACTORY BELOW MASON & DIXON'S LINE—GENERAL TRADE NEWS

—A charter has been granted the Jackson, Tenn., Garage Company of Nashville, Tenn. The capital stock is $10,000 and the incorporators are: Chas. E. Dexter, F. M. Spiller, Mark Glen, and J. A. Pope.

—Amateur and professional automobile men of Texas, elated with the success which attended the recent meet on Galveston Beach, are beginning already to formulate plans for a more extensive meet next year.

—The Governor of Tennessee has announced the appointment of a large number of delegates to the Southern Appalachian Good Roads Convention to be held in Knoxville, Tenn., during the Appalachian Exposition at that place. The convention opens on Sept. 12.

—The Regal Company of Detroit has opened a Southern branch at 380 Peachtree street, Atlanta, under the name of the Southern Regal Auto Company of Georgia. This company will have Virginia, North and South Carolina, Georgia, Florida, Alabama, Mississippi, Louisiana, Arkansas and Tennessee as its territory.

—*The Exhaust* is the title of a new automobile journal, the first number of which will be issued on Sept. 5th. It will be published by the Exhaust Publishing Company, 204 Stahlman Building, Nashville, Tenn. Charles C. Gilbert, secretary of the Nashville Automobile Company, is the editor.

—The first Baltimore chauffeur to have his license suspended for using his owner's car without the latter's consent is Frank T. Trainor. The action was taken by Motor Vehicle Commissioner John E. George under the new Swann Motor Vehicle Law. The owner and the Automobile Club of Maryland, through the club's counsel, Osborne I. Yellott, prosecuted the case.

—The city of Nashville, beginning to-day, will oil all new streets that are built and all old ones that are repaired, expecting in this way to ultimately get most of the streets of the city oiled, excepting of course the uptown paved streets. Rock is abundant at Nashville and all of the streets are well built, but unfortunately the rock is soft limestone, wears rapidly and makes a tremendous amount of fine dust, so much so that it is necessary to sprinkle all of the streets of the city daily.

—By the middle of September the Southern Motor Works, said to be the only automobile manufactory in the South, will be turning out Marathon cars from its Nashville plant at the rate of five per day, according to plans. The plant has really been running for several weeks, but all of the equipment has not yet been placed in position. About 75 men are now employed, but the force is to be rapidly augmented until it reaches 400. The plant is located in a big brick structure that was formerly a cotton factory and with some remodeling has made a very desirable place for its present purpose. The plant was formerly located at Jackson, Tenn., but was removed to Nashville, the capital largely increased and operations greatly enlarged. Only two models were turned out at Jackson, but the Nashville factory will begin with four, roadsters, touring cars, as per the old patterns, and the same with torpedo body. C. H. DeZevallos will have charge of the uptown agency.

Across the Great Divide

FRANKLIN SMASHES COAST RECORDS; FRISCO GETS NEW AGENCIES; PORTLAND IS AWAKENING TO MANUFACTURING; ALAMEDA ESTABLISHING AUTO SERVICE

—The Pacific Motor Car Company, of San Francisco, has just taken over the agency for the Reo car.

—The Cole Motor Car Company will establish a branch house at San Francisco. F. W. Cole, Jr., will be in charge as manager.

—The Glenn County Garage, at Willows, Cal., has taken the agency in that district for the Studebaker, E-M-F and Flanders cars

—The Morrison-Cole Motor Car Company, which it is now officially announced will handle the Cadillac in San Francisco, has been recently organized for that purpose.

—Rene J. Marx, manager of the Pacific Coast branch of Renault Frères, announces that the Renault car has been taken over by the Portland Taxicab Company.

—Max L. Rosenfeld, San Francisco agent for the Apperson car, has leased the stores formerly occupied by the Pullman and Dorris agencies on Golden Gate avenue.

—The city of Alameda, Cal., has just put in commission a Pope-Hartford combined police patrol and ambulance. It is a 50-horsepower machine and will accommodate twelve persons.

—The E. S. DeTamble Company will be exclusive Pacific coast distributers for the DeTamble line of cars covering all territory west of Denver, including the Republic of Mexico.

—The Middleton Motor Car Company has been incorporated in San Francisco, with a capital stock of $50,000, by W. H. Middleton, W. C. Crittenden, E. P. Cooper, S. B. Holman and C. C. Burr.

—C. F. Splitdorf, the well-known manufacturer of ignition specialties, has just opened a branch at 1226 South Olive Street, Los Angeles, Cal. P. M. Graves will have charge of the new branch.

—The Elmore car is to have a new home in San Francisco. A. J. Smith, the Pacific Coast distributer, has taken a five-year lease of a new permanent building which is to be erected on Golden Gate avenue, near Van Ness avenue.

—The Ajax Auto Traction Company, of Portland, Ore., has let contracts for the construction of a large manufacturing plant, and has ordered a complete machine shop equipment. The company is capitalized at $500,000, and is backed by a number of prominent Oregon business men.

—The Monitor Automobile Works, 206 N. Academy St., Janesville, Wis., formerly of Chicago, has just opened a Los Angeles agency with the C. G. Dwight Auto Co. This concern is one of the best known in Los Angeles and will push the Monitor commercial car among the merchants of that city.

—Two record-breaking performances marked the recent trip of a score of air-cooled Franklin cars from Portland, Ore., to the Government camp on Mount Hood. A one-ton truck of 18-horsepower made the climb carrying 2,600 pounds of dead weight, and G. L. Campbell drove his six-cylinder 48-horsepower car, carrying seven persons up to the camp, 50 miles, in two hours, consuming but 12 gallons of gasoline.

Prominent Automobile Accessories

USEFUL EMERGENCY WHEEL

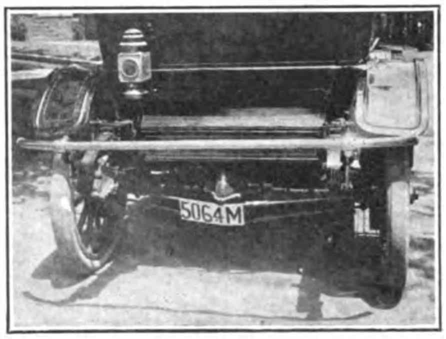
Time lost by reason of tire trouble is frequently a big factor to the autoist, and any device which can save him a quarter of an hour or more—with its consequent fuming and fretting—is not to be ignored. Such a device is the Jenkins emergency wheel, made by the factory of the same name in Richmond, Va. As the primary consideration, ease and quickness of application have naturally been first considered in this wheel, although the element of strength has not been overlooked in its make-up. It will fit any make of wheel or rim.

A quick-action hand pump

Six steel plates firmly fastened to the emergency rim form seats upon which the rim of the regular car wheel rests when it is in place. The emergency wheel is held in place against the side of the car wheel by three steel arms, which reach through the inside of the car wheel and engage the inner edge of the rim. The simple tightening of the three bolts on the outside of these three arms holds the emergency wheel fast to the car wheel, forming a strong positive support that cannot give way.

The regular car wheel cannot be harmed by the emergency wheel, for when the latter is in place no part of it comes in contact with the injured wheel. Steering is not interfered with when the substitute has once been firmly placed, and any car so equipped may be driven a hundred miles or more without trouble.

In Fig. 1 is shown the left front wheel with its *hors de combat* tire jacked from the ground and the operator loosening the nuts on the three steel arms which reach through the car wheel and engage the inner edge of the rim. Fig. 2 shows the operator placing the emergency wheel on the outside of the car wheel that is out of commission, and turning the arms so that they will engage the inner edge of the rim of the latter. In Fig. 3 the operator is tightening up the nuts at the outside end of the three steel arms, after which he is ready to proceed. The whole operation consumes but very little time—experts have been said to perform it in considerably less than a minute.



Rear fender to save tail lamp, fenders, gasoline tank and body

SAVES ROOM AND DOES THE WORK

The combination-filter, measure and funnel here shown is a very compact and handy item in a car's outfit. It is made by Charles R. Gibson, of Salamanca, N. Y. Just above the handle is a spring lever, pressure upon which opens the funnel and allows the oil to run through the filter after the proper amount has been measured.

EASY-ACTION, POWERFUL HAND PUMP

Inflating tires by hand is such an exhausting procedure that the motorist whose car is not equipped with one of the mechanical pumps should see to it that the hand pump he carries is powerful and easy-working. The Myers Airtite, manufactured by the Keystone Novelty Company of Columbia, Pa., possesses merit along these lines that should recommend it to the autoist. With no leather parts and with metal piston and expansion rings like those in the cylinder of an engine, it is positively air-tight, and being made throughout of brass, steel and iron, it will outlast many of the ordinary pumps.

Measure, funnel and filter in one

REAR FENDERS FOR AUTOMOBILES

Automobiles, used in the larger cities, that are not equipped with fenders are as difficult to find as the proverbial needle that got in the way of the hay stack. In thus equipping their cars, owners have mechanically followed the custom of attaching a fender only to the front of the car. Automobile mechanics have for some time sought to provide some adequate means for protecting the rear axle, gasoline tank, tail lamp, body and fender. It would seem that their problem is solved by the simple expedient of attaching a bumper to the rear spring hangers.

The accompanying illustration shows that a Detroit motorist has seen the utility of this idea and has attached a "Swivel-action" bumper to the rear of his car. These fenders are being marketed by the Emil Grossman Company, 232 West 58th street, New York City.

Fig. 1—First operation in adjusting Jenkins Emergency Wheel

Fig. 2—Second operation, fitting emergency wheel in place

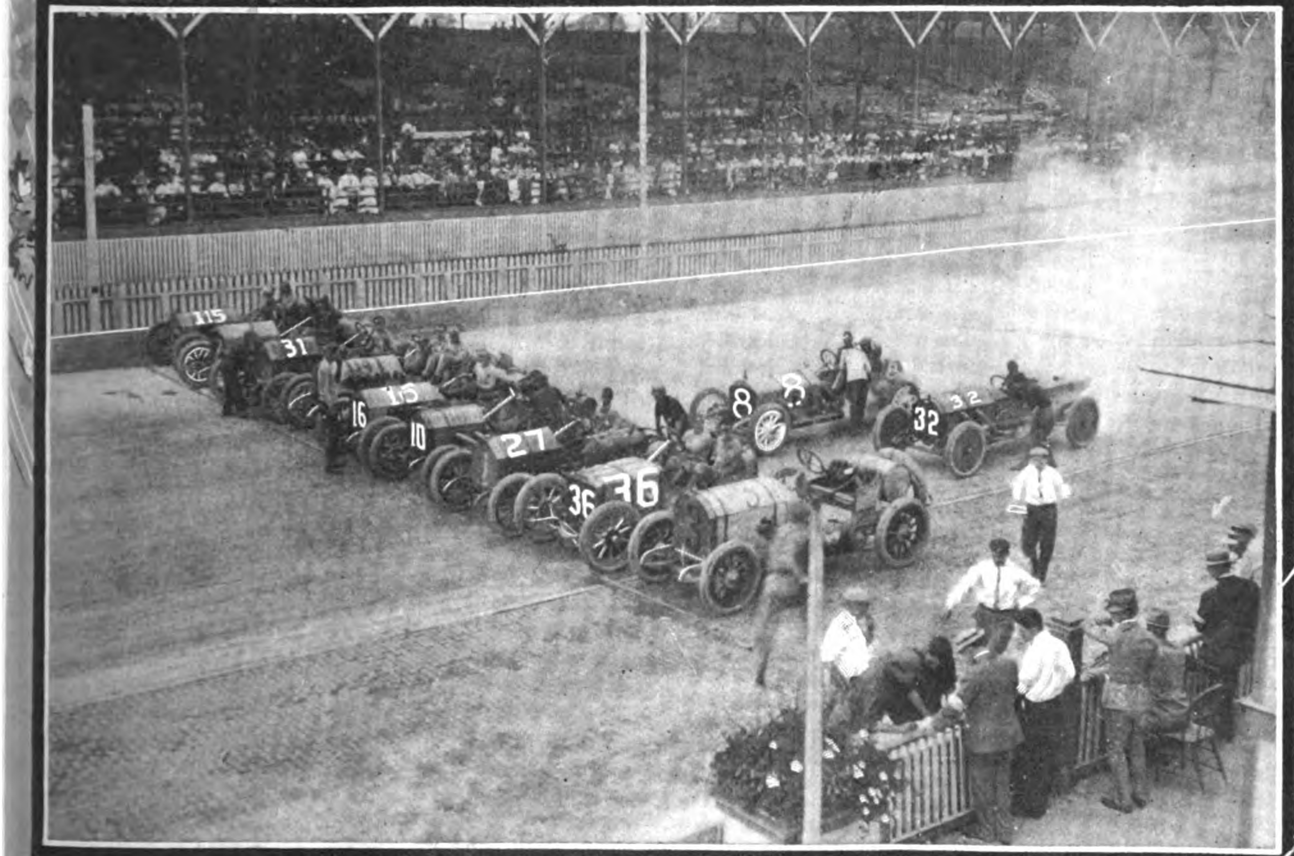
VOL. XXIII NEW YORK—THURSDAY, SEPTEMBER 8, 1910—CHICAGO No. 10

THE AUTOMOBILE

Labor Day Events at Indianapolis

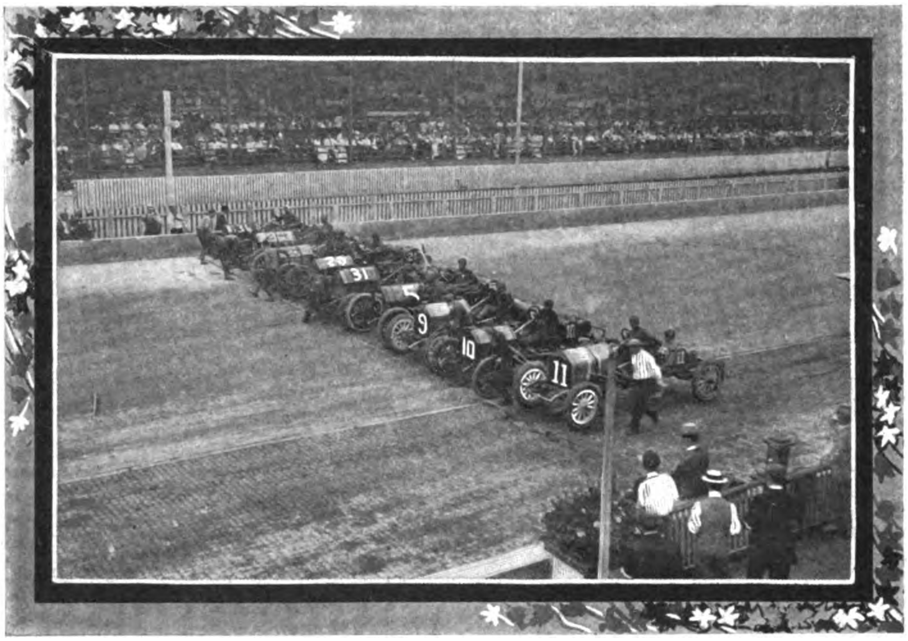


INDIANAPOLIS, IND., Sept. 3—Although no records were broken in the first day's races of the two-day meet which marked the closing of motor car competition at the Indianapolis Speedway for the season of 1910, considerable interest was shown and some remarkable performances were made in the two 100-mile events in which the Benz and one of the Nationals were the shining lights.

The 100-mile free-for-all was won by Hearne in the big 200-horsepower Benz. The prizes in this event are $1,000 to the winner, $500 for second place, $200 for third and $100 for fourth. This event brought to light a dark horse—a new Indiana car, the Westcott, burst into the limelight by showing its heels to a classy field and finished second to the big Benz. The Benz's time for this event was 1 hour 19 minutes and 58.1 seconds, which is 25.1 seconds slower than the Marmon's National Speedway record. The Westcott crossed the tape 4 minutes behind the winning Benz, and National, No. 7, was third.

There were 11 starters in the Remy Grand Brassard event and the six cars that finished made non-stop runs. National No. 9 was first in this event with National No. 11 second, Speedwell third, Midland fourth, Black Crow fifth, McFarlan sixth.

In the time trials the nearest that the 200-horsepower Fiat could come to the record



Start of the Remy Brassard—National, Marmon, National, Speedwell, Firestone-Columbus, Black Crow, Midland, McFarlan, Cino

was a mile in 38:64 and 40:20 in the 90 horsepower machine of the same make. In event No. 2, a race between three Herreshoffs, Emmons was first and Smith second. The Cole 30 was winner of the third event, with the Staver and another Cole close contenders for second place. Marmon No. 26 won the laurels in event No. 4, but was close pressed by Falcar No. 15, while Falcar No. 16 was third. In the fifth event National No. 9 was the shining light with Marmon No. 10 second and National No. 18 third. National No. 9 was the bright star in the sixth event, second and third places going to National No. 18 and National No. 11, respectively. The Benz 120 made its first appearance in event No. 7, which it won easily, with National No. 7 second. Fiat No. 2 would have given the Benz a good run for the money in this race had it not been for stalling the motor at the tape at the start. The five-mile handicap event went to Cole No. 6, with the Matheson finishing second and the McFarlan third.

The Westcott's performance in the 100-mile free-for-all event is remarkable for the fact that not a single stop was made throughout the race. Driver Knight stopped for 24 seconds in the thirty-fourth lap to take on oil, and it is interesting to note that though he set the pace the entire distance his tires were in excellent condition at the end. Two stops were made by National No. 7, each of which consumed more than a minute and a half, the first being in the thirteenth lap on account of a blown-out right rear tire, and the second in the twenty-fifth lap for a right front tire and water. Similar tire trouble was encountered by Harroun, who was fourth, the changes being made in the eighteenth and thirty-fifth laps. Creditable performances were also made in this race by the little Falcars which had already competed in two previous events. Pierce lost about three minutes in the twenty-fifth lap repairing a broken ignition cable, and Galnow lost two minutes in the twelfth lap replacing a spark plug.

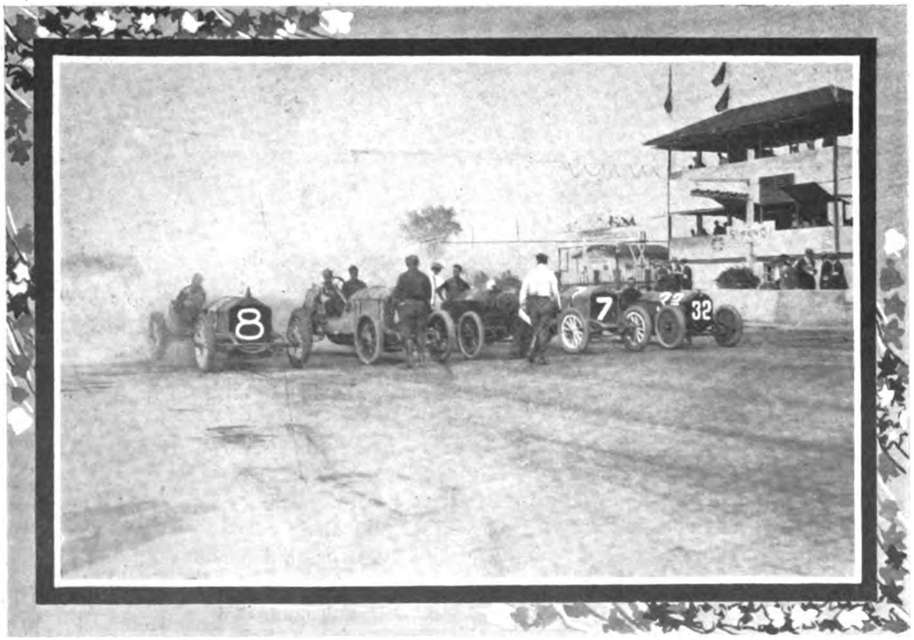
Joe Dawson in a Marmon, who drove the winner of this year's Cobe Trophy, led the field in the Remy Grand Brassard for many laps, and it was nip-and-tuck between him and National No. 9 until he suffered engine-bearing trouble and went out in the twenty-fifth lap. With the Marmon to the mat, the two Nationals had the race well in hand, though Clemens' Speedwell clung like a wolf on their trail until the very finish of the event.

Labor Day's Events

INDIANAPOLIS, Sept. 5—The powers that be were surely lenient to the crowds that thronged the Indianapolis Motor Speedway to witness the closing events of the season, for notwithstanding the fact that a heavy downpour of rain occurred shortly before the time for which the first event was scheduled, the weather soon cleared up and remained favorable throughout the afternoon leaving the track cool and in excellent condition, a fact which notably improved the wearing efficiency of the tires.

The 200-mile race for cars of 600 cubic inches piston displacement or less was the feature event of the day, and at 3:30 o'clock the twelve starters were sent away. The first prize in this race was $1,000, second $500 and third $200, and in addition to this the Bosch Magneto Company posted an extra $300 as a first prize, $200 for second and $100 for third. National No. 8 was the winner in this event with National No. 7 second, while McFarlan Six, No. 23, after getting first and fourth positions in two previous events and making the only non-stop run in the race, finished third. A threatening cloudburst so enveloped the track in darkness near the finish of this race that much difficulty was experienced by the starter and the timers in bringing it to a successful close. The race was continued, however, until a National No. 18 came in fourth. McFarlan No. 24 was on its last lap when the race was finished, while Black Crow No. 28 was also running on its seventy-eighth lap.

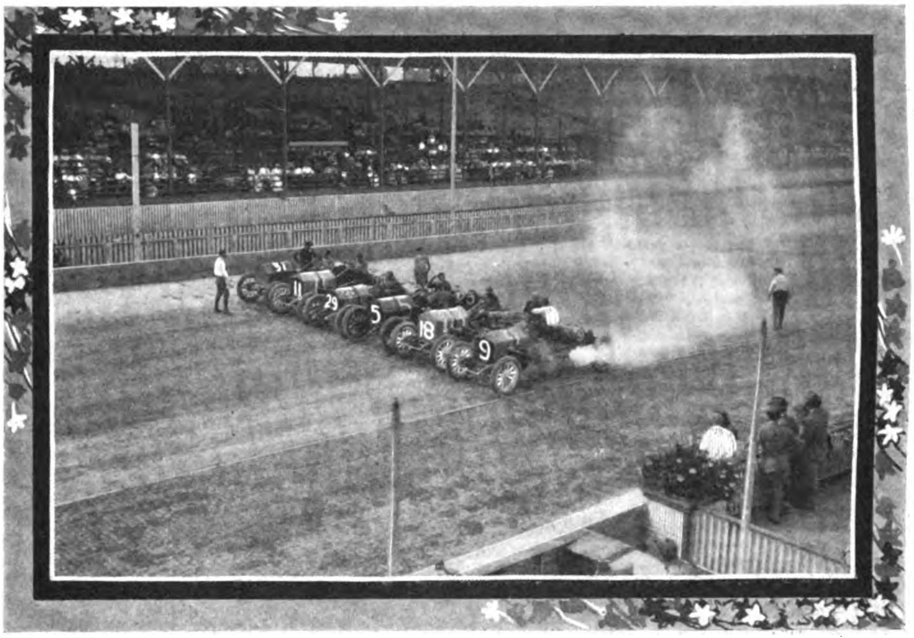
At 30 miles National No. 8, McFarlan No. 24 and Marmon No. 32 were fighting for the lead with the first named two lengths in front, while National No. 7



Line-up for the Class D, free-for-all—Marmon, National, Fiat, Benz, National and Marmon No. 10 were having it out for fourth position. This is rather remarkable because National No. 8 lost almost a minute in the fourteenth lap replacing a right front tire. At 40, 50 and 60 miles Marmon No. 32 was in the lead and although it was necessary for it to stop at the end of the twenty-ninth lap it succeeded in establishing a new record for the distance of 75 miles, the time being 1:03:31.9 the previous record of 1:09:34.6 being held by a National and made on this track. This stop of 2 minutes 15 seconds, in which Marmon No. 32 took on gasoline and oil and changed a right rear tire, set it behind considerably, but at 100 miles it was again but a hundredth of a second behind the leader. From here on, however, National No. 8 held the lead and Marmon No. 32 was running second at 170 miles, after which it dropped out.

One of the most interesting events of the day was the 50-mile free-for-all open race which was won by the big German Benz of 120 horsepower. The Benz ran away from a field of eight starters in this event and in doing so annexed three records. At 15 miles it smashed the Indianapolis speedway record of 12:32:04 by making the distance in 11:22:02. The Atlanta speedway record of 15:31:80 for 20 miles was reduced to 15:06:52; and at 25 miles the National's Indianapolis record of 21:21:07 was shattered and replaced by a new one of 18:56:84. Among the starters in this race were the 200-horsepower Fiat, National No. 7, National No. 8, Matheson No. 14, Westcott No. 27, Firestone-Columbus No. 31 and Marmon No. 32, the prizes being $800 for first place, $400 for second and $200 for third. At the end of 10 miles the Benz led, having passed the Fiat after the first lap. The latter was running a close second, however, with Marmon No. 32 well up in third place, while both Nationals were trailing a mile behind. The Benz also held the lead at 20 miles though closely pressed by Marmon No. 32. The Fiat began to lose time in the seventh lap when it was compelled to stop for a rear tire change. The Benz practically had things its own way at 30 miles, the Fiat and Marmon No. 32 both being compelled to run into their pits during the eleventh lap and change tires. These stops enabled National No. 7 to climb into second place, while Marmon No. 32 was running third and the Fiat fourth. The Benz was almost a lap to the good at 40 miles though Marmon No. 32 had regained second place and Livingstone was running third. The Fiat suffered tire trouble again in the sixteenth lap. At the end of the race the Benz was still almost a lap in the lead while Marmon No. 32 was second, National No. 7 third and the Fiat fourth.

In event No. 7, a free-for-all open race of 10 miles, there were six starters. This event went to the 200-horsepower Fiat, which got away in the lead and at the end of the first lap was almost a hundred yards ahead of its nearest rival, the Benz, and although the Fiat maintained the leading position till the finish of the race the end of each lap showed the Benz about 25 yards closer, and at the finish of the race, which was most exciting, the German car was less than a length behind. Third position in this event went to National No. 11. Of the ten events on the program this afternoon the rest were for 5-mile distances and each was confined to a different class of cars.



Start of the 301-450 race—National, National, Speedwell, Midland, National, Firestone-Columbus

FIRST DAY'S SUMMARIES

One mile—Time trials (Record 35.68)—

No.	Car	Driver	Time	
1	Fiat	De Palma	38.64	
2	Fiat	De Palma	40.20	
Five miles—160 cubic inches and less—				
			2½ Miles	5 Miles
19	Herreshoff	Emmons	3:21.22	6:20.48
21	Herreshoff	Smith	3:24.71	6:21.19
20	Herreshoff	McCormick	4:01.35	8:04.80
Five miles—161 to 230 cubic inches—				
6	Cole	Edmunds	2:31.28	5:05.50
17	Staver	Keifer	2:40.25	5:07.20
33	Cole	Endicott	2:51.21	5:07.79
35	Hudson		3:05.14	
Five miles—451 to 600 cubic inches—				
9	National	Wilcox	2:11.50	4:06.75
18	National	Greiner	2:12.31	4:07.51
11	National	Merz	2:16.57	4:18.10
14	Matheson	Basle	2:18.18	4:19.79

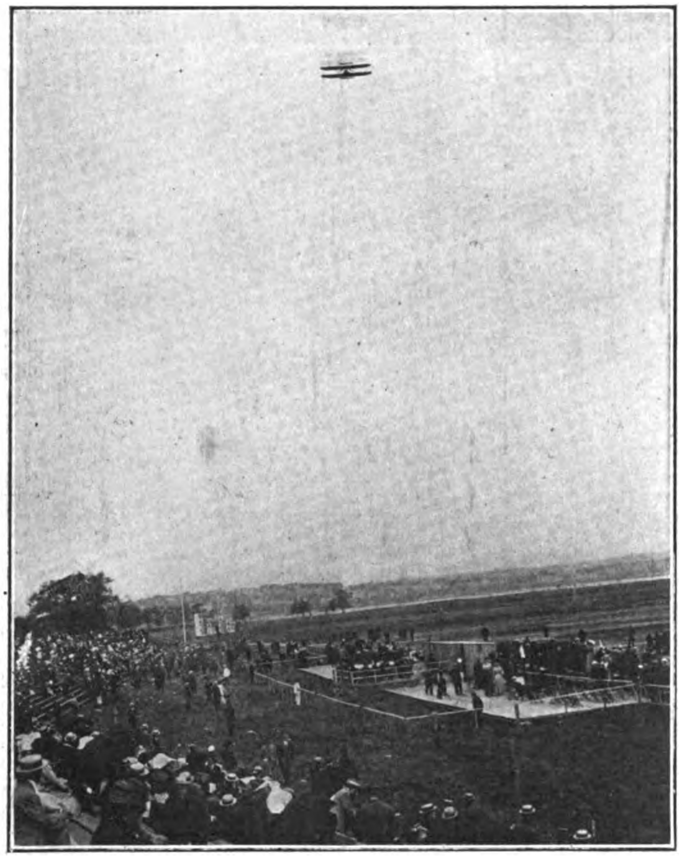
The 231-300 bunch under way—McFarlan, Falcar, Falcar, McFarlan, Parry, Marmon

Harvard-Boston Aero M

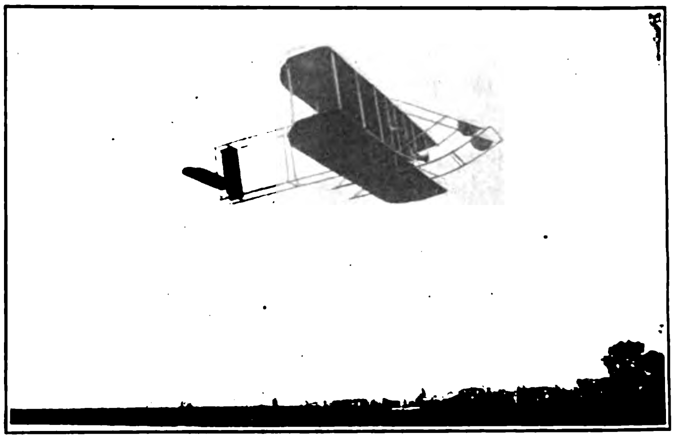


View of the ground and grandstand with Aviator Johnstone aloft in a Wright machine

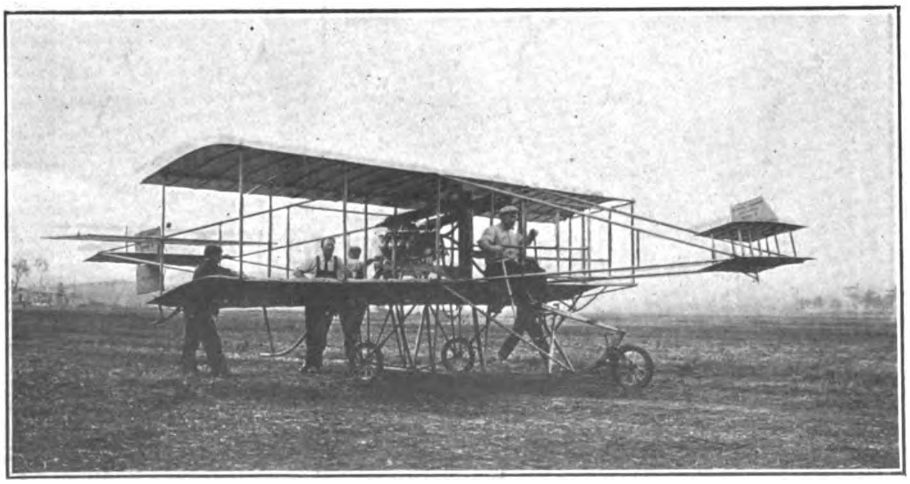
CAMPED in a salt marsh district known locally as Squantum and officially as Atlantic, Mass., the Harvard-Boston aviation meet was duly opened last Saturday to the accompaniment of a pattering rain and in the presence of a sea of umbrellas under which were heard the unflattering comments of Bostonians and strangers alike with regard to the poor provisions made for transporting a crowd of visitors to the flying grounds by rail or otherwise.

Among the aviators who had been billed to show the new art, the majority were mostly noted by their absence, but those who were there were the reliables whose ability to fly has been demonstrated over both sea and land, and, as in accordance with this fact, the aviation field stretched itself amphibiously from the grandstand toward the waters of Boston Bay, covering an uneven expanse of summer-dried marshland, studded with shallow tidal sinkholes and scalloped with patches of rank grass and sandy hummocks. The field in its soft unevenness offered a premium for machines and aviators capable of negotiating a quick getaway, at starting, whether by means of powerful motors or a friendly monorail starting device.

Claude Grahame-White, the noted English aviator who contested with Paulhan in the flight from London to Manchester, cut the impatience of spectators short as early as Friday, when many had congregated, by short decisive and rapid flights in his Blériot monoplane, not only inside the grounds but out over the ocean and making rises and swoops for the special delectation of the unpaid admissions grouped in the adjacent landscape, and on Saturday he was again the readiest starter and most willing exhibitor. Twenty yards of run in the tall grass was sufficient for sending his machine up, though the Gnome engine with which it is equipped is not of the 14-cylinder but the original 7-cylinder pattern. The most original wizard of aviation, Wilbur Wright, has been on the ground for several days and supervised the installation of quarters for his two fliers Ralph Johnstone and Walter Brookins, who took turns with the new "headless" biplane and a Wright biplane of the type shown many times before and practically the same which the Wrights had ready and tried out in 1905. Glenn H. Curtiss was present with the same machine which last Wednesday and Thursday he had flown from Cleveland to Sandusky and back again over Lake Erie, partly in a driving rain. It is of the rapid type, the planes having but slight curvature while the motor is of the eight-cylinder V-type and said to develop about 60 horsepower. Charles F. Willard had charge of another Curtiss machine, considerably smaller and provided with much more strongly curved planes and therefore better adapted for exhibition work but not for speed. A. V. Roe of England was ready with one of his triplanes, having two of these apparently cumbersome machines on the ground, but was handicapped in starting by the nature of the field, whose unevenness and softness were naturally unfavorable to the height and weight of his construction. Horace F. Kearney with a Pfitzner monoplane did not have good enough



The "headless" Wright flyer with rear elevating rudder

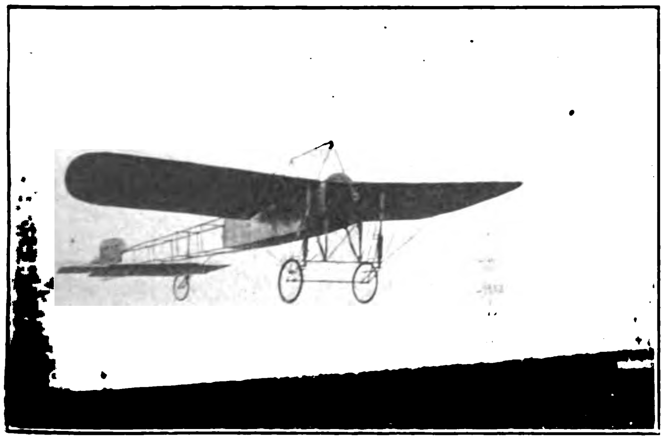


A Curtiss machine in which the ailerons have been moved back of main planes and with single elevating rudder

FLIERS OF ACKNOWLEDGED REPUTE BRAVE THE DIFFICULTIES OF A SOFT FIELD, RAIN, FOG AND OCEANWARD WINDS AT THE BIG AVIATION MEET

luck to get his machine ranked among the successful ones for the present. The indefatigable amateur Clifford B. Harmon was present with a Farman biplane provided with Gnome motor and a large gasoline tank, but suffered the misfortune of having his machine seriously wrecked in one of the first flights he undertook on the opening day. In trying to turn around one of the pylons or marking towers, before his machine had reached sufficient speed to permit this maneuver and only about fifty feet in the air, one end of his machine struck the ground, the aviator stating that the accident was due mostly to his own fault in judgment superinduced by the soft ground which interfered with his start, and by a gust of wind which caught underneath one side of the planes unexpectedly. While it had been this aviator's intention to go to St. Louis to give an exhibition, the accident changed this plan, and the machine was taken to the aeroplane factory of W. Stanley Burgess at Marblehead, Mass., for repairs.

A representative of the United States Navy was present to witness the bomb-throwing experiments for which arrangements had been made by placing an imitation man-of-war near the middle of the field and providing plaster of paris balls about 3 inches in diameter. From a height of 400 to 500 feet Grahame-White, carrying ten balls in a fisherman's creel beside his seat in the Blériot machine, succeeded in throwing one ball right into the central funnel rated as the bull's eye and another into one of the other smokestacks of the putative vessel, while most of the other balls hit near the vulnerable spots; and the naval representative shuddered at the destruction which would have been wrought.

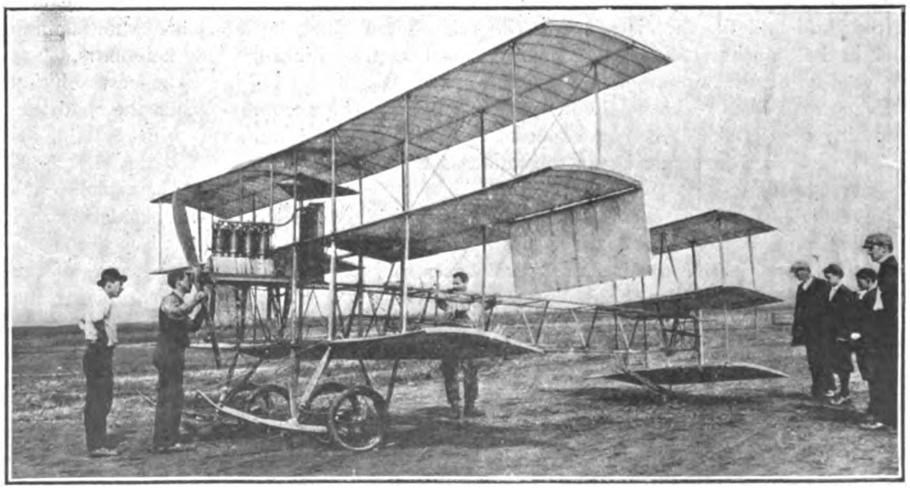


Grahame-White flying in his Blériot monoplane—the dummy man-of-war target for bomb-throwers to the extreme right

Sunday was officially a rest day, but a considerable number of visitors gained access to the ground and were rewarded by seeing Cromwell Dixon, a lad of sixteen and the youngest aeronaut of the age (though closely pressed by the aviator Marcel Hanriot, of France, a son of the well-known automobile racing man of the same name), attempt a flight with a small dirigble balloon and save himself from being carried out over the ocean only by the exercise of great presence of mind and a dexterity promising greater accomplishments in the future.

Start of a Farman machine which has been likened to "clothes on a line"

While all the aviators mentioned entertained the crowds worthily on Labor Day and Tuesday and made all the evolutions, swoops and dives in which the eye delights, no records were broken or created. On Tuesday a London fog made it impossible to see a machine more than 100 or 200 feet in any direction, including upward. The most interesting trials were those relating to the getaway or the length of the run on the ground required to make the machine rise. Grahame-White succeeded in rising with his Farman biplane, with a start of 66 feet, while the Curtiss machine required twice this distance. The big Curtiss flier is now equipped with "ailerons," or winglets, which extend to the rear of the main planes, so as to obtain a steering and balancing action which is not reduced and interfered with by having three planes.



Mr. Roe's triplane (British) which had difficulties in leaving the ground

New Body Creation

PRESENTING GENERAL WORKING DRAWINGS OF A NEW IDEA IN BODY WORK SHOWING ACCOMMODATION FOR A GUEST. DRAWN BY GEORGE J. MERCER FOR THE AUTOMOBILE.

THOUSANDS of autoists have learned by experience that a tonneau adds very materially to the cost of maintenance of a car, due to the fact that empty seats in the tonneau constitute an invitation for additions to the party, and the disagreeable feature is entirely beyond the fact as represented in a more or less apt quotation, *i e.*, "two is company and three is a crowd." It is almost impossible to evade taking the neighbors along; they suggest the idea every time they get a chance, not in so many words perhaps, but in a hundred ways both firm and convincing.

The added cost would not be a serious consideration were it confined merely to filling the tonneau occasionally, but it seems to be the misfortune of nearly every autoist to have to entertain guests every time the car is rolled out. The entertainment is in more ways than one, even the tire bill mounts up to enormous figures relatively, and one of the strange situations is portrayed in the fact that the owner of a car has to get down on his knees in the mud and fix the tires, while the self-invited guest lays back in the tonneau smoking the owner's perfectos, and criticising the quality of the automobile.

Every man likes to be neighborly; he is willing to be accommodating absolutely at his own expense, and self-sacrifice is not to be overlooked in summing up the qualities to be esteemed in the average man.

Nevertheless, it does seem as if neighbors quickly wear out their welcome, partly on account of their bad manners, to some extent in view of the large increase in expenses that attend their presence, and there is also the feeling that they think a man is as rich as Crœsus because he owns an automobile. There is small chance of accumulating even Crœsus' chicken-feed under the conditions represented by a tonneau and a perfectly willing set of neighbors.

This situation is much more serious than an outsider might realize. The pleasure that should attend the presence of a sweet running automobile is much dimmed, partly by the feeling that the owner has when he looks at the empty seats in his tonneau and encounters the longing gaze of his nearby friends. Then, there is the fellow who persists in coming along but who refuses every invitation to stop by the wayside for luncheon for fear he will have to pay the bill. It is bad enough to have one's enjoyment shattered by the presence of mixed company, but to be compelled to go without anything to eat for a whole day simply because the company has a tightwad in his makeup is past putting into good English.

There are two or three solutions to this problem, one of which is to have a family large enough to fill the tonneau; the second idea demands that one's neighbors be discouraged, but in the absence of a large family, the really right solution to the whole problem is to own an automobile with a body that is not inviting. Of course, one could attach an old-fashioned body to the car and shame the neighbors out of riding in it. This is a severe remedy and is almost as hard upon the owner as it would be upon the neighbors.

The best solution after all lies in the unconsummated future. When the roadster type of body came into vogue, autoists hailed it with delight. They said to themselves, "This is the right answer. The rumble seat is not sufficiently inviting and autoing will be a pleasurable undertaking." These autoists counted without considering their neighbors. The self-invited guest is not rebuffed by the prospect of sitting in the "monkey seat" at the rear. Most owners of cars have the impression that he would rather sit on the radiator than be debarred of the ride in someone else's car. Unfortunately, the average autoist has friends whom he would like to entertain, but he finally reaches a state of mind which prevents him from inviting his real friends to partake of his hospitality if it is in the form of holding down a monkey seat in the vicinity of the rear axle of a short wheelbase automobile. The rumble-seated body, therefore, fell short of the whole requirement by many yards.

Referring specifically to the large number of autoists who really cannot afford to run a big touring car day after day, when as a matter of fact they only need a runabout type of body, it remains to give them a convertible runabout body, if the same can be so designed that it will permit of inviting a friend along without feeling that the guest will be reduced to the status of a servant through force of the seat he is compelled to occupy in the car. To satisfy this exacting situation, it will tax the ingenuity of the best type of body designer, with the possible chance that the problem cannot be solved at all.

By way of a suggestion, a design is here presented that offers possibilities. Fig. 1 shows the body as it would appear on a Hudson car with a wheelbase of 100 inches, and all the other earmarks of comfortable touring. The general appearance of the body is in full accord with the latest ideas along torpedo lines with a fore-door and an overhanging cowl from the dash back for the protection of the occupants of the seat. The idea involved in drawing the body to fit some particular make of car is in order to show how it will appear in practice, but it will be understood that the body may be fitted to any automobile provided the dimensions are made to accord with the characteristics of the car.

Fig. 2 is a side elevation of the body showing the accommodation seat thrown back ready for the occupant. The seat proper, marked A, is formed out of the back of the main seat, and the lazy back for the accommodation seat marked C is formed by upholstering the underside of the trap door of the torpedo stern. The dotted lines show how the back of the seat proper swings back to form the accommodation seat and how the top trap door is swung up to form the lazy back of the accommodation seat. Fig. 3 is a plan of the body showing a main seat that is 36 inches across at the front edge, and which flares outward toward the back. The accommodation seat, which is 15 inches deep and 14 inches wide, is shown open, leaving a space 11 x 14 inches for the lower extremities of the occupants of the accommodation seat. Under all ordinary conditions, the accommodation seat is folded up, that is to say, the back of the seat proper is latched in its normal position, and the trap door of the torpedo stern is closed. The general appearance of the car, when the accommodation seat is folded up, is that of a smart torpedo-stern type of runabout fitted with fore-doors.

Allen-Kingston leading Simplex in the hour race

Brighton Beach Fizzle

ADVERTISED LABOR DAY SPEED CARNIVAL MADE A POOR SHOWING; EVENTS UNDER FIVE MILES IN VIOLATION OF RULE 78 OF THE CONTEST BOARD

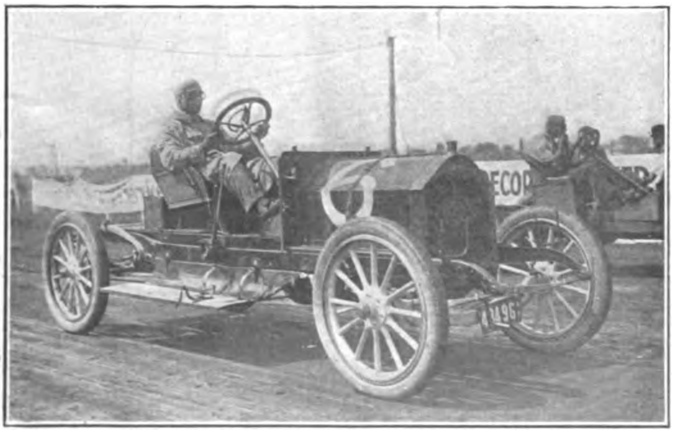
PROBABLY 6000 persons paid $2.00 a head to sit in the grand stand and witness the Labor Day performance, which was advertised by the promoters as a speed carnival, the assumption being that Brighton Beach would be the scene of some of the greatest events that were ever heralded to take place at that Motordrome. It was a two-day affair, opening on Saturday at 2 P. M., skipping Sunday and reconvening on Labor Day at 11 A. M. The weather situation was distinctly bad on Saturday, rather indicating that Old Boreas had a hunch that the racing was not to be up to much—Boreas was right.

The first race was between the S. P. O. cars at five miles. The next was a ten-mile dash from the scratch, after which the first of the hour races was put on. In this race the Knox, while distinctly in the lead, had the misfortune to damage a valve at the thirty-ninth mile, which left the Simplex to win by itself. The splendid performance of the Knox up to the time of the accident proved to be one of the bright spots in an otherwise dull situation. By actual count just thirteen automobiles participated in the races. It was unfortunate that the big Benz was raced under unofficial conditions; it will be remembered that rule 78 of the Contest Board demands the use of automatic electric or mechanical timing equipment in all races under five miles. This equipment was not provided as after events proved.

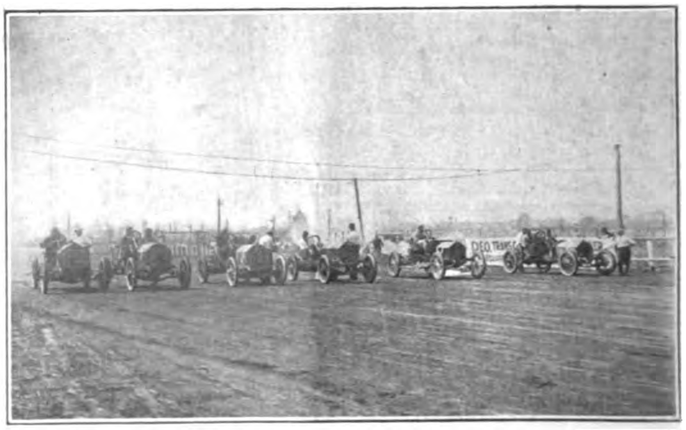
The patrons, expecting to witness some good racing, were not much impressed by 13 cars and a battery of motorcycles—some of them, no doubt, had visions of the promises made on the billboards and in some newspapers. The summary of the event, which was really a Monday affair on account of bad weather on Saturday, is as follows:

SUMMARY OF THE EVENTS AT BRIGHTON BEACH

No.	Car	Driver		Time	Position
Event 1—Five miles; 300 cubic inches and under. Class E.					
17	S. P. O.	M. P. Batts		5:16 2-5	1
23	S. P. O.	Jean Juhasz			2
Event 2—Mile time trials.			**First trial**	**Second**	**Third**
2	Simplex	Robertson	53 3-5	52 2-5	
3	Darracq	Kerscher	53 2-5	52 4-5	
4	Simplex	Beardsley	1:00		
6	Black Crow	Otto F. Rost	1:15 2-5		
10	Isotta	Ray Howard	1:10	59 3-5	
19	Benz	Oldfield	50 2-5	50 4-5	49 4-5
Event 3—Ten miles for 600 cubic inches and under. Class E.					
2	Simplex	Robertson		10:12 1-5	1
5	Fiat	Kerscher			2
Event 4—One hour race.					
2	Simplex	Robertson		55 7-8 miles	1
5	Fiat	Kerscher		51 miles	2
10	Isotta	Howard		48 miles	3
4	Simplex	Beardsley		44 miles	4
6	Black Crow	Rost		44 miles	5
1	Knox	Oldfield		39 miles	6
7	Allen Kingston	Ormsby		25 miles	7
Event 5—Ten miles. Under 300 cubic inches. Class E.					
8	Mercer	E. H. Sherwood		10:46 4-5	1
17	S. P. O.	M. P. Batts			2
Event 6—Ten miles. Under 600 cubic inches. Class E.					
2	Simplex	Robertson		10:08 1-5	2
Event 7—One hour race.					
2	Simplex	Robertson		55 miles	1
7	Allen Kingston	Ormsby		48 miles	2
8	Mercer	Sherwood		35 miles	3
10	Isotta	Howard		No finish	



Black Crow driven by Rost, fifth in the hour race



Start of the hour race, won by Simplex, No. 2

Engineering Section

DEVOTED TO THE DISCUSSION OF ENGINEERING PHASES OF AUTOMOBILING, INCLUDING DESIGNING AND CONSTRUCTION FEATURES OF PRODUCTS, AND INFORMATION TO AUTOISTS

A PLACE FOR EVERYTHING AND EVERYTHING IN ITS PLACE—TAKEN AT THE MAXWELL SPARE PARTS BUILDING

REPAIRS have to be made sooner or later, no matter how good an automobile may be, and the pertinent question is, How much will the necessary parts cost and how long will it take to procure them from the maker of the particular car? If the parts are not carried in stock the time that will elapse between ordering and receiving will include the interval of making, after the manufacturer makes up his mind to stop regular work long enough to put a man on one small job. In this way it is more than likely that the cost of the repair parts will be very high to the maker, and if he fails to charge all the cost to the owner of the automobile he will suffer a pecuniary loss.

That any customer would be so lacking in acumen as to patronize a maker of automobiles who is losing money, is not believed. Lack of stability of an enterprise is a sure sign that the purchase price of the product is not the measure of the whole cost to the purchaser. The manufacture, under such conditions, is likely to be slighted. Repair parts, if they can be had at all, will be charged for according to the need for money of the maker; worth, that is to say intrinsic value, will have little or nothing to do with the transaction.

Legitimate prey, if the man who wants a repair part is to be regarded as such, is still entitled to a chance. What chance will he have from a maker who fails to include in his "wise" provision any means for taking care of his customers?

Among the makers of automobiles, taking the better class, it is the custom to run a repair department and to have a separate storeroom for spare parts. In this way if an order comes in for a repair part it is handled by "part number," and it is stored in a bin under that number, or according to a system that allows of promptly locating the part wanted so that it can be expressed to the customer the very day it is ordered.

If an automobile is worth anything to the user, it is a loss, in a pecuniary sense, to have the automobile placed out of commission during the time that it is undergoing repair. If that time is shortened by having the parts in stock at the plant of the maker, in this is a source of profit to the user of the car.

From the quality point of view it is not too much to venture that a car that is protected by repair parts in stock, awaiting instructions to ship, is considerably better than a car that is not backed up by a stock of spare parts, even if the builder of the latter does say that it never gets out of order and will never have to be repaired.

There is a superstition among many users of automobiles that it is cheaper to go to a machine shop and have parts made to order than it is to go to the maker of the car and purchase spare parts. It is even claimed that parts made to order are better than those regularly made—they ought to be, they cost so much more; but are they better?

It looks like a simple matter to whittle out a crankshaft from a billet of steel; surely a machinist will be able to do the work within a few hours; this is the reasoning. When the owner of a car undertakes to put this fine reasoning into force he licenses a repair shop to run up a bill that will be anything from $100 to $300, nor can he be sure that the crankshaft will be good for the purpose after it is made.

It is no different with a connecting rod, cylinder, piston, or even a bolt. The experience of a concern that is doing things daily in a large way is surely to be compared favorably with the experience of a man who has to undertake the work for the first time. Willingness to do a job at some one else's cost is not experience. Quality is not the companion of mere desire; experience is what counts.

The critic who from his pedestal on high says that a design or a part is not as good as it ought to be may be quite honest; the question is, who is his authority, or what is his ground for expressing his criticism? If a critic states that a part is not well made, and he offers to make a better one, it only remains to allow him to build a whole new automobile; what is the sense in placing so good a piece of work in so poor a frame? Why spoil the splendid job that he promises by using it under such disadvantages?

In the meantime it is not too much to say that it is a nice feeling to have, that comes with the assurance that spare parts can be obtained readily, and that the cost, even though it may seem a little high, is a known quantity and within the limit set by the importance of the undertaking as represented by the value of the service that the car will render when it is in good working order.

First Aid to the Injured

HUGO ERICHSEN, M.D., TELLS THE AUTOIST HOW TO TAKE CARE OF WOUNDS, FRACTURES, DISLOCATIONS, ETC., UNTIL THE DOCTOR ARRIVES

IT seems strange, when you come to think of it, that people carry an elaborate kit of tools, as a precaution against accidents to their machines, but usually make no provision whatsoever against mishaps to themselves. And yet timely aid is of the greatest importance in many such emergencies and even death may occasionally only be averted by a prompt stoppage of hemorrhage.

In considering automobile accidents there are practically only four forms of injuries with which we are here concerned, namely, bruises. wounds, fractures and dislocations.

For the proper treatment of these conditions, it is not necessary to carry an extensive outfit of medicaments and appliances, and the automobile medicine case may therefore be quite compact and take up but little space. I would suggest some mild antiseptic and disinfectant in a powdered form, such as formidine; a powerful hemostatic, such as adrenalin, the active principle of suprarenal glands; a small jar of moist sterilized gauze, some adhesive plaster, and a small collection of bandages of various sizes. To these it might also be advisable to add some remedy that will quiet pain, but this should only be administered when the suffering of the patient is almost unbearable.

Whisky is useful when collapse is threatened and the patient evidently requires stimulation, that is to say when the face is very pale and the extremities are cold. But the indiscriminate use of whisky, which is so common in all forms of accidents, cannot be too strongly condemned.

Contusions or bruises are often met with as a result of minor automobile accidents and are sometimes complicated by a hemorrhage under the skin. In the way of medication nothing can be done under such circumstances except to stop pain if it is excruciating. But the patient should be placed in a comfortable position until a physician arrives. At the same time all tight-fitting garments must be loosened, so that the circulation and respiration will not be interfered with. If the injured one looks pale or has fainted, it is also advisable to place him in such a position that his head will be lower than his heels. If the contusion is not of much consequence, the application of some analgesic ointment or balm, which is now purchasable in the convenient form of tubes, will afford the sufferer considerable relief.

Wounds are of more importance than contusions because they may involve a severance of one of the large arteries of the body and thus give rise to hemorrhage endangering life. If the wound is of small extent, the bleeding may be stopped effectively by the application of adrenalin or by exerting direct pressure upon it. In case one of the main arteries has been cut, however, which is apparent when the blood spurts from the wound, it is necessary to exert pressure at some point along the course of the artery between the site of the injury and the heart. This is best effected by what is called a tourniquet, a contrivance that can be easily improvised. If the wound is located just above the elbow, for instance, a handkerchief is tied around the upper third of the arm and a small block of wood, cork or smooth stone inserted between it and the skin directly over the artery, which can be readily detected by its pulsation. An iron rod or wooden stick is then introduced between the skin and the handkerchief, opposite to the block or stone and turned until the arm is constricted and the bleeding stops.

FIRST AID TO THE INJURED

Fig. 1—Emergency bandage; injured hand bandaged by means of handkerchief and placed in sling. Fig. 2—Shows application of improvised tourniquet. Fig. 3—Shows how parasols and umbrellas may be used for splints in case of fracture; held in place by three large handkerchiefs

Small wounds should be carefully cleansed by means of pure water and, after being dried with a clean cloth, dusted over with formidine or some other antiseptic powder. Everything that is brought into contact with them should be as clean as possible. They may then be covered with a layer of moist sterilized gauze and bandaged, remaining in this condition until the patient can receive proper medical attention. In the case of clean cuts, it may be advisable to bring the edges of the wound together with strips of adhesive plaster, which may be allowed to remain in place until the healing process is complete. Every particle of foreign matter must be removed, however, before a wound is treated in this manner, for if it is not, it will give trouble later on by causing inflammation and suppuration.

In transporting a wounded person to some locality in which he can receive medical aid, he should be disturbed as little as possible and carefully protected against the sun, the dust of the road and the attacks of insects.

Sometimes it is impracticable to expose the site of a hemorrhage by partially undressing the patient, in which case no time should be lost in ripping the clothing and getting down to the site of the trouble without delay. In many such instances prompt action is required in order to prevent a fatal issue, since a person may bleed to death in a very short time, if one of the largest arteries is severed.

A layman can distinguish between a fracture and a dislocation of a bone by the excessive motility of the injured part in the one case and its immovability in the other. Sometimes the altered shape of the limb will reveal the nature of the injury, but in other instances it may be necessary to remove the shoes and garments. In such cases no attempt should be made to pull them off. Instead they should be cut away by means of some sharp instrument, such as a knife or shears.

When a limb is dislocated or sprained, but little can be done except to keep it as quiet as possible until it can be restored to its normal condition or subjected to proper treatment by a physician.

In a case of fracture, however, much may be done to render the patient's condition more bearable by means of improvised splints, that keep the injured extremity at rest and prevent the broken ends of the bone from rubbing against each other. Canes, parasols or umbrellas, if they are at hand, may be used for this purpose. In the open field, away from any habitation, even the branches of trees may have to be resorted to.

Letters

DISCUSSING MATTERS OF INTEREST TO USERS OF AUTOMOBILES; RELATING EXPERIENCES OF SOME; RAISING QUESTIONS OF GENERAL VALUE; AFFORDING OPPORTUNITY TO THOSE WHO WISH TO CONTRIBUTE

What Is the Best Automobile for This Case?

Editor THE AUTOMOBILE:

[2,352]—If I am not taking too much of your valuable time I would like very much to have a little advice in regard to what kind of an automobile to buy and would thank you very much for an answer. I am hardly able to own one, but have the fever, and others around here are indulging in cars so that I want one, too. I live in the country and our roads are fair. Part of the roads are piked. A few are hilly and sandy. There are so many kinds of automobiles to be had around $1,000 to $1,200 that it is difficult to make up one's mind as to the one to select. Then, there are secondhand cars advertised that are said to be made over so that they are as good as new; what about them?

Custar, Ohio. U. E. L.

The editor of THE AUTOMOBILE begs the question, but the following may be of some relevance:

Wilkins—"Do you have trouble with that 'used' car that you purchased a while back?"

Bilkins—"Couldn't have more if it was a widow with eight children and I married it."

Permanent Magnets Are Not Hardened All Over

Editor THE AUTOMOBILE:

[2,353]—Please tell me if permanent magnets are hardened all over?

N. H. G.

Pottstown, Penn.

No. See Fig. 4; the parts that are hardened are indicated by lines; the hardening is confined to a portion near the ends of the magnets.

Electric Lighting Is Now Regular Equipment

Editor THE AUTOMOBILE:

[2,354]—I am about to purchase an automobile and would like to have you advise me as to the expediency of adapting electric lighting on the same, also, would you retain the acetylene system as an auxiliary to the electric system if the same is adapted?

PETER N. COMBS.

Altoona, Penn.

It would be a good idea to retain the acetylene system, and by following the plan as shown in Figs. 1 and 2, it will be possible to do so. As the illustration depicts, the electrical fixtures are applied to the acetylene lamps by means of lamp attachments that permit of using the electric lights with the lamp standing up in front of the burner, but if it becomes necessary to use acetylene, the lamps are folded down as in Fig. 2.

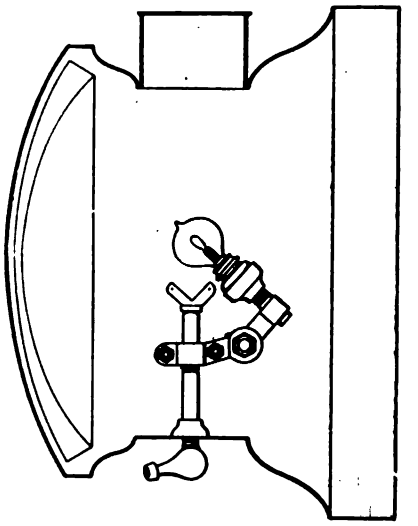


Fig. 1—Acetylene lamp with an electric lighting attachment; showing the same in position

Bevel Gear Steering Gears Are Not Irreversible

Editor THE AUTOMOBILE:

[2,355]—I have been told that bevel gear steering gears are irreversible; is this true? Please illustrate one and state why it is irreversible, if it is.

ADAM B. CONVERSE.

Erie, Penn.

No. The illustration Fig. 5, is of just such a gear, it being made of a 14-tooth pinion meshing with a 56-tooth gear; the ratio is therefore as 1 is to 4. Since the teeth are such that the gear will rotate with the same ease in either direction under a given amount of pressure, then there is nothing irreversible from this cause, and since the ratio is as 1 is to 4, it remains to be seen that it takes 4 times as much pressure for the pinion to drive the gear as it does for the gear to rotate the pinion; but there is nothing irreversible about a 4 to 1 ratio.

Would Like to Know Just How Wiring Is Insulated

Editor THE AUTOMOBILE:

[2,356]—Please illustrate the way that wire is wound on the kick-coil of an ignition system; this system, as I understand it, has but one winding of fine wire. What size of wire would you use?

ED. F. CALIGAN.

Racine, Wis.

The coil is shown in section in Fig. 3. The size of the wire may be No. 40 B. & S. gauge. It should be what is known as double-cotton covered magnet wire. The core should first be insulated by several wraps of oil-paper. Over the paper the wire is wound. In order to get 1-2 pound of wire on, it will be necessary to wind closely. The ends should have insulating washers; they can be made of red fiber or other suitable material.

Is Camphor Good for Cleaning Cylinders?

Editor THE AUTOMOBILE:

[2,357]—I have been informed that the addition of camphor to lubricating oil will lessen the accumulation of carbon in cylinders of gasoline engines.

As a subscriber to your paper, will you kindly inform me if this is correct and if the use of same would in any way harm the engine?

W. S. N.

New York City.

The Editor of THE AUTOMOBILE is not favorable to the plan; if some autoist can relate experience space will be given.

It is not necessary to confine discussion to camphor; other substances have relating properties.

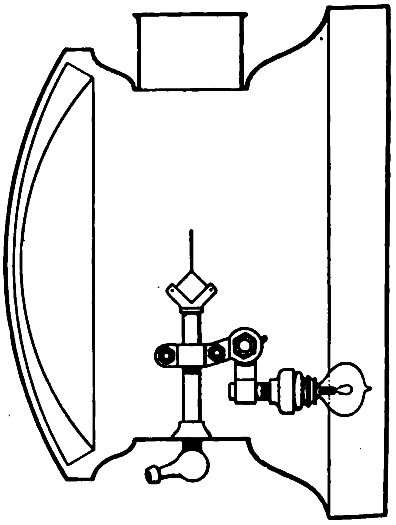

Fig. 2—Acetylene lamp fitted with an electric lighting attachment with the same thrown back out of the way

Just Why Is It Necessary to Change Gears?

Editor The Automobile:

[2,358]—As a new subscriber and also the new owner of an automobile I come to you with what may seem to you to be a simple case, but the fact remains that I am in trouble and what is equally to the point I do not understand just why I should be. Since my motor will go fast or slow accordingly as I manipulate the spark and throttle levers, why is it that I have to slide the gears, and why, too, do they make such a thundering clatter every time that I do undertake to slide them? Other autoists seem to get on very well; it is but rarely that some of them cause such a noise. Also, will the clatter that is made when I slide the gears do any damage?

New Owner.

Newark, N. J.

The clatter that you cause, according to your own version of the performance, is due to the fact that you are not deft enough to so slide the gears that they will engage. Instead of engaging they rub against each other, and, considering the impact of the mass at the speed that they travel, it is to be expected that the ends of the teeth will be all battered up before long. Just how long it will take you to ruin the transmission depends upon the quality of the material of which the gears are made and the length of time that you take in learning how to manipulate the sliding-gear lever.

Just why it is necessary to employ a system of change gears in conjunction with an internal combustion motor would be a simple story to relate to one understanding graphics. By the use of graphics it is possible to plot two curves, one of which would portray the power of the motor at its several speeds, and the other would indicate the power demanded to run the automobile at its several speeds. At all events it will be easy to understand that the power available from the motor at any speed at which it is being run must be equal to the power required to run the automobile at the speed that it is geared to run, or the motor will stall; that is to say, it will shut down.

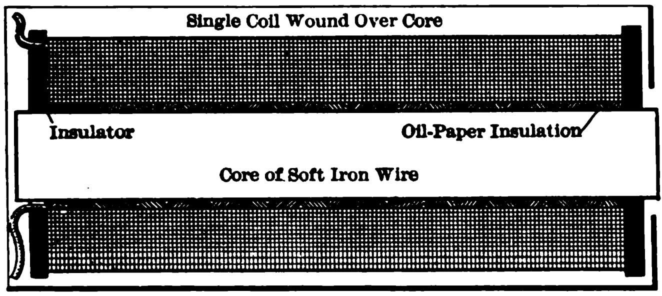

Fig. 3—Section of a kick-coil as used in starting a motor, showing how the windings are insulated

The power that may be delivered from a motor is not the same at all of its speeds; in fine, the power increases with the speed. Unfortunately the power does not increase in direct proportion to speed, and after the speed is increased beyond a certain point, the power ceases to increase, but a point in the speed range is finally reached where there is an actual falling off.

Referring now to the power demanded to run the automobile, it is simple to understand that the faster the car is required to go, the more power it will take. But if the roads are soft more power will be required than when they are hard, and if the roads are hilly the power demanded going up hill will be more than when the car is traveling upon a level hard road, and the least power will be taken when the car is going down grade; if the grade is sufficient, that is to say, if the hill is steep enough, and the car is going down, the power may be cut off; it might even be necessary to apply the brakes.

Having thus recited the well-understood general conditions under which a motor is required to deliver its power, it remains to point out that the reason why the change gears are used is because the power needed to propel the car on a level hard road at high speed is not as much as that which is demanded to drive the car up hill, and when the hill is reached, in order to be able to go up, the motor is permitted to run fast, but by sliding into a lower gear, the car is geared to go up the hill slower. The result is that the power required to go up the hill is kept within the ability of the motor. Likewise, as the road condition demands, the gear ratio is adjusted to harmonize the relation of the motor to the demand; the variable being the speed of the car, as it must be, for the reason that it is not possible to either alter the road or make the motor deliver more power than it is capable of delivering.

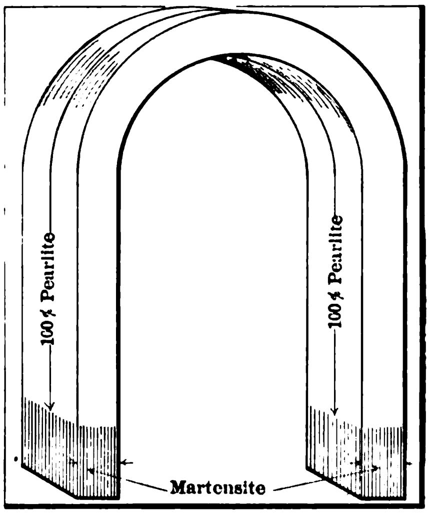

Fig. 4—Illustrating the hardened part of permanent magnets as used in magnetos

Referring to the question of sliding the gears with a view to eliminating the noise complained of, the points to be observed are as follows:

(A) Remember that the mating gears must be going at a common speed when they engage if noise is to be avoided.

(B) No two automobiles seem to act alike, and it is necessary for the driver to ascertain just how each car performs on the road and work accordingly.

(C) When the mating gears are rotating at substantially the same speed, deftly shift the gears. Deftness is half the battle. It is not an occasion on which languor will be enjoyed.

(D) How is the manipulator to know when the mating gears are rotating at a common speed? It is too bad that some rule can not be given for this.

(E) In dropping from a high to a low speed it is usually the case that a slight pause is all that is necessary before shifting.

(F) In changing from a low to a high speed the plan is to go up gradually. Accelerating the car is the process. If low gear is in, slide to second, then to third, and if there is a fourth, then go into it. Be deliberate—there is no occasion to act panicky.

(G) If, in attempting to slide the gears, it is found that they "refuse," back out, wait a second, then try again; don't linger.

(H) If the system is "selective," it is always possible to find some one of the selec-

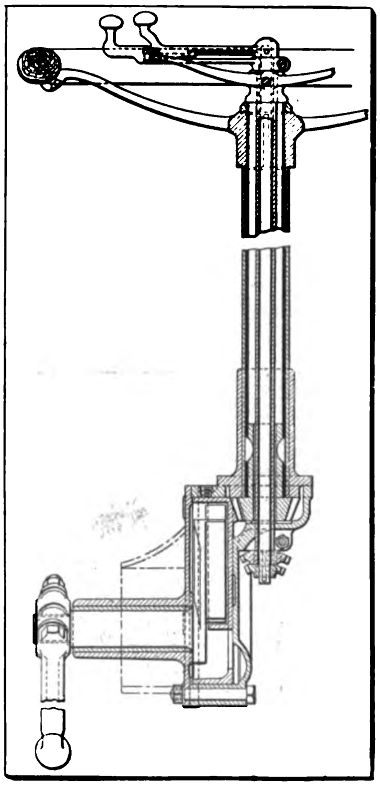

Fig. 5—Section of a steering gear showing the relations of a bevel gear and pinion for this service

tions that will work without clattering. Try to judge of the speed that the car is making; having decided as to this point, try to match up.

(I) It is also feasible to alter the speed of the motor so that the sliding can be accomplished without clashing; some designs of automobiles really indicate that changing the speed of the motor a little is a necessity.

(J) Bravery is worth more than any other one quality; timidity is the bane of the autoist; deliberate long enough to make sure of the ground, then go ahead—go at it like a whirlwind.

Wants to Know What Sizes of Wire to Use

Editor The Automobile:

[2,359]—I would like to make a single coil to use on my motor and having a high-tension distributer it is my purpose to build a coil that will be better than I would be likely to be able to purchase at any price that I can afford to pay. I have plenty of time at my disposal and understand electrical work sufficiently to make it possible for me to properly insulate the windings. I am somewhat at a loss to determine just what would be good sizes of wire to use and how much of each size, referring, of course, to the primary and secondary windings.

Amateur.

Philadelphia, Pa.

The first thing to take notice of is the space available for the windings. If this matter is so disposed of that choice may be taken, it is more than likely that the primary coil should be composed of 1-2 pound of No. 18 B. & S. gauge double-cotton covered magnet wire, and the secondary winding should be composed of 1-2 pound of No. 36 double-cotton covered magnet wire. Silk covering is better. If space permits use more than 1-2 pound of wire in each instance.

Motor Heats Up—Radiator Remains Stone Cold

Editor The Automobile:

[2,360]—I have a 2-cylinder, opposed, water-cooled motor, and while it has served me well for two years, it now shows signs of wear and I would like to have you tell me why the motor heats up and the radiator remains stone cold.

P. H. F.

Salt Lake City.

Since the radiator is placed to wipe the heat out of the water and the heat is put into the same at the cylinders of the motor, does it not stand to reason that, if the radiator remains cold, the water is not being circulated? What is it that is utilized to circulate the water in your case? Is there a water pump? If so, does it not stand to reason that it is shirking its plain duty? Have the pump repaired.

Mont Ventoux Hill Climb

BROUGHT THE LONG-STROKE SINGLE-CYLINDER MOTOR PERFORMANCE INTO BOLD RELIEF; ACCIDENT TO GASTE'S SIX-CYLINDER ROSSEL

AVIGNON, FRANCE, Aug. 29—An average of 37.6 miles an hour with a standing start up a winding hill measuring 13 1-2 miles, beginning with a grade of 6 per cent., increasing to 9, 10 and finally 13 per cent., can be considered satisfactory going even for a big racing car, but when the performance is accomplished by a little one-lunger of slightly less than 4 inches bore it is nothing less than astounding.

Nine years ago when the attempt was first made to capture the wild Mont Ventoux hill the mere ability to reach the top was considered remarkable. Automobiles have progressed some since 1902, as is proved by the fact that Boillot with his one-lunger Lion-Peugeot this year beat all comers by racing to the top in 21 minutes 30 2-5 seconds, getting very near the record established a year ago by a 155-millimeter, four-cylinder Brasier racing car.

The test is the high-water mark of hill-climbing, for starting at an altitude of 970 feet, the course rises in 13 1-2 miles to 6,216 feet, the grades being 2 1-2 miles at 6 per cent., 6 miles at 9 per cent., 4 miles at 10 per cent., and the remaining portion beginning at 10 and ending at 13 per cent.

This year's climb was marked by an accident which put Gaste's six-cylinder Rossel out of business almost at the commencement and made the victory easy for Boillot's Lion-Peugeot. While taking a sharp turn at nearly 60 miles an hour the Rossel skidded and went over into the ditch, with a broken arm for the driver.

The Lion-Peugeot which then took first place is the familiar single-cylinder racer of 3 9-10 by 10 inches bore and stroke, holding all world's records for its class. The motor was designed by Boudreau & Vernet, of Paris, and is remarkable, in addition to its long stroke, by the use of three intake and three exhaust valves.

In the same section second best time was made by the Spanish car Hispano-Suiza, having a four-cylinder motor of 2 1-2 by 7 4-5 inches bore and stroke. Piloted by Chassaigne, it was clocked in 22 minutes 31 2-5 seconds. Third place went to Giuppone on a

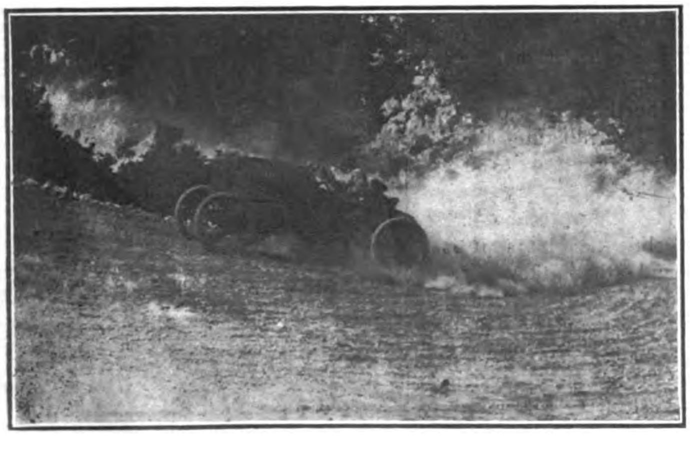

Fig. 1—Lion-Peugeot single-cylinder motor making sharp turn at 60 miles per hour or better

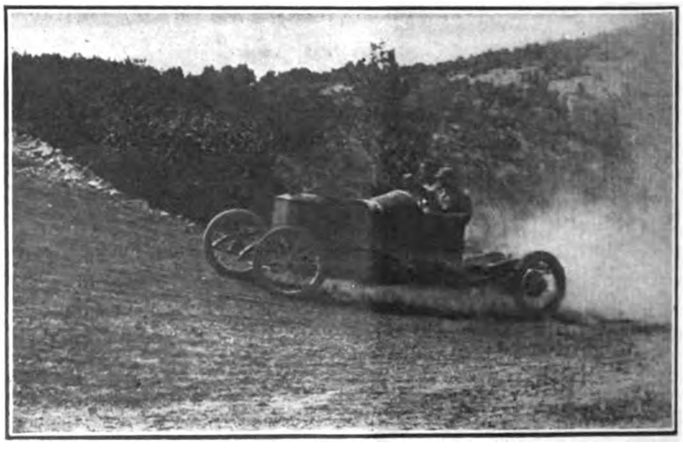

Fig. 2—One of the Hispano-Suiza cars on the turn just behind the Lion-Peugeot

Fig. 3—Hispano-Suiza going like mad around the curve, trying to take first place—actually crossed the tape second

one-lunger Lion-Peugeot identical with the winner, and fourth position to a Hispano-Suiza similar to the one which took second place. Ignoring all class distinctions, however, second best time was made by Zuccarelli's Hispano-Suiza of 3-3-10 bore by 6 1-2 inches bore. It was clocked in 21 minutes 56 1-5 seconds, or 25 3-5 seconds behind the winner. The following is the summarize result, which should be scanned with more than a little interest by the autoist recognizes the potential force of the argument in favor of fuel economy. It will be understood that the long-stroke single-cylinder motor was here in competition with even six-cylinder motors, which are not famous for fuel economy, and, while the larger motors probably delivered more power, the fact remains that they did not cover the whole distance finishing so quickly.

Some Ultra-Refinements

DISCUSSION OF CARBURETER DESIGNING; HOW THE CRANKCASE MAY BE RENDERED IMMUNE FROM GRADE TROUBLE, ETC. BY PINGREE GROVE

SCANT attention is given to refinement in point of mechanical details, especially in accessory construction, and if the automobile, as a machine, is to ultimately stand on the same stable platform as the locomotive and other older machines, some of the engineers engaged in the work will have to take the time to point out the frailties and indicate the way to final success. It will be something of a task, to be sure, and the chances are that no one man will be able to do very much about it.

At all events, the sooner the work is started the better, and the less of it there will remain for other hands to do. It was only a few issues ago when it was stated, on page 275 of THE AUTOMOBILE, that "some rubber mixtures used in tires wear ten times as long as others." This was found to be so, according to the statement of P. Breuil, by tests that were actually made at the Conservatory for Arts and Sciences. Rubber was very aptly described as an organic material which has strayed into mechanics. It may be too much to state that rubber is not the only organic material that has strayed into mechanics, especially the mechanics of the automobile.

It is probably true that the tire problem is being wrestled with every day in the year, and, knowing its many complexities, it may be that it will be necessary to trust to the makers of tires to reduce a difference of ten to one down to a point where the sound of it will be somewhat less alarming.

Synthetic discussion, especially as it relates to the rubber problem, usually ends in words, but many of the remaining problems of the automobile are so well in hand that this character of discussion is not necessary. Take the carbureter problem for illustration. Why should there be so much talk on the side of undemonstrated theory? Its many angles are quite generally appreciated, and yet it is handled as a subject just as if it were a monoplane or some other really new contrivance.

Just to show that the carbureter problem will sustain discussion without departing from known quantities, let us take up the matter of the accumulation of water and the result of its presence in gasoline. Surely none will deny that gasoline is hungry for water; every dabbler in the chemistry of hydrocarbons will testify to the fact that pentane (chymogene) will coax water through a glass bottle with a ground-in stopper placed to prevent the water from passing through anything but the walls of the bottle. The hunger of hydrocarbons for water increases as the volatility of the product, and in proportion as it is anhydrous.

Automobile gasoline holds very little pentane or other hydrocarbon distillates lighter than hexane, but it is a gatherer of water to a greater or less extent in any event, and for good results in practice, the design of the equipment must be such as to enable the operator to eliminate the water. The design, on the other hand, should be such that it will not take the better part of an hour to find out what is the matter when a drop of water plugs up the orifice of the nozzle as shown in Fig. 2, which is a characteristic type of construction with an enlargement below the throat of the orifice. The globule of water is wedged in, having floated up in the stream, and it being too large to pass through the constricted passageway, and too tough to be torn asunder, lodges there and serves as a corking medium that will effectually stall the motor every time it happens.

What is the remedy for trouble such as this? Let us say it is best pictured when the water globule is not permitted to enter the carbureter. How is this to be done? Some say all the gasoline used should be poured through a chamois skin. If the skin first dampened by water it will not then let the gasoline through, but water will be free to pass. On the other hand, if the chamois skin is first soaked in gasoline, then it will refuse to pass water. But in these phenomena will be found the ground for suspecting that water is not likely to be kept out of the fuel system merely because the chamois skin is used to filter the gasoline. It is only a question of days when a more or less water-wet chamois skin will be used, and then the water, which is nearly always present in gasoline, will get by.

The best protection against water lies in a plan which controls the flow of the same and a means for separating it out of the gasoline before it reaches the constricted throat of the nozzle.

How is this to be done? Certainly not by assuming that all water is to be kept out of the carbureter. Even if it is possible by eternal vigilance to put nothing but unwatered gasoline into the tank, the first time the automobile is washed a little water will probably be forced into the carbureter by way of the float-bowl vent hole. But even if this is not likely to happen, the vent hole is there and the gasoline, being thirsty for water, will drink in some of its aquatic companion through the same vent hole.

If the gasoline is fed by gravitational force there will be still another vent hole somewhere in the system, through which water will creep. If the vent holes are not provided the gasoline will not flow, hence the remedy does not lie in the direction of sealing up the system.

In the further discussion of the problem Fig. 1 will be referred to for the purpose of elucidation. The gasoline enters at the top of the float bowl, and in this example an ante-chamber is provided. The orifice for the needle valve instead of being flush with the floor of the ante-chamber extends up to the roof. As the gasoline enters, then instead of passing down into the bowl below, assuming that the needle is off of the seat, it settles in the ante-chamber with the heavier portions laying on the floor, and the more volatile (lighter) portions will migrate toward the upper level.

The orifice leading to the seat of the needle valve instead of being quite open is constricted at the throat, and the wall is thinned down to a knife edge around the extremity. If water rises due to agitation it cannot enter the throat of the extremity of the passageway because the opening is too small, nor can the water lodge on the rim of the crater, due to the knife edge, which affords no lodging place. The result is that the globules of water, like marbles, will roll off of the rim when the carbureter is vibrated, and they being heavy will fall to the bottom of the ante-chamber. An outlet is provided near the bottom of the chamber, through which the water accumulations may be drained at intervals.

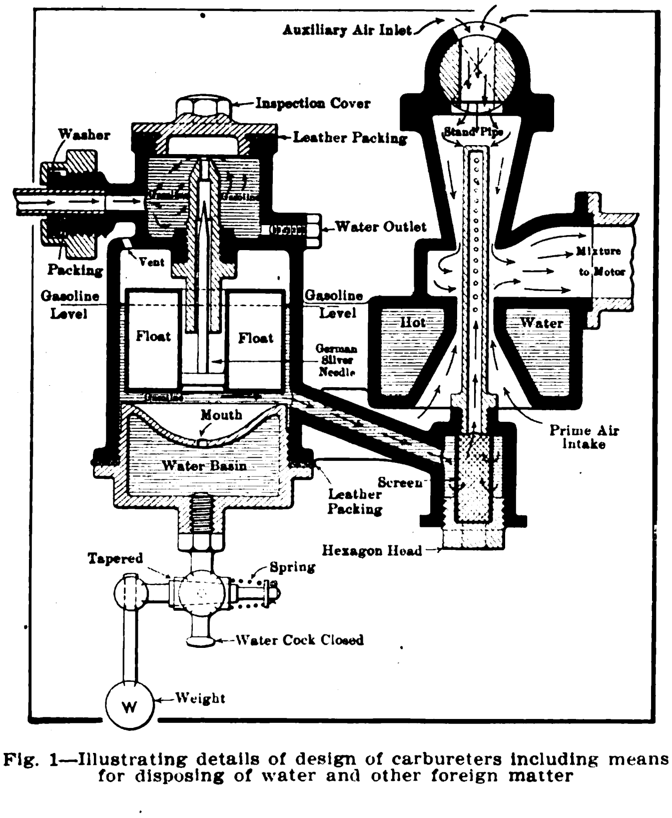

Fig. 1—Illustrating details of design of carbureters including means for disposing of water and other foreign matter

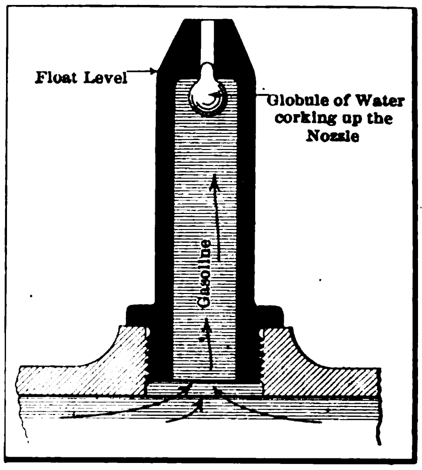

Fig. 2—Depicting the way by which a globule of water serves as a cork, preventing the gasoline from flowing out of the nozzle

But this precaution is of small avail in view of the presence of a vent hole for the float bowl. True, all the water that can find its way into the float bowl must be squirted in by the "washer" or be coaxed in by the anhydrous gasoline. To guard against water from these causes the bottom of the float bowl is provided with a water well formed out of the bottom cover by means of a core. This well is provided with a large mouth and at the low point a hole is drilled large enough to permit the globules of water to pass down into the well.

It must be remembered that if water will stop up the throat of a nozzle as shown in Fig. 2 it will stop up any other small hole so that care must be taken to have the hole leading to the well large enough to prevent the passage of water.

A cock is screwed into a threaded hole in the boss, formed in the bottom wall of the well. This cock is for the purpose of draining the water out of the well at rather frequent intervals; on this account the cock shown is so designed that it will work easy, but the handle is weighted and hangs down when the cock is closed. In addition to this the valve of the cock is tapered and a spring is placed on the reduced end in such a way as to put tension in the direction of forcing the tapered valve up against the tapered seat. A little lubricating oil, if placed on the seat, will hide in the pores of the metal and the valve will work easy at all times although it will be perfectly tight. The weighted handle will keep it from opening.

The rim around the mouth of the well will catch all the water and lead it down to the opening at the bottom so that only gasoline will flow from the float bowl to the filter at the bottom casting for the standpipe. The screen below the standpipe is there to pick up all the scum that may reside in the gasoline, it being in the form of water and other impurities. About once a week it will be found necessary to unscrew the screen and clean it off. It will choke up the passageway if this operation is neglected.

The screwed-in cover at the top is placed there to permit of opening up the ante-chamber and cleaning the same out from time to time. A leather packing-ring is used to make a tight joint when the cover is screwed in; the same kind of a joint is used to make a tight seam for the well, which also forms the bottom of the float bowl.

The waterjacket is limited to the walls that enclose the rich mixture; it is a well-appreciated fact that the liquid in the float bowl should be maintained at a constant temperature in order that the viscosity will be the same at all times. If the temperature of the liquid is not constant, then the amount of the same that will flow through the nozzle orifice will change.

In order to supply enough heat to vaporize the liquid gasoline the hot water is placed in the position of greatest advantage, *i. e.*, in a jacket concentric with the primary air intake and in juxtaposition to the primary nozzle.

The auxiliary air is not allowed to contact with the jacket walls; the cooler it is the better, provided the gasoline is vaporized before it is mingled in the stream of auxiliary air. As

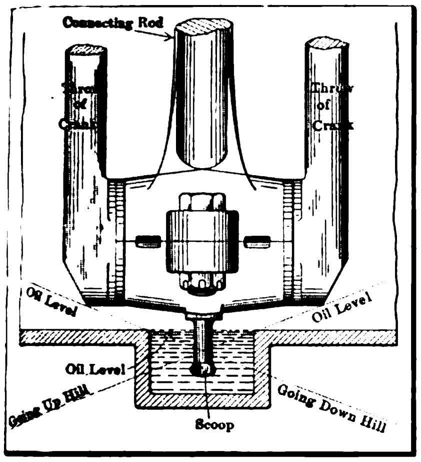

Fig. 3—Section of a crankcase showing how the scoop on the cap of the connecting-rod can be compelled to dip in the lubricating oil on a steep grade

for the remaining details of design, they are unimportant from the point of view of this discussion, and in the regular course all the ideas as here enumerated can be utilized without adapting the form of carbureter as here shown.

When a car is going up grade, or even when it is descending, the lubricating oil, instead of lying level on the bottom of the pan, surges to one end—the low point. What is the result? The crankpin bearings are starved. If the hill is a long one the bearings may run dry and the result will be that the "brasses" will be melted out, or, at least, the argument based on profuse lubrication will be without a leg to stand upon.

It is quite possible to so fashion the bottom half of the crankcase that this trouble will be aborted and Fig. 3 shows how the design may be carried out. In this illustration, which is a section through the bottom half of the case, the scoop on the boss of the cap is made long enough to dip into a trough, and the trough is so designed that the depth of oil is sufficient to prevent the end of the scoop from being uncovered when the car is going up or down hill and the oil runs to the low level. By means of broken lines the action is clearly indicated so that further discussion is uncalled for.

Strangle Well Located in the Intake Manifold

When a motor is running at high speed for a time, the flow of gasoline becomes substantially a stream out of the nozzle of the carbureter and if this flow is suddently arrested as it will be if the motor is suddenly slowed down or brought to rest, some of the gasoline, due to inertia, will remain in the intake in liquid form and it will remain there long enough to strangle the motor the very next time an attempt is made to use the same. Even under running conditions it is possible for the liquid to pile up and when it does the performance of the motor will be irregular, if, indeed, it is not so bad as to demand drastic attention before much headway can be made. As a suggestion of a way to keep out of this character of trouble reference may be had to Fig. 4, which is a cross-section of the manifold at a point just above the carbureter joint. The extended portion is the strangle well; it is formed by a core during the casting process and the depression just in front of the baffle flange is for the purpose of allowing the liquid gasoline to roll down through the hole into the well below. When the liquid goes into the well it remains there until it is vaporized, when it comes up through the same hole as gas and is swept on to the motor. In this way the action is automatic, and the only time that it becomes necessary to unscrew the cap screw at the bottom of the well is when water accumulates; this should not happen under ordinary conditions of operation.

Motor Serves as a Good Brake on a Grade

It does not take a motorist very long to discover that it is at the price of brake linings that he uses these necessary devices on long down-hill runs at frequent intervals. Many autoists have contracted the habit of allowing the motor to serve in the capacity of a kinetic brake, and how well it will work in this capacity depends upon the design and the manner of its installation.

When a planetary gear is a part of the equipment, by throwing the same into low gear it is possible to go down almost the steepest hill without using the brakes; it is not bad practice to do so and if the hill is a little too steep all that is necessary is to put a little pressure on the brakes to aid the low gear and the descent will be made in comfort and safety.

When a sliding gear system is used instead of a planetary gear, it is just possible that the drag will be below the demand if the hill is steep, and in such cases it is possible that the plan as shown in Fig. 5 will ultimately prevail. This illustration is of a valve, the same to be placed in the intake at a point between the carbureter and the cylinders of the motor.

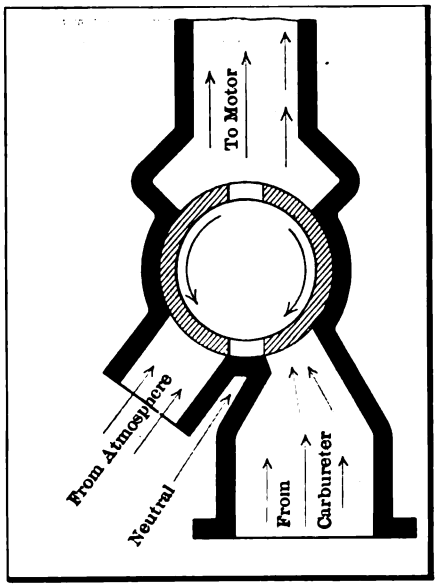

Fig. 5—Valve in the manifold just above the carbureter, placed there to permit of using the motor to slide down hill without using the brakes on the car

When the motor is running in the ordinary way the valve is turned so that the gates admit the mixture to the motor, but when it is desired to go down an ordinary hill the valve is turned so that the gate shuts off the mixture from the carbureter and admits fresh air only. If the hill is very steep the valve is turned to neutral, in which position the valve shuts off communication; the result is that the motor will pull a vacuum and quite an increase in the "drag" will result; in this way the car may be gradually maneuvered down a mountain side with scarcely a chance of having to call upon the brakes.

The fresh air swept into the combustion chambers of the cylinders will help to free the surfaces of any carbon residuum that may be lurking there, and the motor will land at the bottom of the hill clean and cool, ready for a long spurt and a quota of exacting work. A car that is fitted with good brakes and some means that will permit of sliding down hills on a kinetic basis is likely to be more safe to ride in, which is a point in the right direction, and the depreciation, as it is induced by brake-work, will sink to a low level. Even without any special provision, however, the motor may be used to advantage in retarding the motion of a car on a down grade, and the plan is recommended as being superior to the excessive use of the brakes.

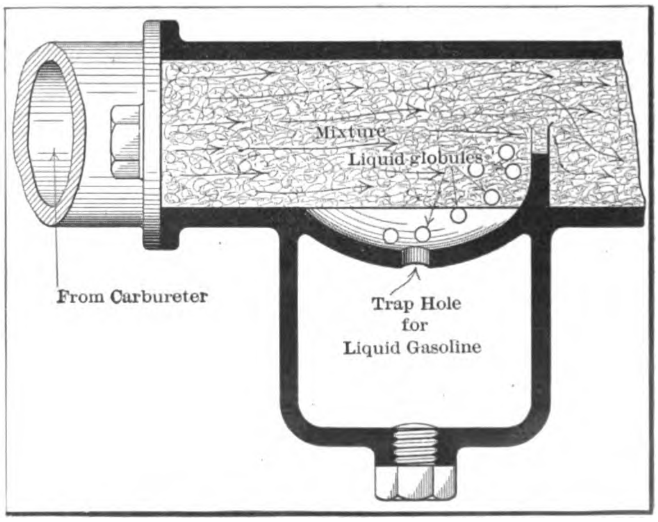

Fig. 4—Trap in the manifold, designed to catch the liquid gasoline and hold it there until it vaporizes, when it will be released

Don't

MORE SHORT-METER ADVICE TO THE TYRO—AND THE EXPERT—THE FOLLOWING OF WHICH MAY SAVE THE MOTORIST HEAPS OF TROUBLE, PERHAPS SOME MONEY, AND PROBABLY A LAWSUIT OR TWO

Don't imagine that color is so fast that it will not fade out if the automobile is stored in a dark room. To preserve the nice appearance of a car it is necessary to store it in a room that is well lighted.

Don't suppose that the varnish will not crack when it gets old; everything does, even the complexion.

Don't suppose that old age is at the bottom of all the cracking that is to be observed; some cars are so abused that the varnish is not all that cracks..

Don't wound a sensitive nature by coarse treatment; highly finished surfaces of bodies are most sensitive; like human characters of the sensitive class, they are easily wounded.

Don't allow soap and dirt to accumulate over the surfaces of bodies unless it is desired to change them to a mottled appearance.

Don't preach fresh air for human beings to the exclusion of the fresh air that will preserve the general good appearance of automobiles; it may appear funny, but while paint and varnish are devoid of the same character of lungs that supports man, they seem to breathe and are poisoned by impure air.

Don't fail to keep coal gas, carbonic acid and sewer products out of the garage; the varnish will mottle up on such feed.

Don't throw away your common sense when you take up with the automobile; there is occasional room to apply it.

Don't fail to add a little horse sense if the supply of the other kind runs out.

Don't imagine that all the "bronco busters" are dead; the way some automobiles are managed would suggest that the supply is inexhaustible.

Don't take two drinks on the ground that your system needs the stimulant, and then spill all your private affairs into the willing ear of the chauffeur—he may leak.

Don't believe all you hear about homes being mortgaged to buy automobiles; the fable tellers of that vintage are crying "sour grapes."

Don't tolerate short measure; you are entitled to every gallon of gasoline that you have to pay for; show the rascal up.

Don't let the repairman put a boy on a man's job; he may do more damage than he is worth; it would be better to pension him off and have done with it.

Don't purchase 10 cents' worth of supplies from a road-side repair shop and then tip the man a quarter; it makes it bad for people who know better than to breed such vermin.

Don't have your tools so handily placed that the light-fingered gentry that infest road houses will be able to relieve you of them.

Inexpensive Portable Garage

DESCRIPTION OF A FIRE-PROOF GARAGE, BASED UPON ACTUAL EXPERIENCE IN AN EFFORT TO SOLVE THE PROBLEM OF STORING A CAR

WITH the great majority of motor car owners, both present and prospective, the garage problem is one of much importance.

To house a car in a public garage involves a very considerable monthly expense; the care taken of the machine is not always satisfactory; and unless the garage is close at hand this arrangement usually presents some little inconvenience, and especially to those owners who operate their machines themselves. Moreover there are large and increasing numbers of autoists to whom the upkeep of their cars is a pleasant diversion, which together with the economies resulting from caring for their machines themselves, are denied when the machines are housed in the ordinary public garage.

On the other hand, to expend several hundred dollars in erecting a private garage even on one's own property is frequently objectionable and the average man hesitates still longer to make such an investment on rented ground which he may not desire to occupy permanently.

To meet this situation and provide an inexpensive private garage which can be moved readily if desired and which will be fireproof so as to meet even the most rigid building and insurance regulations, recourse may be had to corrugated iron or sheet iron in other forms, with results which will be entirely satisfactory.

Under a proper design, using standard stock materials, a substantial and attractive building sufficiently large to house one car and leave ample shop and work room, and which will accommodate a visiting car on occasions, can be secured for as little as $35.00, excluding labor, and if the owner does not care to himself do the work of erection, which is very simple, the whole finished garage, including labor, need not involve an investment of more than $50.00.

The floor plan of such a garage, in which is indicated the space occupied by a touring car of average length and the remaining shop and workroom space, is shown in Fig. 1, while in Fig. 2 the position of such a car and a roadster in addition is outlined. In this particular garage sheet iron, formed to represent rock-faced stone, was used for the sides, with regular corrugated iron for the roof. With drab paint on the sides and red paint on the roof it is difficult at a short distance to distinguish this building from one built of stone, with a red tile roof, and the whole appearance is very pleasing.

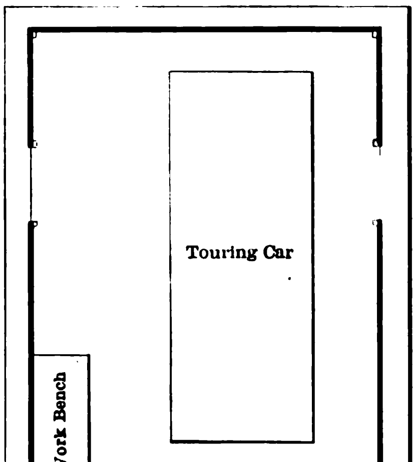

Fig. 1—Plan of the little garage showing the space utilized for the touring car and the working space around it

Fig. 3 shows front and side elevation—in addition to the plan. The more common V-roof would be somewhat simpler to frame and cover than the type shown which is selected because of its being more attractive in appearance. The right door is hung one foot from the corner, while two feet are left on the opposite side, where space is provided for the work bench.

The 9 feet of doorway provide ample clearance for the entrance of the machine, which is substantially 6 ft. wide over the running boards. One window on either side, located about two-thirds back, furnishes ample light and ventilation. The doors should each be 4 ft. 6 in. x 8 ft. high. The size of the windows should be made to suit the size of material used for the sides of the building.

The framing of the structure, which is made entirely of 2 x 4s in standard lengths, will be the same, irrespective of the material selected for the sides and roof. The following pieces of 2 x 4s will be required for the frame: For the uprights eight pieces 8 ft. long; for the horizontal members, four pieces 16 ft. long and four pieces 12 ft. long; for the roof, four pieces 12 ft. long. There will also be required for the stiffening of the roof frame eight pieces of 1 x 3-in. material, 8 ft. long. For the doors, 1 x 3 material will be required as follows: Four pieces 8 ft. long; four pieces 4 ft. 6 in. long; two pieces 12 ft. long.

To erect the frame of the building form a 12 x 16-ft. rectangle on the ground with two pieces 2 x 4s, 16 ft. long and two pieces 12 ft. long. Nail the corners securely with wire nails about 5 inches long, placing the four sills on edge. Then nail 8-ft. uprights inside each corner and nail to their tops a rectangle of two 16 ft. long and two 12 ft. long pieces similar to that formed by the sills. Two additional uprights are then to be placed on the sides, midway from the front to the rear, all as shown in Fig. 4. Two additional uprights are to be used for the hanging of the doors as shown in light lines.

The simplest siding is made of standard corrugated iron, in 8-ft. lengths, with 2 1-2-inch corrugations. If this material in 24 gauge galvanized costing about $4.40 per square (100 square feet) is used two pieces of 1 x 3-in. boards 16 ft. long and two pieces 12 ft. long will be required in the framing of the sides. These pieces are to be nailed to the sides of the 2 x 4 frame half way up or 4 ft. from the ground. The total cost of the corrugated iron for the sides will be about $20.00. For about 10 per cent. more sheet iron, stamped to represent rock-faced stone, can be secured. The strips of the latter run horizontally, however, instead of vertically and with them three nailing strips 1 x 3 in. will be required on each side, calling for six pieces 16 ft. long and six pieces 12 ft. long.

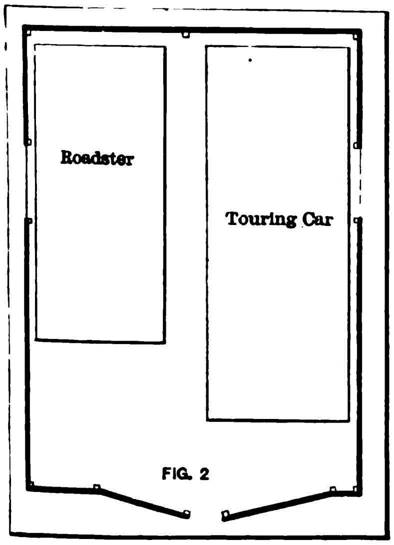

FIG. 2

Fig. 2—Floor plan showing a roadster, and a touring car on the floor, and the room that is left.

With either character of siding the doors can be framed and covered conveniently, but with the rock-faced stone sheeting, which comes in lengths of 5 feet, it is simpler to make each door an even 5 ft. wide instead of 4 ft. 6 in. and this extra width of the doors will be found to be an advantage rather than a disadvantage in the use of the garage. Both kinds of siding are fastened to the frame with special wire nails and washers which are procurable with the sheet metal at a few cents a pound. About one pound of nails will be required for each 200 square feet of siding.

As respects the roof frame, if simplicity and ease of construction outweigh attractiveness the roof shown in Fig. 3 can be modified to a simple V roof for the framing of which six pieces of 2 x 4, 8 ft. long and one piece 18 ft. long will be required, together with two pieces of 1 x 3-in. material, 18 ft. long. The six pieces 8 ft. long run from the peak, which should be elevated 3 ft. to give good drainage to the eaves and provide for an overhang of the roof of about 8 inches, after the fitting at the peak is done. The 16 ft. 2 x 4 is the ridge or peak member and the 1 x 3 are nailing strips to be placed midway between the eaves and ridge.

Galvanized corrugated iron is the best material for the roof, no matter what siding material is selected. It is to be bought in 8-ft. lengths also and nailed on directly to the roof frame. To make the ridge water-tight, a piece of ridge cap 18 ft. long will be required. This is standard material which can be secured with the other iron.

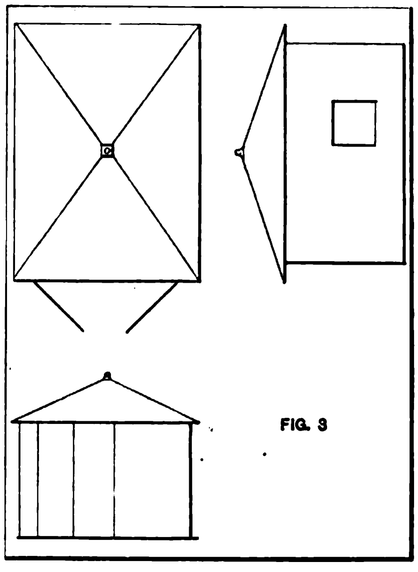

FIG. 3

Fig. 3—Elevation, in two planes, also looking down upon the roof of the little garage

If such a roof as is shown in Fig. 3 is selected, four pieces of 2 x 4, 12 ft. long to run from the central peak, which is 3 ft. above the eaves at the center of the building, to the corners and to project 8 inches for the roof overhang will be required; and for nailing strips two pieces of 1 x 3, 8 ft. long and two pieces of the same material 6 ft. long will be necessary, these to be nailed to the main 2 x 4 frame midway between the peak and eaves. At the peak the 2 x 4s are to be sawed at an angle so as to make a ridge butt joint and opposite members are to be securely fastened together by nailing short 1 x 3 pieces on either side as shown by Fig. 6. The first two members can best be sawed and nailed together at the proper angle on the ground. This pair will then be placed in position and nailed at the corners of the building, when the remaining two members can be fitted and fastened in place.

With this character of roof some cutting of the iron, the 8-ft. lengths of which run from the peak down on each of the four sides, will be necessary, but the roof is designed to be symmetrical, and with reasonable care in cutting the 8-ft. lengths it will be found that only one cutting of each piece will be necessary and that each part will exactly fit at its proper place, so that there will be no waste of material and no extra fitting. This type of roof requires four pieces of ridge cap, 12 ft. long, also a peak ornament which is standard material, to make it water-tight and to give the roof a finished appearance.

In providing windows glazed sash about 24 x 30, as may best suit the width of the siding used, may be found in most lumber yards at from 50 to 75 cents each and may be easily arranged to run in simple slots nailed to the strips.

To provide a smooth and satisfactory floor a cheap concrete made of one part cement, four parts sand and six parts gravel or crushed rock or even cinders, may be employed, this floor costing about 5 cents per square foot; or a light board floor can be laid for a total

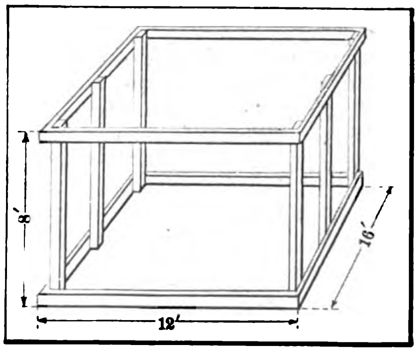

Fig. 4—A skeleton of the building, showing how the framing is joined

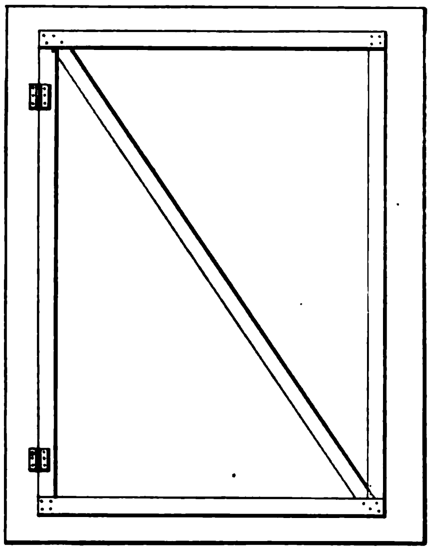

Fig. 5—Big door of the little garage, presenting the plan of the framing, showing the diagonal bracing to prevent the door from sagging

cost of about $10.00. For anything, except indefinite permanent use a couple of loads of cinders, costing about 50 cents delivered, will answer all requirements, providing the cinders are tamped firmly into the ground. This latter character of floor will be reasonably smooth and will absorb oil, water and other moisture, without disturbing the smoothness and without making any mud.

The doors are to be framed to the width selected about as shown in Fig. 5, which provides ample braces to keep the doors from sagging or getting out of shape.

With either construction of the sides or roof mentioned the work will be found to be simple and the results satisfactory. The problem of construction is well within the mechanical scope of any person having the slightest aptitude of mechanical plans and work and the finished appearance, in any case, will be pleasing, especially if the building is painted after completion as suggested.

If portability is desired it will be found entirely possible to dismantle the building at a future date and re-assemble it on another location, without any difficulty and without any loss of material except possibly a few nails, representing an outlay of a few cents.

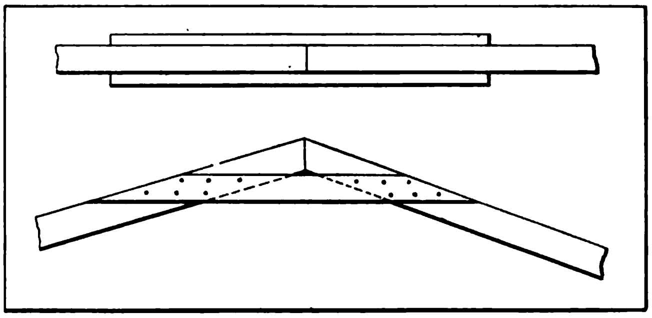

Fig. 6—Roof framing; a simple plan; as strong as it is easy to make

In putting up a building of this character it is well to remember that there are ordinances and insurance regulations that will have to be complied with. In some localities it is necessary to allow a certain distance between the residence and the garage.

Good Service from Dry Cells

JAMES S. MADISON SHOWS HOW A SATISFACTORY IGNITION SYSTEM MAY BE PROVIDED WITHOUT A MAGNETO

THIS article is intended for the autoist whose car is not equipped with a magneto or storage battery. All of the better class of cars are at present provided with magnetos, which give, without question, the most certain and satisfactory system of ignition; but there are many cars that depend upon dry cells as their principal or auxiliary source of electric current. Others are equipped with storage batteries; this is especially desirable in the case of cars provided with a coil that consumes an extravagant quantity of current. In view of the amount of time required to recharge a storage battery, the attention necessary, the inconvenience involved, and the very satisfactory service that may be obtained, by proper management, from dry cells, there does not seem to be any real reason why an automobile of the gasoline type should be equipped with a storage battery unless its coil is so wasteful as to render dry cells impracticable and its owner is willing to go to the expense of purchasing two storage batteries, so that one may be recharged while the other is in use. Of course, it would be simpler and wiser and not much more expensive to put in a new coil and magneto, or, what would be less expensive, a new coil and dry cells. The only way to determine accurately whether a coil is consuming too much current is to test it or have it tested with an accurate ammeter, the scale of which is divided into tenths—the small, low-priced pocket instruments will not do.

The test is made as follows: The wire, connecting the coil and battery, is disconnected from the battery, and the free terminal attached to the binding post of the ammeter; another wire is then connected to the free pole of the battery and the other binding post of the ammeter. The engine is then started and run at low speed. The reading of the ammeter will show the current consumption of the coil at that particular speed. Should the pointer of the ammeter move backward, interchange the two wires connected with the binding posts.

In no case should a coil consume more than 0.5 ampere under the above conditions; it should in most cases use not more than 0.2 or 0.3 ampere to insure economical service.

The writer recently tested the coils—one vibrating, the other non-vibrating—on two cars of different make (two-cylinder cars). In each case the coil consumption was the same, 0.2 ampere. With four and six-cylinder engines the consumption would be greater.

Assuming that the coil shows only a moderate consumption and that the owner is using dry cells without getting a satisfactory mileage, the fault undoubtedly lies in the method of installing the cells, and of taking care of them—a fault that may be easily corrected with gratifying results. While it is true that an occasional coil is defective, the vast majority of them are entirely reliable and free from faulty features. The vibrating coil is often condemned as consuming excessive current, when all that it needs is a simple adjustment of the vibrators.

In order to get the best results from a battery of dry cells, by cutting the cost of ignition per mile to the lowest possible figure, it is only necessary to observe certain simple precautions in buying and setting up the dry cells. But with the best coil on the market and the best battery, satisfactory results cannot be obtained if there are any poor connections. One single, unsuspected poor connection may cut down the battery efficiency 50 per cent.

More than half the battery troubles encountered by users of dry cells is due to ignorance or unwillingness to take a little trouble. If any one is skeptical on this point let him take a look into the battery boxes of a half a dozen automobiles.

There are a number of different kinds of dry cells on the market. Like other articles of commerce, some are good and some are not. For the protection of the consumer there should be stamped in clear letters, on the bottom of each cell, the date it was manufactured. This is of great assistance to the buyer, as it enables him at once to tell the age of the cell. Without the stamp it is impossible even to guess how long the cells may have been standing around on the shelves or in some more objectionable place, unless the accumulation of dust and dirt on the outside should be an indication. One should, of course, test every cell purchased, whether it is dated or not, with an ammeter. Each cell of the usual size should show from 20 to 30 amperes; those reading above or below these figures should be avoided. If the car is equipped with a battery box by the manufacturer it will probably be of the right dimensions to accommodate the proper number of cells; if not it will be advisable to buy a metal box or have a wooden one made. For eight cells of the usual size, 2 1-2 by 6 inches, the dimensions of a wooden box are as follows: Inside measurements—length, 10 1-2 inches; width 6 inches; height 6 inches. It should be made of 1-2- or 7-16-inch boards, preferably of soft wood. There should be a partition 5 inches wide running lengthwise through the center to form two divisions, each of which will hold conveniently four cells. In addition there should be a strip of wood 11 1-2 inches long by 1 3-4 or 2 inches wide to go across the top lengthwise, provided with a screw at each end, for the purpose of holding the cells securely after they are in place. The bottom of the box is lined with one thickness of rubber matting or two thicknesses of Canton flannel or other soft thick material, in order to protect the bottom of the cells from the constant jolting. The cells should be prepared as follows: All the binding screws should be removed and the flat contact surface of each one brightened by rubbing it vigorously across a piece of fine sandpaper or emery cloth. The hexagonal nut on the carbon terminals of some old cells, which may be had for the asking at any dealer's, in case there are none at hand, should be removed and brightened on both sides in the same way, for use on the new cells. It sometimes happens that the terminals of unused cells are partially covered with pitch, or verdigris. This should be removed carefully and thoroughly. Emery cloth cut in strips about 1-4 inch wide, or, what is more convenient, "dental cloth finishing strips" (which are strips of linen covered with sand, that may be obtained from any dentists' supply house), should be used for cleaning and brightening these terminals. After the zinc poles (the small brass projection soldered to the rim of the zinc cylinder of the cell) of all the cells have been cleaned, screw on one of the hexagonal nuts. This is to provide a larger and more effective contact surface. This is an important detail and should not be neglected. The manufacturer provides a sufficiently large contact surface at the carbon pole, but only about one-half as much at the zinc pole. The nut should be screwed on firmly but quietly in order not to loosen the terminal. When all the cells have been treated in this way they are placed in the battery box. To prevent them rubbing against each other or the box, the interstices between the cells is filled by packing in firmly clean, dry, cotton waste or something similar. Small portions should be put in at a time and then packed down with a small rod or screw-driver. If this is done carefully, there will be left no space for any cell to move in—the box, cells and waste will form a solid, firm, compact mass in which there will be no motion of any of the individual parts.

The top strip of wood should then be placed in position, and the screws at each end started but not driven home. For connecting the cells together, the ordinary form of battery connections may be used. One of the most popular forms is slipped on the battery cell poles by a little pressure; it will remain in position indefinitely. This and other quickly adjustable varieties are satisfactory so far as putting them on is concerned, but the objection to most of them is that the contact surface is too small. The kind shown in Fig. 1 is very good. They may be purchased for 25c. per dozen and possess the very decided advantage of having copper terminals with large surface. The ordinary objection urged against them is that they are troublesome to put on and keep in place. This is only a valid objection if one is careless. They can be put on so securely, without any special effort, that they will not loosen during the life of the cell.

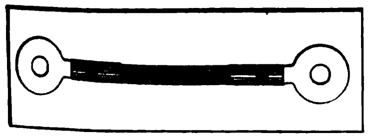

Fig. 1—Ordinary form of battery connection

Whatever form of connections is used, each terminal should be cleaned and brightened with emery or sandpaper. The cells should then be connected together in series or in series multiple, as one may prefer. No matter which method is used, the connections should be attached as follows: One end is placed against the hexagonal nut on the screw forming the carbon terminal, the round nut is screwed on with the fingers and then tightened firmly and carefully with a pair of pliers; the other end of the connection is attached to the zinc terminal of the adjoining cell in the same way, but greater care must be used to secure it, in order not to loosen the soldered joint between the brass screw and zinc cylinder. If the cells are to be connected in series, this operation is repeated until all are connected except the carbon and zinc poles of the last two cells. The carbon pole is then connected with the switch, and the zinc pole with the coil. Experiments have clearly demonstrated that while the connection in series is the most widely used, it is the most expensive and therefore unsatisfactory method of connecting dry cells. The series multiple connection is superior in every way, giving greater mileage at a lower cost.

The following table from "Operation of Motor Cars and Motor Boats," National Carbon Co., shows the comparative results of engine tests with multiple batteries:

Arrangement of Cells	Hours Service	Estimated Miles Service	Estimated Cost per 100 Miles
1 Set of 4 in Series	20	400	$0.25
2 Sets of 4 in Series-Multiple	70	1400	.15
3 Sets of 4 in Series-Multiple	120	2400	.11
4 Sets of 4 in Series-Multiple	170	3400	.08

These figures were obtained by practical tests in actual service with a four-cylinder, four-cycle automobile engine. In each case the battery was required to run day and night continuously until the engine began missing. This continuous service is the severest kind, because the batteries do not have a chance to rest. By using the same equipment and the same size batteries in service having periods of rest, the above figures will be greatly increased and the cost per 100 miles proportionately decreased. There is one other point; the joints should be electrically good; it is rarely that this is true; good joints will always be assured if they are soldered. The average man seems to think that a mechanically tight fastening of the wires to the terminals is all that the situation demands. The electrical resistance of one poor joint is far greater than the electrical resistance of perhaps a mile of wire. The energy, under such conditions, is dissipated at the joints, and the work that the battery will then do is very meager indeed. The time required to properly clean all the terminals and put a drop of solder on them, using a heated soldering iron for the purpose, is but slight. There are fluxes that come in paste form that will help out materially. The real secret of success lies in having the joints quite clean—emery-cloth is a good abrasive—bathe the parts in gasoline to remove every trace of grease. They go ahead.

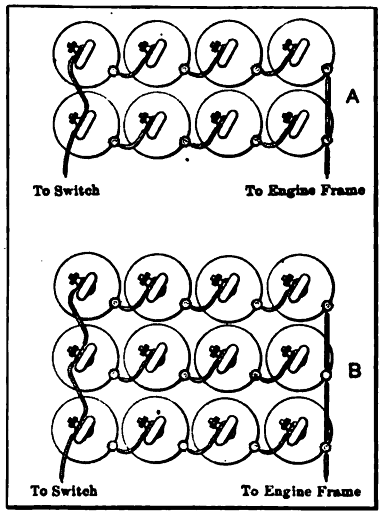

Fig. 2—Method of arranging dry cells when four are used in series; (A) Two sets in series-multiple; (B) Three sets in series-multiple

Repainting the Old Car

M. C. HILLICK TELLS THE AMATEUR HOW TO GO ABOUT THE TASK OF RENOVATING THE BATTERED BODY AND CHASSIS

SHORN of its surface beauty, with bruises and fractures sufficiently deep and numerous to make the work of bringing the car up to a finish a task of no mean importance, the first work consists in cleaning all parts of grease, dirt and miscellaneous accumulations. Then sandpaper the surface of the body with No. 1-2 paper, fetching it in this way smooth and sleek, with all fractures and defects cleaned out. In case of the metal body, scrape over all abrasions, dents and other disfigurements, and sandpaper the surface in the same manner as the wood surface is treated.

Beat up some tub or oil ground white lead in turpentine, adding a suitable coloring pigment, and adjusting it finally to carry, say, one part raw linseed oil to six parts turpentine. Apply this to the wood surface with a bristle brush and slick it up nicely to insure uniform and sure drying. For the metal body, first coat, use, for the most part, a negative pigment so far as its action on metal is concerned.

Make it to carry a strong percentage of raw linseed oil and apply to the surface sparingly but with a uniform film of pigment. Let this first coat of surfacer dry thoroughly, after which, this process completed, go over the surface carefully, and with a hard drying putty, fill up all cavities, and other defects. Any exceptionally rough places should be draw puttied, or putty glazed, as the work is variously designated.

The main thing in puttying, or in putty glazing, is to round up, fill up, and make the defects as little as possible, or, best of all, eliminate them altogether.

After 24 hours prepare and apply to the surface a coat of surfacer, or, as it is known to the trade, rough stuff. This can be shop-made or bought ready mixed, requiring, for immediate use, letting down with turpentine to a proper brushing consistency. This consistency, however, is a good bit heavier, or should be, than ordinary coats of paint. If made in the shop take equal parts, by weight, of any good American filler in dry form and white keg lead, working them up to a stiff paste in equal parts of couch japan and rubbing varnish, then thinning with turpentine to the desired consistency. On the whole, however, it is practically as cheap per gallon to buy the rough stuff prepared ready to use, and in this way you save the cost of mixing.

Apply four coats of the rough stuff in as many days, laying the first coat off lengthwise of the panels, second coat crosswise, so alternating in laying off, thus securing a more dense and compact body of pigment. Next take some of the rough stuff and add to it either enough yellow ochre or Indian red to give the pigment either a shade of yellow or red, and, thinning with turpentine, apply over the rough stuff. This serves as a guide coat to enable the painter, when rubbing the surface down with water and artificial pumice stone, or rubbing brick, to judge more quickly and accurately concerning the condition of the surface—when it has been rubbed enough, quality of rubbing, etc.

The day following this application of "stain" or "guide," rub the surface down to a smooth and level condition, free from all blemishes, with the artificial rubbing stone or brick, and water, using this latter medium plentifully. Rub with straight out and return strokes of the arm, holding the stone firmly upon the surface, and keeping enough water on the surface to prevent the stone from gumming up and scratching the work.

Circular motions of the stone during the rubbing process endanger the quality of the surface. After completing the rubbing process wash with clean water and stand the surface aside overnight for the elimination of moisture.

Next sandpaper the surface very lightly with No. 00 sandpaper, dust off and apply the desired color coat. With one coat of color and a coat of varnish-color, or with two straight coats of color, two coats of rubbing varnish, and a coat of finishing varnish the body surface should be sleek and trim and quite brilliant enough to give a good account of itself in any company.

Meanwhile, the chassis will require attention. After cleaning up thoroughly go over the parts carefully, and all fractured, and shattered, or lightly bruised places, touch up with a pigment composed of, say, three parts white keg lead and one part coloring pigment of any preferred shade, beating the mass up in turpentine containing raw linseed oil in the proportion of one part oil to four parts turpentine. After three days sandpaper the surface of the chassis throughout, and apply with a camel's hair brush a coat of either white lead and some other pigment, or other surfacer, whipped out to a smooth working consistency in turpentine, fortifying the mass with raw linseed oil in the proportion of one part oil to seven parts turpentine. Brush the pigment out clear and fine, and after forty-eight hours putty all surface defects of whatsoever nature with the hard drying putty previously described. Should any coarse patches of surface exist, thin some of the hard putty down with turpentine and glaze all such parts. Let the putty dry for a couple of days and then sandpaper, avoiding, meantime, cutting through the first coat of surfacer. Upon working the putty down to a perfect level with the general surface, clean and dust off carefully and apply a final coat of surfacer composed of white lead and some desired coloring pigment whipped out thin in turpentine, with a bit of raw linseed oil added, say, one part oil to ten parts turpentine, using a camel's hair brush to lay on the surfacer.

Lightly sandpaper this coat in due time and apply color, then varnish-color or glaze, stripe, and over a coat of clear rubbing varnish, finish.

The Badly Shattered and Worn Job

This is the sort of work which the painter dislikes, it being difficult, as a rule, to get a price sufficient to adequately compensate him for services rendered. The old paint is found scaling and flaking off and the surface shows numerous gouges and fractures. The first step consists of burning the old shaky, flaky finish entirely off, using a burning torch or lamp. These lamps use gasoline, and in case their employment renders insurance policies invalid, procure a small rubber tube of the required length, and equipped with the proper devices, one end with small burning point and the other with attachment for gas fixture, affix to the nearest gas fixture, and with this medium—nowise equal in power to gasoline, to be sure—proceed to burn the old, crispy garment of pigment from the surface. In doing this work heat the paint until it becomes soft, and then with a broad-blade, half-elastic scraping knife, held at an angle of about 45 degrees, push the point under the soft paint and lift the pigment from the surface, doing the work as cleanly as possible. After burning the old paint away, sandpaper thoroughly until a clean, solid wood foundation is secured. Then prime with either raw linseed oil and some pigment medium, or with some one of the numerous excellent patent primers. We thus have the badly battered and shattered surface fairly and rightly started toward a new and sound finish. It only remains to carry it through with the several processes provided for such work, which includes rough stuff, color, rubbing varnish, and so on.

It is rarely that the chassis has to be burned off. Simply cut all the running parts down hard and clean with coarse sandpaper, scraping the shattered places down with a steel scraper until a sound, healthy surface condition is reached, after which, upon sandpapering, apply a coat of primer as advised for the body. Bring to a finish upon the order of procedure already detailed.

To Paint Without Burning Off.

With a steel scraper dig away all the scaly and shelly pigment, working down to the solid foundation. Dig out, and clean out the old cavities, after which prime with some reliable material, working the medium into all the holes and fractures. Next apply some second coat material made up of white lead, raw linseed oil, turpentine, and a coloring pigment. Let this coat dry firmly and then apply the following: Dry white lead, three parts; best bolted whiting, one part. Beat to a consistency which lets the pigment work freely from the point of the putty knife in equal parts of brown coach japan and rubbing varnish, letting the mass out a bit with a sprinkle of turpentine. Take a broad knife and plaster the putty over the surface solidly, drawing it out smooth and to a uniform depth under the edge of the knife. Obliterate and face up all inequalities. Permit the putty to harden up several days—four, at least—and then with a rubbing brick or stone dipped in raw linseed oil proceed to rub down the mass, working it out gradually to a smooth, level surface.

Glaze with this same putty and face up all the rough parts of the chassis and in due time bring the proper surface with sandpaper.

Let the body surface, after rubbing, stand 24 hours before applying the first coat of color. Further operations on both body and chassis are identical with those given in connection with painting and finishing them under the systems already described, and are all-sufficient to give about the worst possible looking surface an appearance of which almost any automobile owner may well be proud.

Compact Ignition System

DETAILS OF AN IMPROVED IGNITER A NOVEL FEATURE OF WHICH IS THE COMBINATION OF A SPARK COIL, DISTRIBUTOR AND CONTACT-MAKER IN A SINGLE UNIT

COMPACTNESS is not a virtue to be sneezed at in any of the automobile walks; there is a tendency to disregard this condition in ignition work and it leads to a certain discommoding complication that is more annoying than even more serious happenings, considering the bearing of the average autoist and the fact that electrical equipment is mysterious to him. The B. & S. ignition system, made by Briggs & Stratton Company, of Milwaukee, Wis., is worthy of discussion on the ground of compactness, and other features that lend facility to the plan.

The novel feature of this device is the combination of a spark coil, distributor and contact-maker in a single unit, the entire outfit being contained in a heat, moisture and dustproof metal case only 3 1-2 inches in diameter and 5 inches high.

A single non-vibrator coil is used for any number of cylinders; the coil is enclosed in a heat-proof composition case with bronze spindles at each end and revolves within the outer casing, forming its own distributor, the high tension current passing through segments in the hard rubber distributor block to the secondary terminals.

The circuit is closed and broken by means of a mechanical device, which at certain speeds is assisted in its operation by the magnetism of the spark coil.

The current furnished by six dry cells or a six-volt storage battery is utilized to produce a single spark of intense heat and volume to ignite each cylinder charge.

The igniter is designed to be mounted rigidly on the engine base or supported by a bracket provided for that purpose and the drive obtained from the shaft ordinarily provided for the timer or distributor. The top plate only is shifted for spark advance, therefore secondary wires are not disturbed. A ball and socket joint is provided for connection to spark advance lever, and the spark advance can be arranged to work from any side. The wiring is very simple, the high-tension wires leading directly from the igniter to the spark plugs and two wires from igniter to the switch, one wire from switch to battery.

The secondary terminals are screwed firmly into recesses in the distributor block, making it impossible to short-circuit the distributor with any amount of water. The cover of the igniter may be removed for inspection of contact maker without disturbing any of the wires and is also absolutely water-tight.

Three types of switches are furnished—one providing for two sets of batteries, another for battery and open circuit type of magneto and the third for battery and closed circuit type of magneto. All types are inclosed in a metal case and contain the condenser. Only the switch lever and the flange are exposed, the body of the switch extending directly through the dash, all connections being made at the rear. The lever may be operated either with the foot or by hand.

There are but two moving parts in the contact maker, which is one of the main features of the 1911 model of this igniter—the contact arm and a cam provided with a number of points corresponding to the number of cylinders to be used. In the accompanying illustrations, Figs. 1 and 2 illustrate the operation which up to this point is nothing more than a simple cam and lever contact maker. The lever *B* rests normally in the path of the cam *A*; this cam in its rotation engages the lever, causing the contact points *C* to be brought together, the points being separated by the spring attached to the lever *B* as the cam continues in its rotation.

The use of an entirely new principle in connection with the cam and lever contact maker has been made possible by the peculiar construction of this igniter—the breaker is made to provide a fixed duration of contact regardless of motor speed, and it is impossible for the motor to stop in such a position as to leave the circuit closed. Another feature is that the transformer coil itself is carried in the rotor of the igniter and is so placed that the core of coil rests directly in a vertical line with the cam of the contact maker. In Fig. 4 *H* represents the iron core of the transformer coil carried in the rotor of the igniter. The cam *A* is secured to the plunger *F*, which has a flat head, coming near to the core of the coil. The cam and plunger are so mounted in the driving spindle as to be free to slide up and down in the slots which serve as guides. They are, however, held against the upper

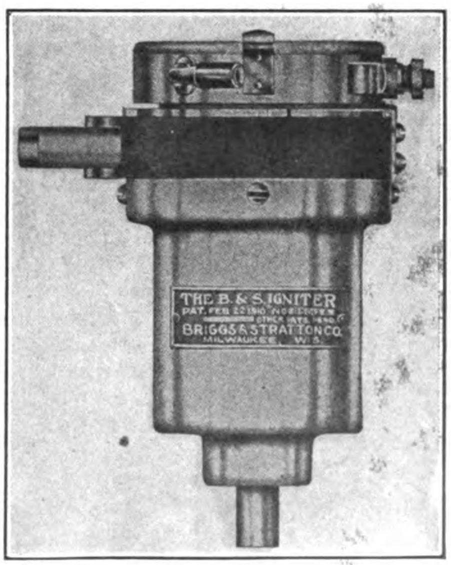

Fig. 5—The igniter as it appears ready to be put in place

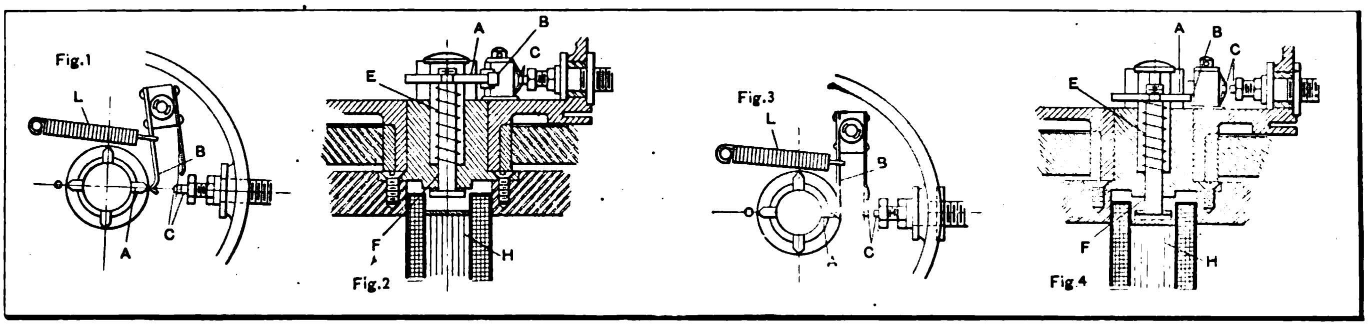
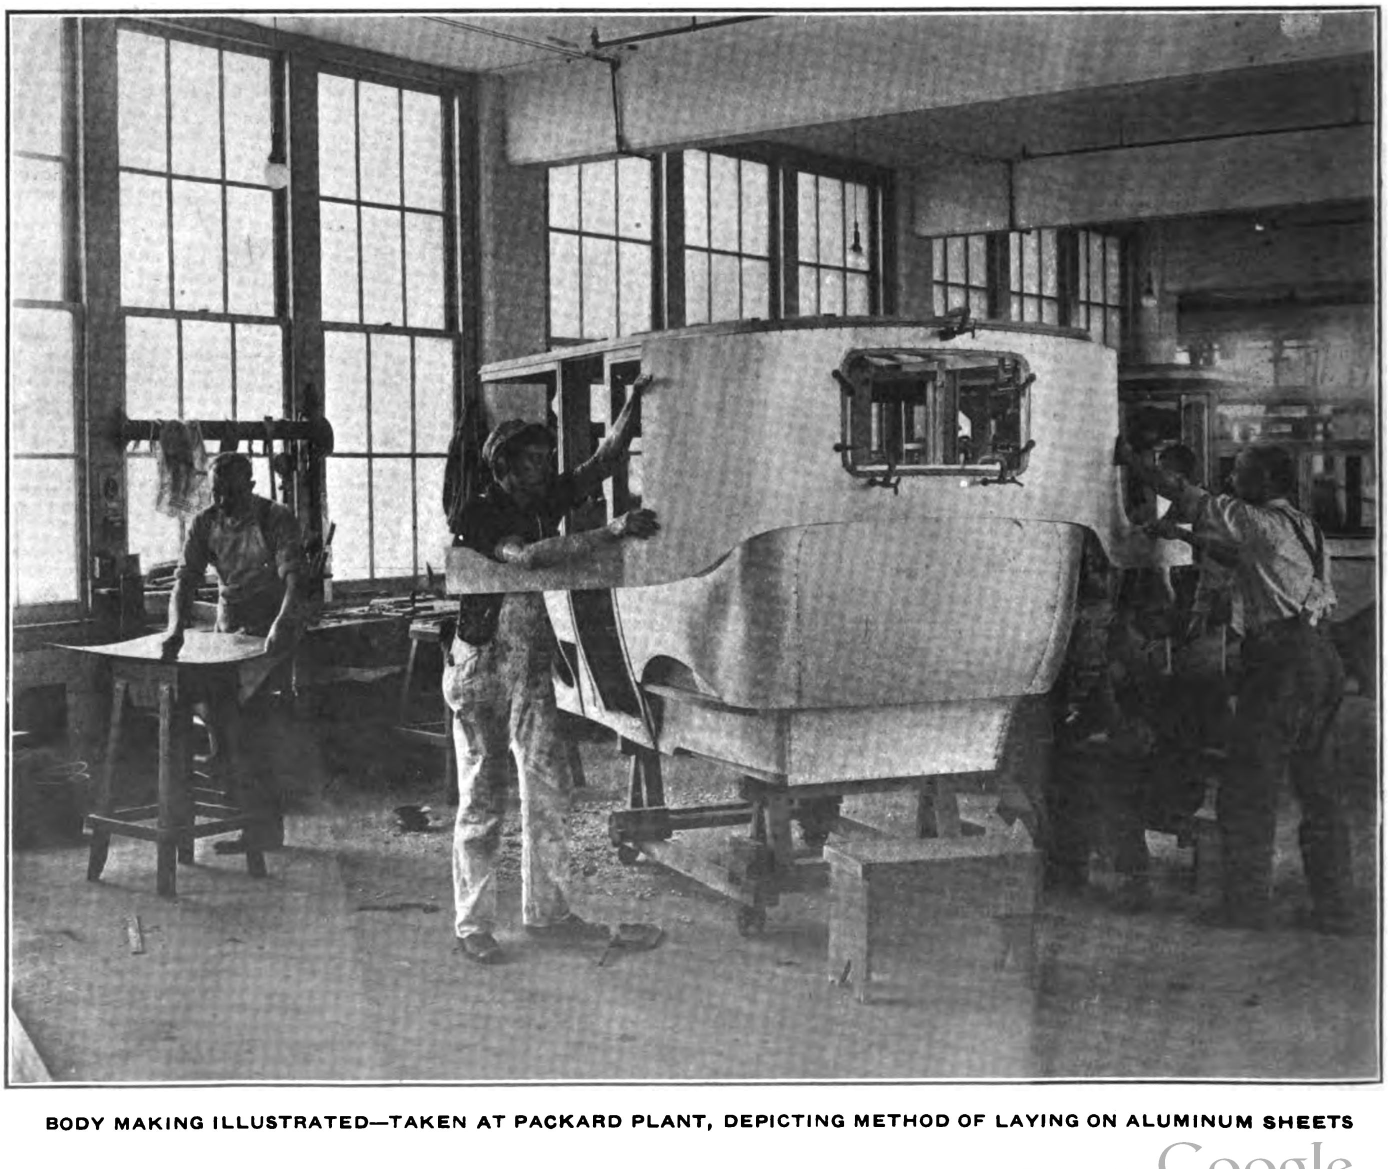


Figs. 1, 2, 3, and 4—Illustrating operation of the B. & S. Igniter, Model 10

limit with the cam in the plane of the contact arm *B*, by the spring *E*. With the cam *A* in its normal position in the plane of the arm *B*, rotation of the cam causes the contact points *C* to press together and separate, and without other provision the duration of contact of these points would, of course, vary with the speed of the motor. With this breaker, however, the instant the contact points *C* are brought together, the current passing through the primary winding causes the core of the coil to become magnetized, thus attracting the plunger *F* and drawing it instantly from its normal position. The contact arm is then retracted by the spring *L* pulling the arm over the top of the cam as shown in Figs 3 and 4. The instant the circuit is broken the cam is free to return to its normal position by the action of the spring *E*, provided it has passed in its rotation from beneath the hook. In the event that the motor stops at the instant the contact points *C* are brought together, it is obvious that the magnetic action of the coil will draw the cam from its normal position and the contact arm will be pulled over the top of the cam, thus making it impossible to close the circuit until the cam is rotated by starting the engine. At high speeds, the duration of contact is so short that the magnetic action does not have an opportunity to work. It is, therefore, effective only at low speeds when the duration of contact would be so long as to be wasteful of current, and the balance of the transformer coil disturbed. Hence the spring *E* is required to do no work except at low speeds, while at high speeds the only spring in action is the one marked *L*, and this works only between very small limits.

The construction is such that rotation of the shaft backward will produce no spark, although the company will furnish on special order for two-cycle engines a contact-maker of the same type that will operate in either direction. The igniter, as it appears ready for adjustment, is shown in Fig. 5.



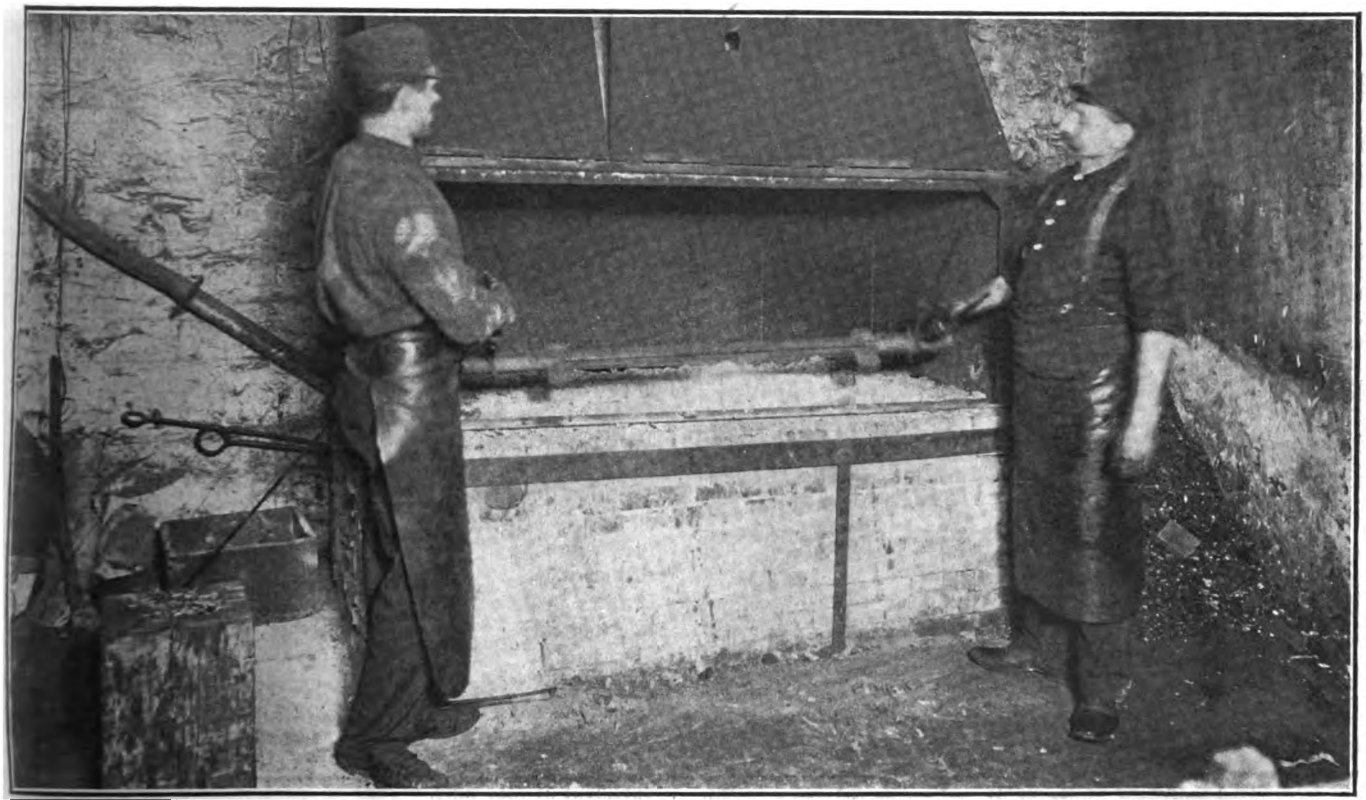
BODY MAKING ILLUSTRATED—TAKEN AT PACKARD PLANT, DEPICTING METHOD OF LAYING ON ALUMINUM SHEETS

Among the Makers

VALUE OF DROP FORGINGS; MARMON AUTOMOBILES FOR 1911; AMERICAN 1911 PLANS; A NEW TYPE OF WOODEN WHEELS; COMMUNICATIONS

THIS year brings notice of refinement that was beyond the dream of the little band of men who first introduced the automobile to a then reluctant and much-scattered clientèle. It will be remembered that when automobiles were first designed the foundry was a very important place, and the maker of patterns in wood was the dictator of progress. But the reason why wooden patterns preceded castings and the latter were utilized was because the procuring of forgings in the shapes required was at a cost that could not be tolerated, moreover it was a long road from the practices in drop forging plants of that time to what the makers of automobiles really had an eye upon.

Gradually the drop forging plants expanded; slowly the sizes of forgings that could be made were increased, and finally the [illegible] ing steel and stamping shapes came into vogue. [illegible] e the quality of steel had to be coped with; the [illegible] drop forgings and for pressed-steel parts must [illegible] characteristics. Even when the material is of [illegible] le grade it deteriorates under the hammer or [illegible] drop forged, unless subsequently treated; *i. e.*, [illegible] s are shaped it is necessary to "correct" them. [illegible] treatment is usually conducted in the form of an [illegible]. It was originally supposed that the forgings [illegible] heat-treated at the drop forging plants; this [illegible] ed out to some extent. The importance of the [illegible] es ultimately reached such proportions that the [illegible] akers of automobiles evidently reached the con[illegible] uld be better to fit out for the work and make it a [illegible] ess in their own plants.

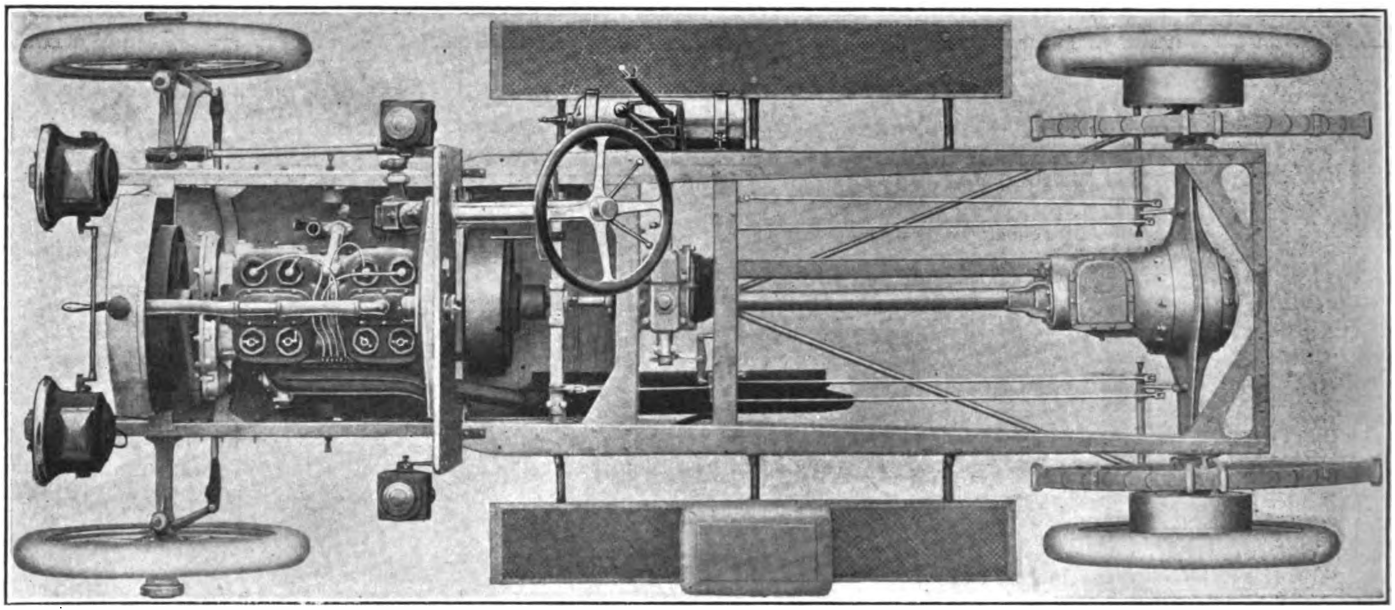


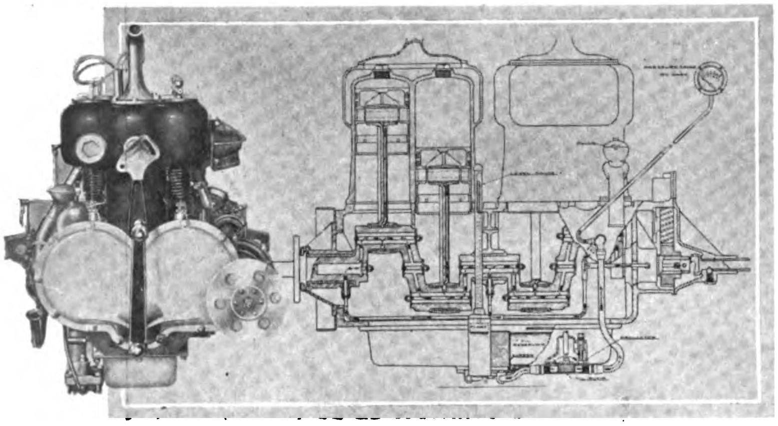
[illegible] A DROP-FORGED SPECIAL STEEL I-SECTION AXLE IN A MOLTEN SALT BATH—WOODS ELECTRIC

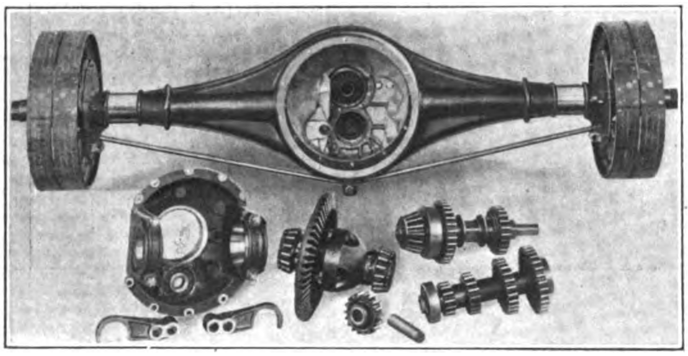
The [illegible] on here given shows one of the most approved ways of [illegible] ing forgings in order to induce in them the original kinetic qualities of the material. In this process the parts are submerged in a molten bath of chloride of sodium and barium in such proportions as will afford the right annealing temperature. The proportions of the salts may be varied over broad ranges, and they are rendered molten by passing an alternate current of electricity through the mass. A pair of iron electrodes are first used; when the salts melt the current of electricity penetrates the mass and the temperature is maintained at a constant level. Any desired temperature can be maintained; true, the proportions of the salts must be regulated to accord with the range of temperature demanded by the character of the work.

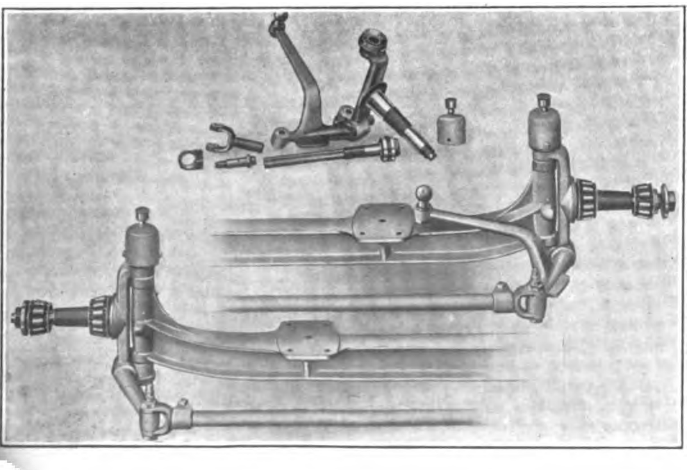
The strength of a drop forging before it is annealed is far below the original strength of the material used in making the forging, and, unfortunately, the forging labors under internal stresses that render it unsafe. Castings, to quite a little extent, have this undesirable property, and this, together with the low strength, generally, of castings, constitutes the reason for desiring to substitute forgings instead. But if the forgings are not annealed and they have, in consequence, the same faults there is nothing to be gained by adopting them.

In many of the plants this heat treatment question is extended to a point where all the steel used is manipulated, and to some extent this plan is made to serve for the purpose of reducing the number of brands of steel that are used in the cars. It is claimed that, by heat treating, it is possible to accentuate the qualities of steel in the several directions; if the parts are to be glass hard they are rendered so; if they are to be soft, they are made soft; likewise they may be brought to some intermediate state that will more or less represent some one of the infinite varieties that lie between the two border lands.









Marmon Presents '11 Li

RACING experience is telling the Nordyke & Marmon Company, Indianapolis, Ind., what it has to do to make its automobiles stand up to the work that has to be done by an automobile to render it thoroughly serviceable when it is placed in the hands of the ordinary user. When a bridge is built the engineers introduce what is termed a "factor of safety," but it must be remembered that a considerable number of bridges fell down before the engineers were able to understand just what constituted this "factor of safety." True, it was the idea of the designers of bridges to make the structure twenty times as strong as it would have to be to just stand up under the greatest possible load that it would be called upon to bear. A thousand unknown quantities intervened, hiding the light of understanding, and it was experience, in the long run, that helped the engineers to arrive at safe conclusions.

That the Nordyke & Marmon Company realized that it was necessary to get experience is shown by the tenacity with which it has pursued the strenuous life. The concern was founded in 1851; it built machinery up to 1905 and organized its automobile department at that time.

For 1911 the output of the company in the line of automobiles will consist of one general design, the motor being rated at 32-40 horsepower. The general design of the Marmon model of 1910 will be adhered to. Few changes of moment were found to be desirable. The most important, perhaps, is the lengthening of the wheelbase to 120 inches. The longest wheelbase for last year's Marmon was 116 inches—this was in the Model 32. The tread is 56 1-2 inches. With one model only, in which every effort is concentrated, it remains to afford to the clientèle of the company a variety of body options which are best described by illustrating from photographs.

What the Power Plant Looks Like with Accessories

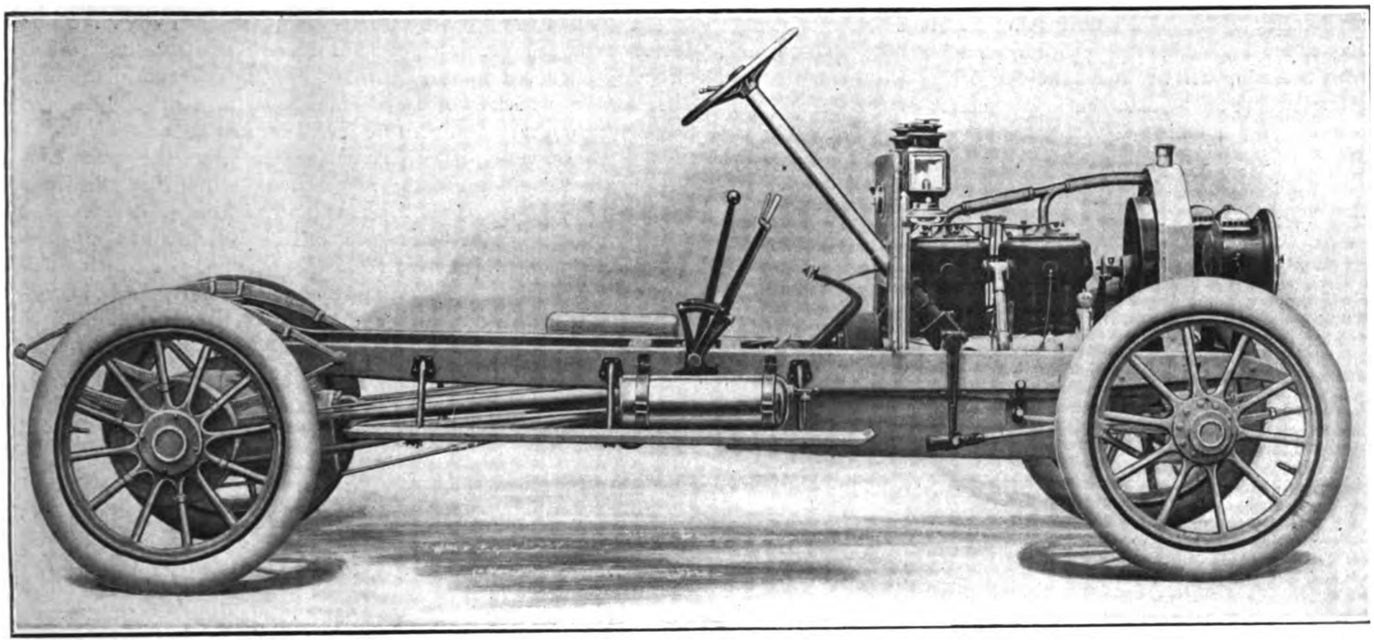
The disposition of the power plant is shown in Fig. 1, which is a plan of the chassis, and amplified in Fig. 5, which is a side

Fig. 1—Marmon chassis plan view

Fig. 2—Marmon "Thirty-two" motor, front view

Fig. 3—Rear system show how differential and transmission gears are removed and replaced through rear of axle housing

Fig. 4—Front axle; weight is carried on ball thrust bearings



REFINED LIVE REAR AXLE; EXCELLENCE OF THE MOTOR; SUBSTANTIAL FRONT AXLE; LUBRICATION MUCH REFINED; COMPREHENSIVE LINE OF BODIES

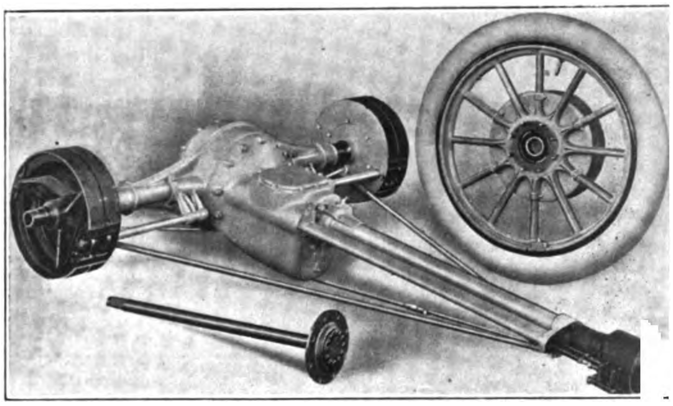
view of the chassis. Fig. 2 is an end view of the motor at the left and a section of the same at the right. Fig. 7 presents right-hand side of motor and Fig. 8 the left-hand side.

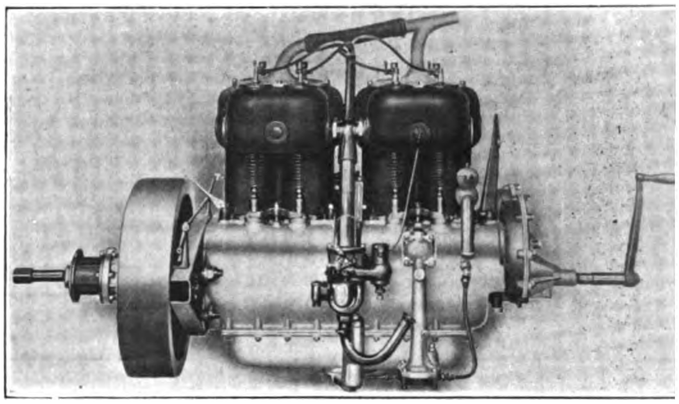
The motor has four cylinders with a bore of 4 1-2 and a stroke of 5 inches. The cylinders are cast in pairs, work four-cycle and are water-cooled. The right-hand side of the motor as presented in Fig. 7 gives the position of the carbureter, to which is attached a one-piece vertical member through which the carbureted air passes to a point between the two pairs of cylinders, which in turn are so designed that the mixture enters transfer ports from the carbureter standpipe, thus eliminating the customary horizontal portion of standpipe construction.

Fig. 8 shows the magneto resting on an extension of the upper half of the case driven by an extension shaft from the water pump, thus bringing the pump and magneto in common shaft alignment, but with a view to ease of installation and practicability in performance a universal joint is placed not only between the magneto and the pump, but also between the pump and the pinion by means of which the shaft is rotated.

The clutch is of the cone type, is nested within the flywheel confines, and the clutch mechanism, including the spring, is enclosed in a protecting housing. By glancing at the chassis plan in Fig. 1 an idea of the compactness of the clutch mechanism will be gleaned, and it will be there observed that a tumble shaft with square ends intervenes between the extremity of the clutching mechanism and the universal joint housing which is supported on a stout cross bar.

The power as it is transmitted through the clutch and tumble shaft to the propeller shaft within the tube is taken up and passed along to the transmission gear, which is a unit with the live rear axle. A general view of this unit is shown in Fig. 6, but a better understanding of the details of design will come from studying Fig. 3. In this it will be observed that a unit plan of assembling is brought into play. The differential gears of the bevel type are shown in a housing to which is attached the





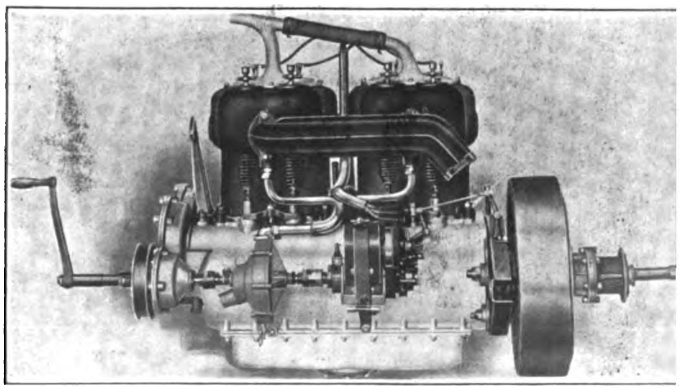


Fig. 5—Marmon chassis, intake side

Fig. 6—Marmon rear system showing brakes and speed gear change box attached to axle housing

Fig. 7—Marmon "Thirty-two" motor, intake side

Fig. 8—Marmon motor showing exhaust side and magneto

large beveled gear, and conical roller bearings are mounted in place on the two ends of the differential housing. To the left of this assembly will be found the supporting grid, which is also contrived to accommodate the bearing back of the bevel pinion on the end of the main shaft of the sliding-gear system. The lay shaft of this system is also in view, and through the good office of the supporting grid, considering the methods of design, the entire aggregation may be assembled independent of the axle housing, after which they may be thrust into place with the assurance that they will be in proper alignment and so related to each other that the intended functions will be performed noiselessly and well.

Lubrication and the scheme of execution will be better understood by examining the section in Fig. 2, which shows a drilled-out crankshaft to which oil is fed under pressure by means of a force pump that is incorporated into the lower half of the crank-case. The oil well is located in the lower half; means are at hand for filtering the oil and the arrangement of piping and ducts is with the view of forcing a continuous stream of oil up through the crankshaft to the connecting rod bearings, thence along the connecting rods to the gudgeon pins, and finally to the cylinder walls. In like manner the main bearings are kept in a flooded condition and means are at hand to take care of the excesses of lubricating oil, all of which finally returns to the oil well in the lower half of the crank-case, properly lubricated and in fettle to begin another cycle.

The front axle design and the attending details are shown in Fig. 4. The axle is of the I-section, liberally proportioned for the work, and the knuckle bearings are especially long, with means for lubrication. Conical roller bearings are used, and besides affording the means of adjustment to take up shake, they are securely locked into place by means of well-designed locking nuts. The steering arm is of stout build, with a large spherical joint, and the details throughout are in keeping with the best practice.

The transmission gear is three-speed selective, with the side levers arranged for a right-hand drive. The steering post is properly anchored to the dash, is given an agreeable rake, and the steering wheel is of large diameter with a properly shaped rim with the spark and throttle levers located above.

The chassis frame is of channel section steel; the spring suspension is full-elliptic at the rear and half-elliptic at the front. The details of the chassis construction are worthy of more than passing notice. At the point of narrowing at the front the flanges are wide, and there are two cross bars coming close to the universal joint so that the lateral strength of the frame is in fullest keeping with the requirement. The flanging narrows toward the back, but large gusset plates are used to tie in the rear cross bar. Trunnions are provided and fastened to the side bars near the rear cross bar by means of which the full-elliptic springs are free to swing by them in response to the motions induced by road inequalities. There is an entire absence of castings on the chassis; pressed steel is utilized as brackets for the footboards and at such other points as experience dictates. From the center cross member forward, the side members have a drop flange to which the mud pan is secured with spring clips accessible from the sides.

If the power plant and the methods of its installation and control may be regarded as representative of the latest Marmon practice, it will greatly facilitate matters along this line to point out that the brakes and the various other means of controlling the road performance of the car are also adequately cared for. Fig. 6 shows the two pairs of internally expanding brake shoes placed side by side upon the axle member; the drums are of large diameter and the shoes are wide, so that the pressure per unit of area as it comes upon the friction bands is kept within the limit, having in view the fact that the best braking performance follows when a fabric is used, if the same is fireproof, and the speed of rotation is substantially that which obtains with road wheels.

Among the several types of bodies offered, the closed-front, for the five-passenger touring car, is especially notable, its straight-line effect appealing strongly to the taste of the critical. A similar body, somewhat shorter, is offered for those desiring a four-passenger toy tonneau effect. This car is offered in an open-front body also, while landaulets, limousines and coupés are built to order. A smart roadster, with gasoline tank, trunk and tire rack at the rear of the seats, is offered with the regular line.

The brakes are very large, effective, durable and absolutely dust-proof, with the most convenient adjustments. Quick detachable rims and 34 x 4 tires are standard, with an option of 32 x 4. One adjusting nut takes up all the play in the irreversible steering gear, an 18-inch wheel insuring ease and comfort in steering.

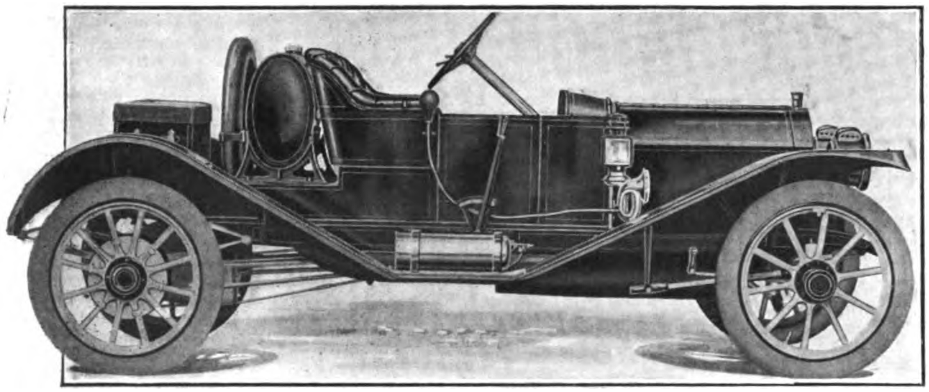

Fig. 11—Marmon "Thirty-two" roadster. Regular equipment as shown except the extra tire

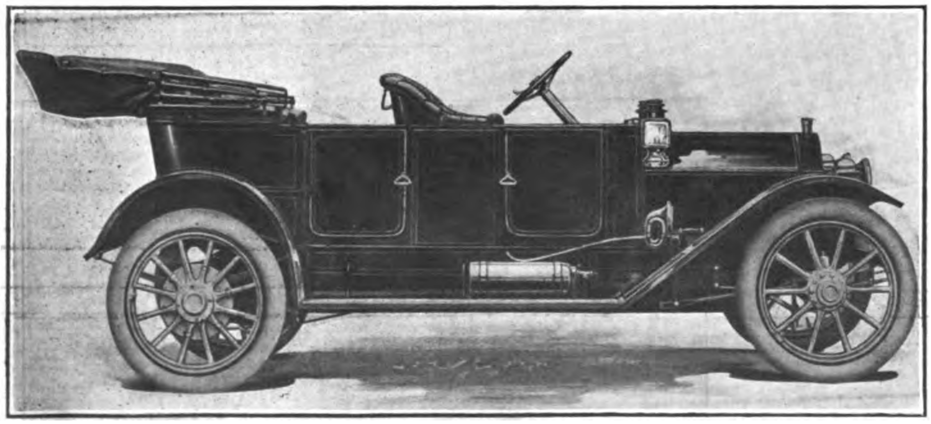

Fig. 12—Marmon "Thirty-two" five-passenger touring car

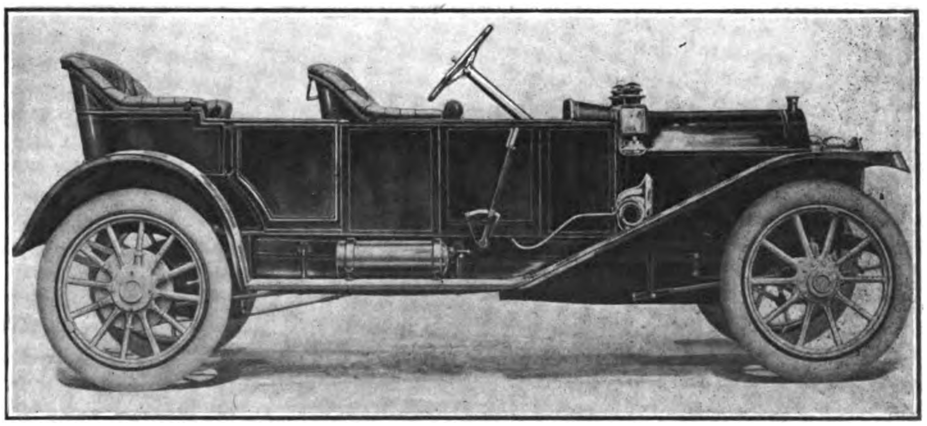

Fig. 9—Marmon "Thirty-two" four-passenger suburban

The easy-riding qualities for which the Marmon has always been noted are maintained by the use of well-proportioned full elliptic rear springs and semi-elliptic front springs.

Bodies are made of special perfected cast aluminum with sheet metal seat backs. Blue black with gray striping is the standard color scheme, although any other combination may be ordered. The upholstering is marked by the best of workmanship, only the best of genuine leather being used, with leather welts and binding. Spring backs, spring edge cushions, white curled hair piled, and clinch tufting buttons are used.

The fenders are of neat and graceful design, substantially made of sheet steel. They are enclosed next to the body, both front and rear and have outside flanged edges. The steps or running boards are of cast aluminum with neat pyramid surface and metal guards close the space back of the steps from the front to the rear fenders, thus confining the rush of air and carrying the dust far to the rear.

CARS AS OFFERED FOR 1911

Clutch	TRANSMISSION				Wheelbase	Tread	Frame	BEARINGS			Weight	TIRES

Front axle assembly, presenting an I-section axle with a drop center, long knuckle bearings, means for lubrication, and refinements

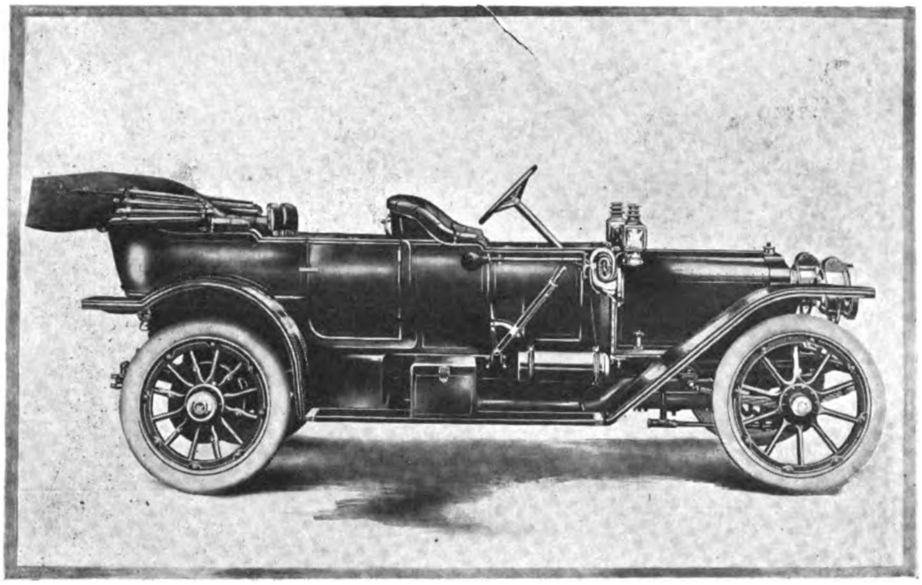
ADVICES from the American Motor Car Manufacturing Company, of Indianapolis, Ind., continue to indicate that the products of this make are holding the interest of a large and growing clientèle; the underslung scheme of design continues to make staunch friends, and large diameter road wheels assure easy riding under severe road conditions, with the further advantage of accentuated tire life. The remaining conditions for harmony are in the form of a long wheelbase, well-balanced weight distribution and ample power. The line of cars is somewhat extended, and in many ways the mechanical details are brought up to a higher state of perfection.

Reserve power has always been the starting point of the designers of this company, and the 1911 motors have been specially designed to bear out the reputation for high efficiency in this respect that the company's product has always borne.

The advantages of the underslung frame are obvious, for besides the minimizing of the tendency to side slip and rear lash at high speeds, a perfectly true straight-line drive is made possible and the occupants assured immunity from harm in the event of a front spring breaking. To these advantages must be added the low center of gravity, which decreases the possibility of turning over almost to the vanishing point.

Of the nine models which will be standard during the coming year the Roadster Special, the Speedster and the Traveler Special are equipped with motors developing 52.9 horsepower A.L.A.M. rating, while the Roadster, Roadster Coupé, Traveler, Traveler Coupé, Tourist and Limousine are all driven by 46.2-horsepower engines.

The Roadster and Speedster types are all two-passenger bodies; the Travelers, with the exception of the coupé, are five-passenger propositions (the latter carrying but four), while the Tourist and the Limousine each has a seating capacity of seven. All the Roadster and Speedster chassis have 112-inch wheel base, the other models measuring 124 inches in this particular—the tread



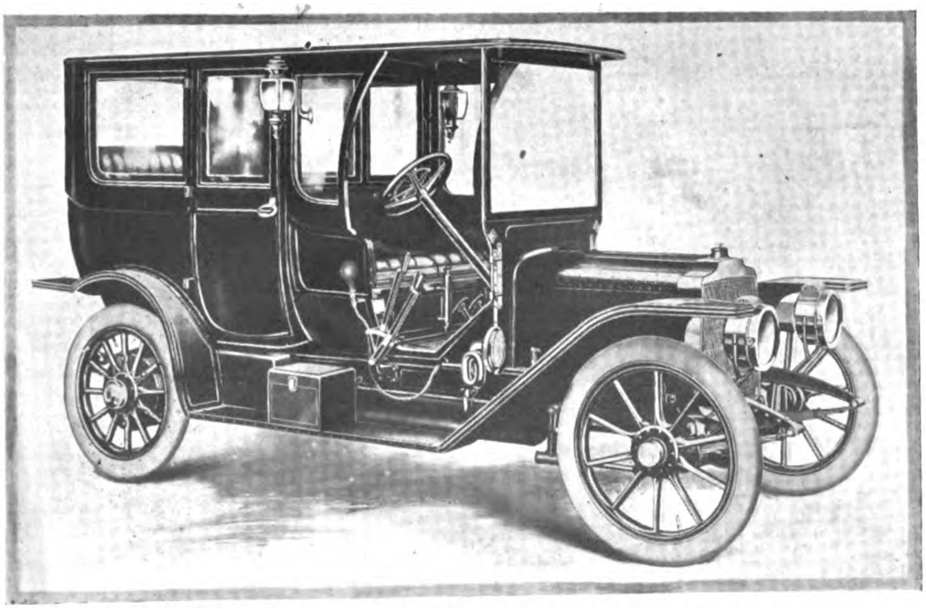
Fore-door type of "American" Tourist

in all models being uniformly 56 inches. The weight of the several types varies from 2,600 pounds in the Roadster Special to 3,600 pounds in the larger cars.

Considerable experience on the road has added stability to the contention that the weight question is on a basis of great stability.

Mechanical Features Brought to a High State

One of the principal objects in utilizing the underslung idea, coupled with a long wheel-base, is to attain perfection under severe road conditions. The center of gravity of the car is brought as close to the ground as possible in order that the turning over speed will be maximum. The factor of safety from the autoist's point of view lies in the difference between the speed at which the car travels and the speed at which it will turn over. This factor of safety is definitely established in this car. With a fixed tread, which is one of the conditions that every automobile must conform to, the turning over speed increases as the center of gravity is lowered. The American Motor Car Company, of Indianapolis, Ind., points out in its literature that the factor of driving safety will be 100 per cent. when the autoist is traveling at 42 miles per hour on a curve with a radius of 571 feet. This is the same as saying that safety terminates when the car is going 84 miles per hour around a curve the radius of which is 571 feet. Of course, it is not recommended that autoists should force the speed up to 84 miles per hour, but it is worth something to know just what the safe limit is.



"American" Limousine

Having in view the necessity of a low center of gravity and the appending conditions, the mechanical equipment of the American cars is along lines consistent with the engineering aim. The motor is identical in the five models, having four cylinders, 5 3-8 x 5 1-2 inches bore and stroke, respectively, cast in pairs, working four-cycle water-cooled. The remaining models are fitted with a larger motor. Lubrication is positive utilizing a pump for circulation. The power is transmitted from the motor through a leather-faced cone clutch of proven proportions to a selective type transmission with four speeds, the same being located amidships on the frame. From the transmission to the live rear axle a shaft drive is used. The wheelbase is 112 inches in the Roadster, Roadster Special, Coupé and Speedster. In the Tourist model, however, the wheelbase is 124 inches, and this length obtains in the Traveler Special, Traveler Coupé, Tourist and Limousine. The tread is 56 inches in each case; pressed-steel side frames are used in all models. The bearing situation is adequately cared for through the good office of three plain bearings on each crankshaft, ball bearings are in the transmission system and throughout the axles. It is pointed out that the weight of the respective models is fixed with a view to good road performance and economy. If a car is too light there will not be sufficient traction and the tires will be worn out by slippage, but if the weight is excessive the tires will be disrupted. Fixing the weight, then, is regarded as an engineering situation of no mean purport.

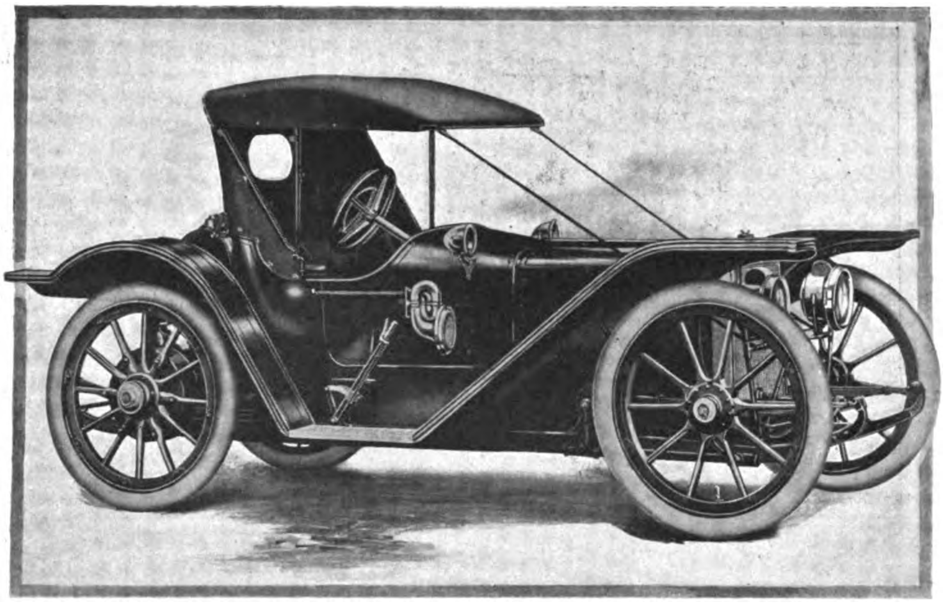
Limousine......	5250	46.2	Limous.	7	4	5⅜	5½	Pairs..	Tubular.	Cent'fl...	Bosch..	Storage..

The tires used are especially large, they being 40 x 4-inch front and rear on the Roadster, 36 x 4-inch front and 36 x 5-inch rear on the Roadster Special, which size obtains with slight variation on three models, while the 40-inch diameter tire holds sway on four of the models.

The motor has two arms extending out from the upper half as depicted in the illustration of the left-hand side of the motor; the magneto M_1 is placed on a shelf that is cast integral with the top half



"American" Torpedo Roadster

also and the drive for the magneto is the same as for the pump P_1 for the circulation of the cooling water. Between the pump and the half-time gear housing H_1 an Oldham joint J_1 is located; by means of this joint all details of alignment are cared for, and in the event it is desired to remove and replace the pump or the magneto, the work may be accomplished without trouble or the fear that the parts will not go back into place and serve as well as when the motor comes from the assembling room of the maker. Among the other nice details of design that show good execution is the fan F_2 for propelling of air; it is driven by a wide leather belt B_1, taking power from a shrouded pulley that is fastened to the same shaft that drives the pump and magneto. The flywheel F_1 is of large diameter and sufficient width to assure an adequacy of flywheel effect; this is a necessity for a well-behaved, sweet-running motor. The lubricating oil is contained in the round oil holder O_1 which is seen between the two pairs of cylinders.

Glancing at the right-hand side of the motor it shows the Stromberg carbureter C_4 and a manifold of good shape M_2 Just above the intake manifold is the exhaust manifold M_3. For the breather B_2 there is an adjustable cap. The lubricating oil passes through the pipe O_2 and is maintained in active circulation by means of a plum that is located in the bottom half of the case. Plates P_1 and P_2 permit of access to the bottom half from the under side for purposes of cleaning and the oil pump is so located there that it can be removed and replaced at a moment's notice.

ype

The front axle is of the I-section as shown in the title illustration. The shape is such as to afford great strength, and the knuckle bearings are large for the work with ample means for lubrication.

The steering equipment in addition to the use of a steering gear of the worm-and-sector type, with long and substantial bearings, a grease-tight case and a means for lubricating is rendered more substantial by the liberal yoke type of joints that are securely fastened to the cross and drag rods, through which steering is done. The material employed in these important members is selected with discrimination and the method employed in the fashioning of the parts is with the distinct idea of security. Instead of depending upon the ordinary keying methods at the various points in the transmission system, flanging is resorted to wherever it is possible; as an illustration of the working out of this idea, the floating axle members are flanged at the outer end and are milled around the periphery of the flanges to form integral claws that engage mates in the hubs of the wheels. At the other extremity of each floating member a fluted drive is used, and it is so designed that the floating members may be withdrawn at will. Moreover, the driving faces are on integral metal with four pressure points, whereas with a key there would be but one.

In the design of the clutch account is taken of the ills of inertia so that flywheel effect is reduced to a minimum. This is brought about by using the least possible amount of metal consistent with strength. But there is another innovation in the clutch, which takes on the form of air propeller veins, so that the clutch, in addition to serving for its normal purpose, adds its quota in the direction of keeping the motor cool. The clutch spring and the relating parts are protected by a dust-proof housing with means for introducing lubricant. The four-speed transmission gear is designed for strength, the spindles being short, and the gears of sufficiently wide face, considering the

excellence of the material, to withstand the exigencies of service during the life of the rest of the car. In the selective system the pick-up levers and yoke with guides and plungers are made into a separate unit, thus assuring perfect alignment. Provision is made for safety, it being impossible to have more than one

VERY FEW HOUSES MORTGAGED TO BUY AUTOMOBILES; WANTS A NATIONAL LICENSING LAW FOR AUTOMOBILISTS; AFFORDING THE LATEST VIEWS IN RELATION TO THE EXPEDIENCY OF OWNING AN AUTOMOBILE

The Parson's Tires and Taxes—My little study set in the peaceful frame of a country parsonage is not often the theater of revulsions against the existing order, and it is with deep consciousness of the errors to which the human mind is prone that I venture to broach a subject so essentially worldly as to lie perchance beyond the province assigned to me. I feel, however, that I must bestir myself. This turbulence must be removed from my mind before I shall be able and fit to assuage sorrows and allay tribulations among my simple and honest parishioners who have learned to look to me for remedial powers over their troubles through the grace of divine faith. Let me initiate you in the situation. Scarcely a twelve month has lapsed since my good friends tendered me, out of their good will and after careful counsel of the proprieties, a mechanical vehicle by the aid of which it was believed I might be able to reach the sick and disconsolate in need of ministration. And I have greatly appreciated this thoughtful and modern gift. It has permitted me several times to meet and speak to the elders of neighboring towns, where the pure word is seldom heard, and my hired man Benjamin, who attends to agricultural and horticultural work at the parsonage and receives a half share of the income vouchsafed me through this source, assures me that a gain not wholly immaterial may be attributed to the uninterrupted employment of two horses whose services were formerly frequently required by me for parochial visits.

As it did not appear seemly that a man of the cloth should travel with a rapidity that partakes of haughtiness and engenders resentment, my parishioners manifested no little wisdom in selecting a mechanical vehicle resembling a buggy and having four high and thin wheels. With this I am enabled to travel in becoming modesty and I notice with much satisfaction that the dust, which unfortunately lies thick over our country thoroughfares, lanes and causeways, does not rise in opaque and rolling clouds following my progress and heralding my arrival.

For the quiet errands of mercy in which my friends particularly intended this vehicle to become instrumental, the rush and roar which, as I have occasion to observe, usually attend the employment of mechanical locomotion on our roads, would seem to be poorly in accordance with the command that thy left hand shall not know what thy right hand is doing.

I come now to that which has perturbed me. A printed notice was sent to me through the mail ordering me to forward the amount of the "automobile tax" duly and lawfully levied against me by reason of my possession of the mechanical vehicle above referred to, and I have taken pains to ascertain by careful inquiry that the amount which I am required by law to pay into the treasury of the commonwealth is exactly equal to the amount assessed against owners of vehicles which are equipped with large and thick tires and which, as I have personally observed, are enabled by means of these tires to travel, with comfort to their occupants and discomfort to others, at high speed. It was told me, and I have since verified this contention by correspondence with competent authorities on the questions of fact, that the chief reason which induced our legislators to impose a special financial burden upon the owners of mechanical vehicles resided in recognition of the injury done to all roads when mechanical vehicles are driven over them at high speed, it being needful to repair such injury and to levy taxes for defraying the expense of the repairs upon the taxpayers at large. My authorities inform me also, however, that the high speed which may be said to be potentially present in high motive power is never released in practice, unless such release may be indulged without discomfort to those seated in the vehicle. and that broad air-filled tires constitute the only known and practicable means by which discomfort at high speed may be effectually removed and, indeed, turned into an exhilaration of almost intoxicating powers over the human mind. Refraining from all comment to which I might be tempted, I quote these statements almost in the words of my legal informant.

Having been reared to apply logical processes in reasoning about the affairs of the world, while taking reason captive under the obedience of the faith in those greater things which transcend all comprehension, I am now moved to direct to you this earnest inquiry: Should not, in true justice, the taxes which are now levied upon mechanical vehicles and against the owners of such be levied, instead, upon rubber tires of the description known as pneumatic, from being intended to be filled with compressed air, and should not the amount of such tax be regulated according to the size and width of these air-filled tires?

In the comparative seclusion of my work and calling, the broad round tire, fat, rotund, as it comes bounding and swaying and softly undulating curves out of a cloud of the fine white powder of the macadam or from the murky effervescence of the country road, has come to be to me as an offensive symbol, not of mere opulence which is the distribution of Providence for ends we know not, but of a heathenish voluptuosity which recks little of aught but its own satisfactions. Believe me, I do not wish to entertain this turbulent bitterness, and I feel it should be possible to divorce it from my views by communicating with those who know the subject most intimately. Anticipating that the light which I confidently hope will reach me through your columns will cause a radical revision of my present standpoint with regard to tires and taxes, I would ask you to kindly omit my name if you allow me space for this letter in your valuable periodical.

Extravagance and Luxury vs. Economy and Necessity.—The telephone to-day is seldom classed as an extravagance and rarely as a luxury; on the contrary it is an economy and a necessity under modern conditions. The railway train and the electric car have also become necessities and are now recognized as economies if time is indeed a consideration. The argument that these modern means of transportation encourage more travel and the expenditure of a greater amount of money in traveling is refuted by the fact that in effect they reduce distance and save time, making possible undertakings otherwise impracticable.

Mayor Gaynor, of New York, said in a recent statement that the use of the motor car had increased the capacity of city streets six-fold over that of horse-drawn vehicles, which can be further reckoned as a saving of five-sixths of the time, an equivalent of reducing the distance to one-sixth. Would not travel by motor car be economy even with the mileage cost as great as by other means, notwithstanding the fact that the ease in traveling and the saving of time might induce an increase in travel?

It cannot be disputed that the motor car has greatly increased property values, making accessible remote localities, bringing the city to the farm, and the farmer to the markets. It encourages more time being spent in pure air by those confined to offices under the great pressure of modern business, and is of far greater benefit to the owner and his family than would be the annual interest on the same amount at 3 or 4 per cent. It would be quite as reasonable and practical to consider abandoning the electric car to return to the horse car, or giving up the steam railroad car to return to the prairie schooner, as to abandon the motor car.

It would be difficult to conceive of a banker refusing to make a loan on a responsible business merely on the ground that some portion of this money might be exchanged for an article which has astonished the world on account of the practical way in which it has effected a marked saving of time, being the equivalent of reducing distance. It is perfectly true perhaps that men have been known to mortgage their homes or to borrow on life insurance policies to buy machines, and as an indication of reckless extravagance and shiftless foolishness such a performance is to be deprecated, but there is no logic in blaming the automobile maker or denouncing his business as the cause of a silly act.

As a matter of fact there is less of this going on than some critics would have the public believe. A farm located an hour from the market, reckoned on the basis of horse travel, can be brought so much nearer in effect by the saving in a practical way of two-thirds of the time necessary to travel the distance, and why should the privilege be refused, or the farmer censured for employing a modern agent of economy any more than for the use of the modern self-binder in the harvesting of his grain. He is not criticised if he places a mortgage on his farm in order to purchase advanced equipment to carry on his work.

Unofficial statistics have been obtained which are interesting for they indicate that a possible 75 per cent. of the motor cars purchased are bought by those who have previously owned private conveyances, or are using the former in a commercial or semi-commercial way; it has also been shown that the wealthy almost invariably buy expensive cars and more than one car, and on a fair estimate 85 per cent. of the money invested in automobiles is expended by this class.—Harold O. Smith, president Premier Motor Manufacturing Company.

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL CLIMBS, ETC.

Dec. 1............Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Dec. 31-Jan. 7, '11.New York City, Grand Central Palace, Eleventh Annual International Automobile Show.
Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Manufacturers.
Jan. 16-21, 1911..New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4, '11.Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories, Exclusively.
Feb. 6-Feb. 11, '11.Chicago Coliseum, Tenth National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.
Mch. 4-11, 1911...Boston, Mechanics' Building, Ninth Annual Show, Licensed Automobile Dealers' Association.

Races, Hill-Climbs, Etc.

Sept. 5-10........Minneapolis, Minn., Track Meet at State Fair.
Sept. 7-10........Buffalo, N. Y., Reliability Run, A. C. of Buffalo.
Sept. 9-10........Providence, R. I., Track Meet.
Sept. 10..........Los Angeles, Cal., Mount Baldy Road Race.
Sept. 10..........San Francisco, Cal., Golden Gate Park Road Race, Automobile Club of San Francisco.
Sept. 10-12.......Catskill Reliability Contest and Hill Climb, Motor Contest Association.
Sept. 10-12.......Seattle, Wash., Race Meet.
Sept. 15..........Algonquin, Ill., Annual Hill Climb of Chicago Motor Club.
Sept. 16-26.......Asbury Park, N. J., Aviation Meet, Aero Club of America.
Sept. 17..........Syracuse, N. Y., Track Meet of Automobile Club of Syracuse, Syracuse Automobile Dealers' Association and the New York State Fair Association.
Sept. 24..........Belmont Track, Narberth Race Meet, Norristown Automobile Club.
Sept., middle of...Chicago, Commercial Car Reliability Contest of Chicago Automobile Club.

Foreign Shows and Races

May 1-Oct. 1....Vienna, Austria-Hungary, Automobile and Aviation Exposition.
Aug. 1-Sept. 15...French Industrial Vehicle Trials.
Oct. 15-Nov. 2....Paris, France, Aeronautical Society Show.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

RACING, if it is classed as a sport, interests the supporting public in one way if it is clean sport, and in quite another way if it is conducted on a scurvy basis.

* * *

THE better class of citizen wants clean sport, and is for the square deal. This character of man can be taken in once simply because his natural inference is that a sporting event will be conducted in a clean way, for he assumes that men are sane, and he knows that it is suicidal to conduct a sporting event otherwise than on a clean basis.

* * *

THE other class of citizen, of which America has mighty few, is out for the dollar, and he doesn't care a hang whether he gets a clean one or not. It is this class of man that provides first-class material for the making of a "short-change" artist—he permeates every grade of society, and the automobile industry has seen enough of him.

* * *

HOW to get rid of the alleged sport, or, better yet, the "blackleg," is a serious problem. The supporters of the automobile industry relied upon the rules as promulgated by the "Contest Board" to accomplish this considerable undertaking. Are the rules equal to the task?

RULE 78 on page 24 of the official edition as issued by the Contest Board is as follows: "78. Records—The Contest Board shall pass upon all records and may decline to accept any claim which, in its opinion, would not promote the interests of the sport.

* * *

"NO claim for a record of one mile or under and up to five miles will be considered by the Contest Board, unless the same is taken by an automatic electric or mechanical timing device approved by the Contest Board, and the actual printed evidence taken by such timing device is submitted to the Board together with the claim for the record."

* * *

IF rule 78 debars the Contest Board from accepting a claim for a record, if the same is made in the absence of an electrical or mechanical timing device, has the Contest Board any right to sanction a meet if it knows that the race is to be run in the absence of any suitable provision for carrying out the terms of the rules?

* * *

THE law says that it is a crime to commit murder. A judge passes the death sentence on a convicted murderer; would a judge have any right to help the murderer commit the crime?

* * *

CAN the Contest Board afford to sanction a race if the public is to be "taken in"? Is it not true that the public relies upon the Contest Board to protect it against unclean sport? Is it clean sport to conduct an event and put up a set of conditions that are in absolute violation of the recognized rules?

* * *

IF the Contest Board believes that an electrical or mechanical timing device is necessary in order to ascertain the real time that a car may make, how can it be claimed by anyone that an event recorded in any other way is sufficiently accurate to be worthy of serious consideration?

* * *

MANY of the best citizens who are vitally interested in the success of the automobile industry voice the sentiment which has for its foundation the fact that the racing situation is far from healthy and a detriment to the art. How can it be otherwise if races are to be sanctioned despite the fact that the conditions under which they are to be run are known beforehand to be in absolute violation of the rules?

* * *

IT was stated over the 'phone by a representative of the Contest Board to the Editor of THE AUTOMOBILE on September 6 that there would be no racing to speak of were the Board to decline to give sanctions for events that do not conform to the rules. Does the Contest Board willingly accept a position that is equivalent in every sense of the word to the foxy "bull" that is used at the slaughter house in Chicago to lure cattle to slaughter? Is the public to be treated as cattle?

Jarred Editorial Brains

DISCUSSING THE FEASIBILITY OF HAVING THE EDITOR'S BRAINS PUT IN A JAR FOR SAFEKEEPING WHILE A SELF-APPOINTED SUBSTITUTE DOES THE REST

THE advertising of locomotives in a journal devoted to dressmaking—it not being a kindred subject—litters up the pages of the paper and adds absolutely nothing of value from the subscriber's point of view—in fact, such practice insults the intelligence of the reader.

But in a paper devoted to the automobile, if advertising is confined to the subject that is kindred, it stands to reason that the subscriber is benefited to whatever extent he will be able to improve his knowledge of the subject along constructive lines. Naturally enough, the reader of the paper devoted to the automobile subject would see nothing of value in an advertisement of some grade of whiskey, no more than he would were he confronted by an advertisement of caskets and other funeral trappings.

Of course advertising is placed in a paper for remunerative reasons; certainly, the income of the paper is substantially from advertisers. But a fact is not reduced to the level of a fallacy because it is stated in the advertising pages of a paper. One more point: the paper, if it is well edited, costs more to build than is received from subscribers—considerably more.

This being true, advertising is valuable to the reader; first, on the ground that it states interesting things and relates constructive facts that the reader is interested in, and, second, it affords the means for enterprise, bringing about a condition which permits the editor to reach out and pay for matter that the reader cannot get by perusing the advertising pages.

True, a paper that publishes nothing but puffs for the advertisers offers nothing in return for the subscription price but the same character of information as will be contained in the advertising. Equally true, a paper edited along such lines is more than likely to take advertising that may not be confined to facts.

Is it the proper business of the editor of a paper to censor the material that is to be used in the paper? Take for example:

> "Wanted—A promising yeggman, who is not afraid of consequences; one who can shoot straight; a man, in fine, to be depended upon in an emergency."

In view of the brevity of advertising language it is frequently desirable to editorially comment upon the matter advertised; what comment would a self-respecting editor make were he to take up the subject as it is portrayed in the above specimen of advertising?

But if the same editor were to take an interest in some device that is briefly announced in the advertising pages of a paper that does censor the material that ultimately finds a resting place within the confines of its two covers, is he not doing the very thing that the reader pays his subscription price for? Is the advertiser receiving a special concession?

No. The editor works for the reader of the paper; he is the servant of the reader; his business is to be faithful to the subscriber. If the advertiser gets any benefit at all it is because he has the good sense to do the kind of business that is worth talking about from the reader's point of view.

On this account the paper that employs an honest servant for the subscriber becomes the best medium to advertise in. Why? Because the reader will be a man of influence and discriminating intelligence, and, what is equally to the point, the dishonest advertiser will find the other character of paper in which to expose his wares.

The value of advertising matter to the reader then depends upon the competence of the reader's servant—the editor. If the servant is faithful to his plan the reading matter in relation to the state of the art will be as good as the editor can honestly make it, and the advertiser will be of that class which, having real things to dispose of, selects the medium that commands respect.

When a man elects to purchase an automobile, whom does he consult first? The advertiser? The least intelligent person in his immediate locality? Does he send out to the newspaper stand and buy a copy of a paper devoted to banking, for instance?

Would it be too much to believe that he might ring up his respected friend, or even casual acquaintance, and say: "Hello! Is this you, Mr. Jones? Say, I'm Houseanlot; I want to buy an automobile; don't know a thing about 'em; I see you have a car; it seems to give you satisfaction; what would you do were you in my place?"

Other end of the line, "Well, I'll tell you; the car I have has done very well; it's three years old; I intend to sell it this year and then I will buy a ——— car. I see by the paper which I read that things are growing a little better from time to time, and I am able to place reliance in what my paper says; in your case, the demand will be a little different from mine; why don't you subscribe to my paper and get coached up—it will help you to judge better of the possibilities."

In all fairness, considering the situation broadly, it is scarcely to be taken for granted that advertising litters up the pages of a paper unless the advertiser clubs the editor into insensibility; in that event it of course follows that the editorial pages will be but a poor form of advertising, given as a premium by the editor who surrenders his right to think.

Would an advertiser patronize a paper that could not command the notice of readers? Not after the point is made clear. Would readers put in time perusing a paper that comes from a hobbled pen? Not unless they are brainless. Could an editor get rid of his brains any more effectually on a surgeon's table in a well-appointed hospital than he could by allowing an advertiser to club him into submission? Why go further in this vein?

How may a capable medium be known? How does a Mason know another Mason? You say he gives a sign! Does he not display his intelligence? Swapping editors for Masons for the moment, would an editor display any intelligence were he to go to a hospital and say to the surgeon: "Remove my brains from their present abiding place and put them in a glass jar for safekeeping; I do not need them just now; I get money for letting other people think for me."

How long do you imagine that these "thinkers" would support the industry? Let me tell you: just long enough to convince readers that the editor's brains are in a jar on a shelf in the hospital.

What is the sane conclusion? Let us reach it together: The readers of a paper that is edited by "jarred" brains, were they to go to the hospital to have an operation performed upon them, would fool the surgeon and the jar would remain empty. Such readers would have no purchasing power, hence they would be of absolutely no value to an advertiser.

If the advertiser can reap no reward by patronizing a paper, how is the subscriber to get his money's worth out of it? The cost of reading a worthless medium is more than the subscription price; the time consumed is worth something; but, more, the lost opportunity is not to be thrust aside—it might represent whatever it would cost to be decoyed into buying an automobile that it not fitted to the intended service.

But if a man purchases that which he cannot use, no matter what the cost of it might be, he still has to purchase what he wants, and the cost of it must be added to the money wasted; such are the ramifications; they, in a measure, indicate the responsibilities of the character of editor who prefers not to call upon the surgeon.

Doings in the East

PHILADELPHIA CLUB PREPARING FOR FALL RUN—AUTOCAR COMPANY ESTABLISHES SCHOOL FOR DRIVERS—PREPARATIONS COMPLETED FOR SYRACUSE RUN—TRADE ITEMS

—Edwin Swartley, Philadelphia manager for the KlineKar, has resigned.

—William F. Adams has been appointed manager of the Grout branch in Boston and Allie McKenna has been made assistant manager.

—The Moon car is again represented in Boston after a lapse of two years, this time by the Linscott Motor Company. It was taken on to fill out the line.

—F. Wallis Armstrong Company, of Philadelphia, announces that on September 1 the company assumed the assets and liabilities of Powers & Armstrong Company, of the Quaker City.

—President H. O. Smith, of the Premier Company has rewarded Henry L. Johnson, who has so successfully managed the Boston branch for the past few years, with an important factory position.

—The Fanning Motor Company, Philadelphia distributer of the Thomas Flyer, has secured new and more attractive quarters in the Scottish Rite building, southwest corner of Broad and Race streets.

—The Petrel car, a product of Milwaukee and a newcomer to the Philadelphia field, will be represented there by Reamer & Haines, 2214 Spring Garden street, which firm now handles the Baker Electric.

—Boston will have two additional motor chemical wagons if the new fire commissioner, Francis M. Carroll, has his way. He asks for them in his estimate just made up and puts the price at $11,000.

—Jay B. Cothran has been appointed manager of the New York branch of the Fisk Rubber Company to succeed E. H. Broadwell, who has been named vice-president and general manager of the Hudson Motor Car Company.

—The American Automobile Company, of Boston, has secured William P. Barnhart for its manager. He had been manager of one of the big taxicab companies for a couple of years and succeeded in correcting many abuses.

—The Amos-Pierce Automobile Company, of Syracuse, N. Y., will be succeeded in a few days by The Standard Automobile Company, of which C. Arthur Benjamin is the controlling spirit. C. L. Amos and H. C. Pierce have constituted The Amos-Pierce Automobile Company.

—F. G. Seitz, until recently assistant sales manager of the Olds Motor Works, of Lansing, Mich., has been appointed by that company as manager of its Philadelphia offices. His territory will embrace Eastern Pennsylvania, Southern New Jersey, Maryland, Delaware, Virginia and part of West Virginia.

—According to announcement of the S. B. R. Specialty Company, of East Orange, N. J., action has been commenced against the S. Toffler Company in the United States Circuit Court of New York praying for injunction and damages on account of alleged infringement of a muffler-cutout patented by the complainants.

—A 40-horsepower motor chemical has been installed at Belmost, Mass., having successfully passed the required test for efficiency. It will carry 10 men, but on the test more than a score were whisked along over a mile course in four minutes. Previously the machine went 300 feet and had a stream playing in 15 seconds.

—One of the latest additions to Philadelphia's automobile row is the Owen car, the agency of which has been secured by E. R. Jackson and W. H. Walter, under the firm name of the Jackson-Walter Company. The company is temporarily transacting business from the Bellevue-Stratford garage, pending the securing of suitable quarters on North Broad street.

—The Autocar Company, of Ardmore, Pa., has recently inaugurated an unique school for instructing drivers at its factory, where each purchaser of an Autocar truck may send his driver to secure a complete course in the knowledge of all vital parts of construction and the first rudiments of repairing, shifting of gears, application of brakes and general points on the care and use of the car. T. H. Dwight, an auto expert, delivers daily lectures on the cooling and oiling systems, etc. The object is to make assurance that the driver thoroughly understands his car and helps to protect the general public by eliminating the novice from the steering wheel of the commercial truck.

—Arrangements are being perfected for the Fall run of the Automobile Club of Philadelphia, which is scheduled to take place on Saturday and Sunday, September 17 and 18. The only definite thing known at present concerning the route is that of the distance—approximately 120 miles on each of the two days. The following have signified their intention of participating: Chalmers, Harvey Ringler, driver; Stevens-Duryea, Frank Hitchcock; Pierce-Racine, D. Walter Harper; Stoddard-Dayton, W. W. Randall; Stearns, Mrs. H. B. Ullman; Stanley, Mrs. D. Walter Harper; Buick, Mrs. Edward Wilkie; Jackson, Ira L. Brown; Cadillac, H. R. Shoch; Buick, Edward Wilkie; Buick, Thomas Wilkie; Marmon, Joseph Hudson; Owen, E. R. Jackson; Locomobile, Howard McTurk; Pullman, W. C. Longstreth; Premier, Alan Sheldon; Brush, Charles Kammerer; Interstate, M. Wertheimer; Palmer-Singer, Chas. Miller; Premier, H. E. Grant; Stevens-Duryea, F. W. Eveland; Mitchell, Walter Cran; Elmore, Frank Hardort, Sr.

—The date of the Syracuse *Herald* Sociability Run has been definitely fixed for Saturday, Sept. 24. It is the second annual run promoted by this paper. The route has been determined; Syracuse to Camillus, to Elbridge, to Auburn, Owasco, thence to west shore of Skaneateles Lake, Skaneateles Village, Marcellus, Camillus, Syracuse, in all 75 miles. The run is through a beautiful region, and the start will be made at 1:30 P. M. and the run will be finished about 5 o'clock. The secret time allowance will be placed in the hands of Mayor Edward Schoeneck. The winner will receive the *Herald* solid silver trophy, valued at $100. Like all the other prizes, this will be for permanent ownership. The Syracuse Automobile Dealers' Association will give the second prize, a silver cup valued at $50. The other prizes, all donated by the *Herald*, include gold medal to third and silver medal to fourth and gold and silver medals to the second and third women drivers coming closest to the secret time. The Automobile Club of Syracuse donates a silver cup to the woman coming closest to the figure establshed.

New Jersey Only State That Don't Reciprocate

ALBANY, Sept. 3—The Secretary of State announced last night that in conformity with the supplementary opinion rendered to him by Attorney-General O'Malley, the list of States now exempt from registering here under the Callan law is as follows: California, Connecticut, Delaware, Florida, Illinois, Indiana, Iowa, Kentucky, Maryland, Massachusetts, Michigan, Minnesota, Missouri, Maine, Nebraska, New Hampshire, North Carolina, Ohio, Oregon, Pennsylvania, Rhode Island, South Dakota, Utah, Vermont, Virginia, Washington and Wisconsin.

The Province of New Brunswick, Canada, is also exempted under the new law. The other Canadian provinces are not as they require auto tourists to register.

New Jersey is the only Eastern State now that does not have reciprocal relations with New York's automobile laws.

Overland Wins the U. S. M. Test

PHILADELPHIA, Sept. 3—The Overland car was victorious in the United States Mail automobile efficiency test which started last Monday and continued during the week under the joint direction of the Philadelphia Post Office officials and the Quaker City Motor Club. Each day the cars made the first delivery of mail to Bustleton and Torresdale, near-by suburban points. The primary object of the test was to demonstrate that the mail could be carried more rapidly and reliably, as well as more economically, by this modern method than by the old-time and antiquated system of horse and buggy delivery.

Incidentally, there was competition between the different makes of cars, for which a prize will be given. The complete returns of the run, from August 29 to September 3, inclusive, were announced to-day as follows:

Date	Car	Driver	P. O. Station	Mileage	Start	Fin.	St'ps	Time
8/29	Bergdoll	Vaughan	Torresdale	19 2-10	7.05	8.58	102	1.53.
	Maxwell	Smith	Bustleton	18 2-10	7.30	9.37	79	2.07*
8/30	Hudson	Yerger, F.	Torresdale	19 2-10	7.08	8.49	102	1.41
	Oakland	McGee	Bustleton	18 2-10	7.25	9.29	79	2.04
8/31	Overland	Greenwood	Torresdale	19 2-10	7.03	8.38	103	1.35†
	Kline Kar	Morton	Bustleton	18 2-10	7.40	9.15	79	1.35
9/1	Kline Kar	Morton	Torresdale	19 2-10	2.11	4.03	102	1.52
	Pullman	Bitner	Bustleton	18 2-10	7.30	9.10	79	1.40
9/2	Reo	Yerger, I.	Torresdale	19 2-10	7.13	4.40	102	9.27
	Parry	M'Cullough	Bustleton	Failed to report for run				
9/3	Mitchell	Bishop	Torresdale	19 2-10	7.16	8.54	102	1.38‡
	Haynes	LaRoche	Bustleton	18 2-10	7.48	9.26	79	1.38

(*) Five minutes off, blocked at railroad crossing.
(†) Two minutes off, extra stop in Bucks County, off route.
(‡) Four minutes off, extra stop in Bucks County, off route.
Overland wins. Time, 1.33.

Contest Board Awakened to Action

The glaring fault in the present plan of sanctioning meets was called to the attention of Chairman Butler of the Contest Board by THE AUTOMOBILE; it was admitted that the situation is a menace to clean sport, the following notice resulting:

> Attention is called to Rule 78 of the 1910 Contest Rules in regard to "Records," which provides that the Contest Board shall pass upon all records and may decline to accept any claim which, in its opinion, would not promote the interests of the sport; that no claim for a record of one mile or under and up to five miles will be considered by the Contest Board unless the same is taken by an automatic electrical or mechanical timing device approved by the Board; that no record will be recognized unless claim for same is made within ten days of its accomplishment, unless the Contest Board consider that the circumstances warrant a delay, and that no claim for record will be considered unless the sworn statements of the referee, chief timer and surveyor of the track or course are presented to the Contest Board.
>
> It should be clearly understood that no performances of one mile or under and up to five miles which are timed by stop watches only will be accepted by the Contest Board or recognized as breaking existing records for such distances.
>
> It is a well recognized fact that in the timing of cars at high speeds the personal equation of the individual watch-holder is too variable a one to permit of the results so obtained being made the basis of award of speed supremacy when the dividing line between existing and new records is narrowed down to a few fifths of a second.
>
> The considerable publicity which has recently been given certain track speed performances timed by stop watches in the hands of individual timers is wholly without official recognition or acceptance.

Silent Knight Patents Gone to Issue

Some of the controversies in relation to the basic character of the Knight patent may now be extended without the reader being wrongly informed. While the general design of the Knight motor as it is used in the British Daimler and certain other foreign cars is quite well understood, the fact remains that the patent has been held as a secret up to a day or two ago.

Middle West News

COLUMBUS LEGISLATING AGAINST OPEN MUFFLERS—OHIO'S ATTORNEY-GENERAL HOLDS THAT JUSTICES OF THE PEACE HAVEN'T FINAL JURISDICTION IN AUTOMOBILE CASES—NEWS OF ALL SORTS

—Frank B. Willis, of the Willis-Holcomb Co., will succeed Frank Staley as manager of the Studebaker Brothers Company of Indianapolis.

—At Washington C. H., Ohio, enterprising citizens have subscribed $50,000 of $75,000 necessary to secure the Pilot Automobile Company for that place.

—The Adams Bros. Company, of Findlay, Ohio, has been formed to build commercial trucks, and a large plant at that place has been leased by the concern. L. A. Adams is president of the company.

—The Columbus Buggy Company, of Columbus, Ohio, has completed its models for gasoline cars for 1911. The company announces eight models, which will include the full line of touring cars, runabouts and landaulets.

—The McLeary Engineering Company, of Toledo, has been incorporated with an authorized capital of $25,000 to manufacture and sell motors for aeroplanes and automobiles and to do a general automobile repairing business.

—Creditors of the Indiana Motor and Manufacturing Company, which makes the Continental "35," have decided that the plant shall remain in operation. The company has its principal offices in Indianapolis and its factory at Franklin.

—The automobile manufacturers of Indianapolis have agreed to test their cars on the Motor Speedway, instead of in the streets and on country roads. At the Speedway a man will be assigned to keep a record of the work of each test car driver.

—Announcement has been made that the recently organized Auto Sales Company, of Indianapolis, has taken over the business of the Auto Motor Company at 23 Kentucky avenue and with it the Fuller, Cutting, Monitor, Jackson, Westcott and Demot agencies.

—The Hudson Sales Company, of Columbus, Ohio, of which Levi R. Smith is manager, has been organized to take the 1911 agency for the Hudson in Central Ohio. The concern has located at 241 North Fourth street, and consists of a partnership of Levi R. Smith and William Gaither.

—The Great Western Automobile Company has announced that it will guarantee its 1911 "40" model against defects for one year from the time of purchase, and has authorized its agents and dealers to sell with that provision.

—An ordinance was introduced in the Columbus, Ohio, City Council by Councilman Ernest M. Baldridge providing that every automobile, motor-cycle or other self-propelled vehicle, excepting automobiles operated by electricity, must be provided with a muffler when operated on the streets of the city in order to make less noise.

—A number of improvements are to be made at the Indianapolis plant of the Premier Motor Manufacturing Co., which has bought considerable property in Georgia street, opposite its present plant. An immense machine shop and several other buildings are to be erected immediately, the contracts for these having been let.

—In an opinion recently handed down by Attorney-General U. G. Denman, of Ohio, to William Brown, Cleveland justice of the peace, it is held that a justice of the peace has not final jurisdiction in a prosecution for violation of the State automobile law unless the accused either pleads guilty or waives the right to trial by jury.

—The Case Motor Car Company, capital $50,000, has been incorporated at New Bremen, Ohio, by J. H. and Edmund Grothaus, J. F. Laufersieck, Otto J. Doesel, Louis Huenke and others. The former plant of the Grothaus-Laufersieck Company will be fitted up for the manufacture of commercial motor trucks.

The Week in Detroit

ORGANIZERS AT WORK UNIONIZING THE AUTOMOBILE FACTORY HANDS—NEW CARS ON THE MARKET—NEW FACTORY AND AGENCY BUILDINGS—TRADE AND PERSONAL NOTES

DETROIT, Sept. 5—Automobile interests are viewing with mixed emotions the operations of six international union organizers who have been working among the various branches of skilled labor in the factories here. While other lines are involved, the automobile industry has been given the most serious consideration by these organizers, who express themselves as gratified at the progress made. For years trades unionism flourished here. Then it fell into decadence, workingmen preferring to go it alone. Then the building trades council was wrecked while fighting the employers, and since that time the open shop has prevailed in most quarters, a man's affiliations with labor bodies not being taken into consideration by employers. The automobile industry has furnished employment to thousands of skilled mechanics. Not less than 50,000 men gain a livelihood from the motor car and allied interests in this city. They receive the highest wages and are content. It is due in no small degree to this happy state of affairs that the industry has grown to such proportions. Whether these conditions are to be disturbed and whether the advent of labor organizers will inject a discordant element, is what is causing employers and the great majority of the workmen themselves to watch developments with more than passing interest. The men working here are Thomas H. Flynn, general organizer for the Federation of Labor; Clarence Dowd, Amalgamated Association of Machinists; L. D. Redding, Amalgamated Association of Meat Cutters and Butcher Workmen; Martin Ludwig, International Metal Polishers; John J. Hynes, Sheet Metal Workers; Harry T. Ajax, Journeymen Tailors.

John N. Anhut, former president of the Anhut Motor Car Co., whose absence from the city at a time when the affairs of the company were in a chaotic condition caused some little gossip until he was finally located in Europe, returned home last week and has been busy with his campaign for renomination for State Senator ever since.

The Faulkner-Blanchard Motor Car Co. has been organized to manufacture the Faulkner-Blanchard "Gunboat Six," designed by Frederick W. Blanchard. M. A. Faulkner is president and manager of the company, which has not as yet decided upon a location.

Detroit's automobile fire engine, which has been in active service for some time, demonstrated its value one day last week when it made a run to Grosse Pointe, a fashionable suburb, in response to a call for help. The distance traversed on the outbound trip was 10 1-4 miles, this being covered in exactly 19 minutes, including one full stop and several slowdowns, demonstrating the value of the engine in the event of reinforcements being required in distant parts of the city.

The E-M-F Company has purchased two acres of additional ground adjoining its plant on Clark avenue, which will enable it to double the size of buildings it will shortly erect at this point.

The big Buick factory in Flint has resumed operations on a conservative basis, and, with several new car and parts factories nearing completion, plans are under way for still further extensions before snow flies.

The Bower Roller Bearing Co., makers of roller bearings for automobiles, railroad cars and all kinds of rolling stock, now located in Dayton, O., will begin work immediately on a large new factory at Goethe avenue and Hart street, plans for which have been prepared by Architect Albert Kahn and Ernest Wilby, associate.

A group of buildings that will double its present capacity is being erected by the Kelsey Wheel Co., 1208-1250 Military avenue. The plant, when the additions now going up are completed, will represent an investment of $200,000, and still further improvements, to cost not less than $100,000, are contemplated.

A building permit has been taken out by the Packard Motor Car Co. for a $10,000 power house, to be used in connection with its foundry and forge shops. The company is also putting in loading tracks at its No. 8 plant, on Bellevue avenue.

The "Suburban Limited," which will be manufactured here by the DeSchaum Motor Car Co., made its appearance on the streets last week and attracted considerable attention. It is a light car, of from 16 to 20 horsepower. All parts are Hecla steel and practically all of them are under the hood. It will sell from $900 to $1,000. The company is composed of 10 Detroit business men, including W. Andrew DeSchaum, designer of the car. They expect to turn out 500 cars next year.

The dedication of the completed portion of the immense new plant the Warren Motor Car Co. is building on Holden avenue, last Thursday night, was a most enjoyable affair. Two orchestras furnished music for dancing, which was participated in by some 300 couples, including employees and their ladies. Postmaster Homer Warren, president of the company, gave a brief talk, in which he thanked the employees for their hearty co-operation.

American Cars for 1911

(*Continued from page* 416.)

pair of gears in mesh at one time, and the means of locking are not only positive, but of such a rugged nature as to assure this positive action for all time.

Passing beyond the question of universal joints at the several necessary points, they being well represented, it is pointed out that the brakes, of which there are two sets, located in large drums in the rear wheels arranged alongside of each other, internally expanding, have large surfaces and a means for expanding the shoes and are such as to give the maximum braking effect. The drums are protected by plates to keep out foreign matter and each pair of brake shoes in each drum is assembled as a unit.

This unit assembling idea obtains throughout the car. The live rear axle with its brake drums, including the torsion tube up to the universal joint, constitute a complete unit; the transmission gear represents a unit; the clutch and its mechanism another unit; the motor and its accessories form a unit, and so on. This unit system is again handled in the form of sub-units so that a proper description of the plant would include the idea that there are units within units.

Forty-inch wheels continue to be features of the Roadster, the Roadster Coupé, the Traveler, the Traveler Special and the Traveler Coupé, the remaining types being equipped with 36-inch wheels. The large wheel tire equipment is uniformly 40x4 front and rear, the cars fitted with the smaller wheels being shod with 36x4 tires on the front pair and 36x5 on the rear. The American standard equipment on the Roadster, Roadster Special, Traveler, Traveler Special and Tourist includes: Top and slip cover, shock absorbers on rear, Continental demountable rims (two spare), Prest-O-Lite tank, spare tire irons, full lamp equipment, horn, tool kit and jack.

There will be a slight change in prices of American cars for 1911. The Limousine, $5,250; Tourist, $4,250; Roadster, $4,250, and Traveler, $4,250, will cost a trifle more than last year, the prices of the Roadster Special, $5,000, and the Traveler Special, $5,000, remaining unchanged. The Roadster Coupé is listed at $5,250; Traveler Coupé, $5,250, and the new Speedster at $5,000.

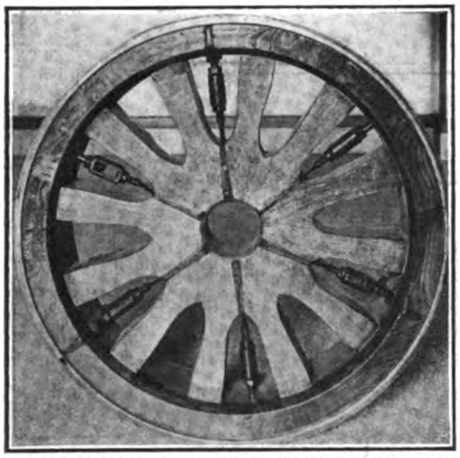
Prominent Automobile Accessories

THE ADJUSTABLE WEDGE WHEEL



New Turner patent wheel for heavy duty; by means of adjustable wedges it is possible to tighten up the wheel on the road

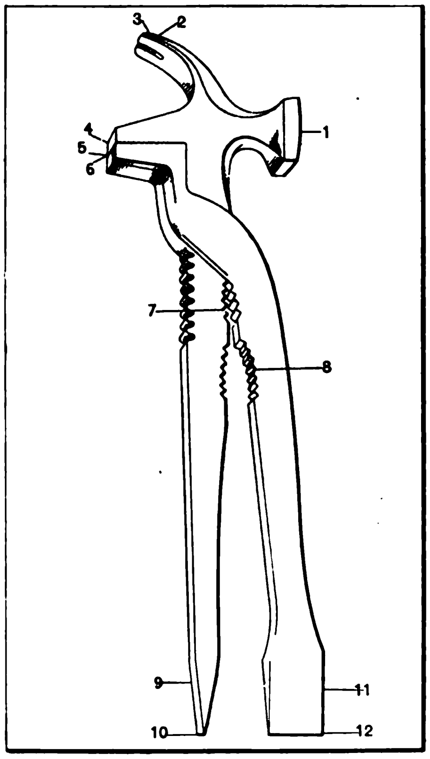
The new Turner adjustable wedge wheel, an English invention, which may now be seen running on General and Vanguard omnibuses in London, is about to be introduced in this country by Chas. G. Norris, who for the present is to be found at the Engineers' Club, New York. The "staff" photographer of THE AUTOMOBILE photographed one of the new Turner wheels and an illustration of it is given here. Mr. Norris states, in relation to the qualities of this wheel, that "the main idea of this invention was to do away with the unpleasant creaking noise by producing a wheel in which the structural elements could be tightened up from time to time without removing the wheel from its axle, and obviously saving the expense of sending same to the wheelmaker to deal with, which operation is expensive, as under present methods of dealing with a creaking wheel all gearing and tires have to be removed before efficient repairs can be made, to say nothing of loss in running and carriage expenses."

Shocks are spread over the entire wheel, instead of two or three spokes having to take the strains; in this wheel the structural elements are in compression and tension. Further, the soles of the felloes are not burnt and charred, as is the case when steel bands are put on hot. These burnt and charred portions in a wheel, it will be easily understood, are the primary cause of wheels becoming creaky and loose, viz., by the charred portions, together with scales formed on inside of rims, working into powder and escaping from under the rims, thus leaving space for the wheel to start working loose. Of course another great cause of wheels getting loose is the introduction of unseasoned timber, which when exposed to dry weather shrinks up and leaves spaces. When this happens with the present type of wheel there is nothing left to do but rebuild the wheel again. But with the new system of interposing a series of wedges between the wood elements of the wheel it is possible to take up all space so created by simply using a spanner to turn the nuts and couplings, which may be done in a garage, or even on the road by the drivers.

There is no limit to the tightness attainable in this wheel, as is the case when contracting the rims on hot, when 7-8 inch contraction is the most that is obtainable by this method; and, taking into consideration that generally about 3-8 inch on the sole is burnt away and 1-4 inch joint at least should be left to draw up, there is really only 1-4 inch effective tightness in the wheel, to say nothing of the rim being made unserviceable after two or three times of so contracting the same.

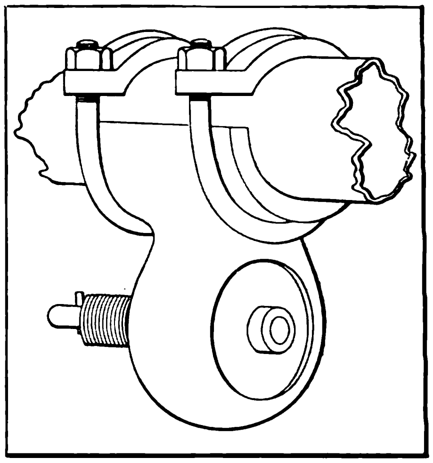
A TOOL OF MANY USES

Combination tools, if the autoist is not to clutter up his tool-box with a multiplicity of implements, are highly desirable. In this connection the "Rex," made by the Perfection Tool and Accessory Company, 1777 Broadway, New York City, is the acme of compactness in the varied uses to which a single implement may be put. The illustration shows no less than a dozen different ways in which this handy tool may be used.



New combination tool—can be used as: 1—Hammer; 2—tack puller; 3—valve lifter; 4—riveting mallet; 5—wire-puller; 6—monkey wrench; 7—1-2" pipe wrench; 8—1" pipe wrench; 9—tire iron; 10—screwdriver; 11—tire iron; 12—chisel

EASILY APPLIED MUFFLER CUT-OUT



A new muffler cut-out which may be easily applied; it is also a carbon-catcher

In the accompanying illustration is shown the muffler cut-out now being marketed by the S B R Specialty Company, of East Orange, N. J. In applying it all that is necessary is to saw a small piece from the underside of the exhaust pipe and clamp it into position. Once applied it acts not only as a cut-out, but also as a carbon catcher, for it contains a pocket into which most of the residue from the engine falls, this being forced out by the exhaust when the cut-out is opened. To prevent leakage the valve is made to open against the exhaust pipe's pressure.

SINGLE-TUBE FOUR-TONE HORN

A new model of Gabriel Horn, made by the company of the same name at its Cleveland, O., factory, was recently placed on the market. It is styled the No. 4 Four-Toned Horn, and although having but one tube it gives four distinct mellow notes. It is 3 x 32 inches in dimensions, making it very convenient to attach to any style of car. The stock finish is highly polished brass, but on special order the horn will be furnished with oxidized, black lacquer or nickel-plate finish.

TO KEEP THE CAR LOOKING NEW

The owner of a high-priced car can lose the prestige which goes with its ownership by allowing it to become dingy and dirty in appearance. An excellent aid to a continued glossy and new appearance of the body, metal and leather parts is Auto Renew Gloss, manufactured by the Superior Specialty Company, 418 South Third Street, Louisville, Ky. This preparation cleans and polishes at the same time, preserving woodwork, tops and cushions from becoming dry and cracked and acting as a surface-food to the finishing coat. It dries instantly.

Vol. XXIII New York—Thursday, September 15, 1910—Chicago No. 11

THE AUTOMOBILE

1911 Laboratory Prospects

PURCHASING PUBLIC INTERESTED IN LABORATORY WORK; A. C. A. PERFECTS ITS LABORATORY; MANY MAKERS INSTALLING TESTING EQUIPMENT

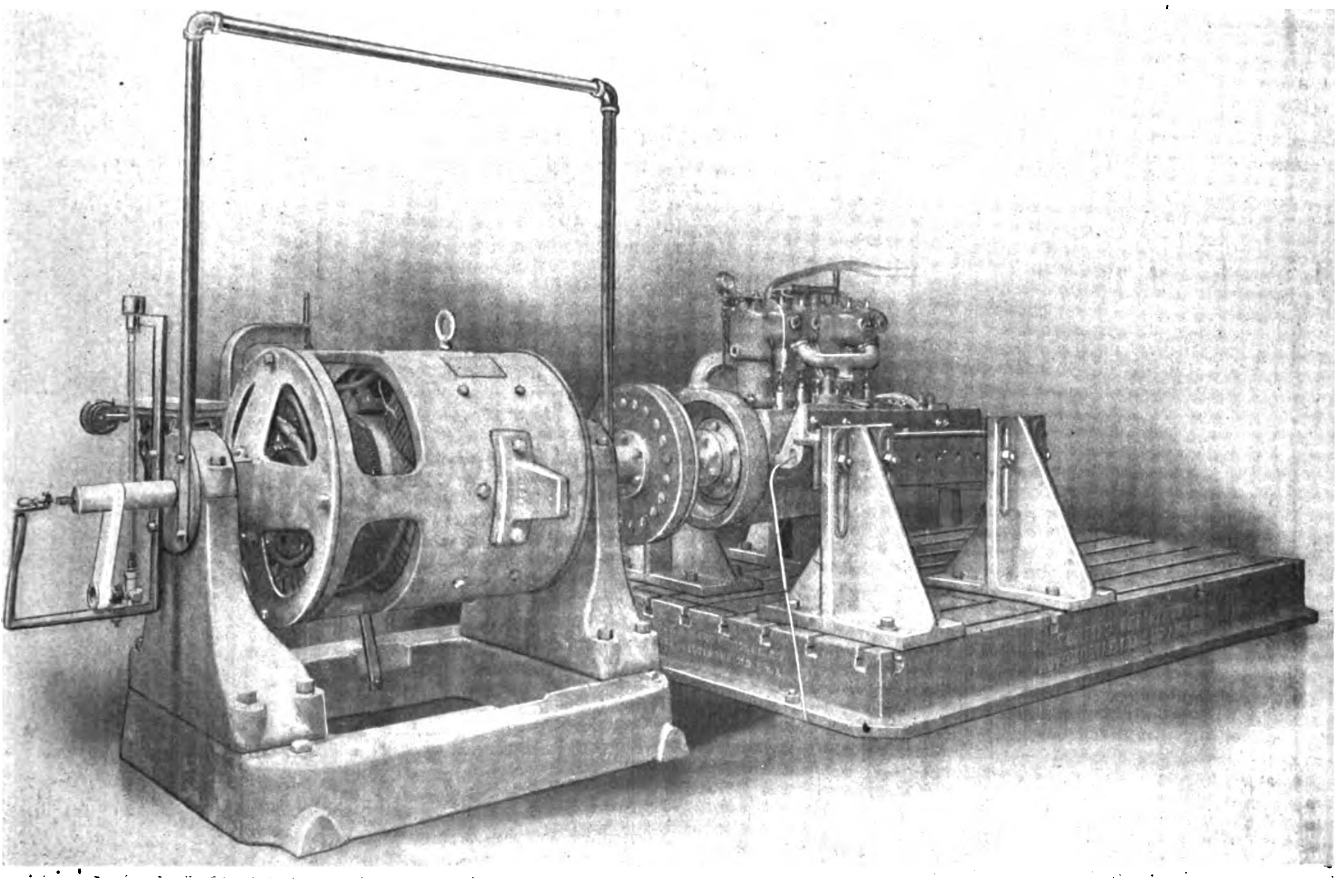


FIG. 1—MOTOR MOUNTED FOR DYNAMOMETER TEST IN APPARATUS INSTALLED BY AUTOMOBILE CLUB OF AMERICA

CONTRARY to accepted belief in the haunts of the average man, natural laws are fixed, unalterably so, and fortunately they are beyond the pale of the influence of the character of man who labors under the impression that the result of his handiwork is the absolute standard. The real situation is quite different from that of popular belief. When an apparatus is designed and constructed, it then remains for the designer to find out how many natural laws the equipment violates, and to what extent the design offends these laws. The laboratory problem may be divided into three fundamental classifications, *i.e.,* (a) for the investigation of the raw materials that are proposed for use in the construction of machines, as automobiles, (b) for the purpose of determining the extent of compliance of component units with the laws. (c) in the conduct of final tests of the completed automobiles leading up to a better understanding of the harmony of relations of the component units. These are all matters with which manufacturers are primarily concerned, but it still remains to determine as to the fitness of the completed automobiles from the point of view of road performance and in the light of the intended service. This latter consideration is a paramount issue with the purchaser, and on this account users of automobiles, as they are banded together in clubs, combine their individual efforts as a unit with the expectation that the cost of a (common) user's laboratory will not be too much of a burden to carry, but that it will be the source of much light on a relatively dark subject, and beneficial (a) to the user since it will tell him if the automobile he may select is in accord with the promises made for it by the maker, (b) to the maker in a measure depending upon his willingness to listen to the voice of experience.

It would be a great misfortune were the makers of automobiles, taking them broadly, to find themselves in the predicament which would be in evidence were they to be laggards in the matter of the installation of suitable laboratory equipment, and find themselves in the position of having to listen to disgruntled users. This unfortunate situation is likely to be brought about if clubs install capable laboratory equipment and put it under the charge of skilled physicists, provided the makers build their cars by rule of thumb at the command of coarse practice, rather than in the enlightened atmosphere of the laboratory, at the instance of men who learn what the natural laws portray and bow to the inevitable.

Fortunately, the wheels of progress are not all being turned by the users of automobiles; the clubs, made up of enthusiastic autoists, that spend a part of their surplus by way of the laboratory, in hunting out the bottom facts about the automobiles they ride in, are most likely to discover, when their excellent undertakings are concluded, that they are treading a path that was blazed by the makers' engineers in works laboratories.

The growth of the automobile industry owes much of the rapidity of its expansion to the interest that is displayed in the automobile by the men who have to pay the bill. When the owners of cars elect to spend hundreds of thousands of dollars in laboratory research, it goes to show that they will recognize merit for what it is worth. In other words, the time is rapidly approaching when these owners will know a good automobile when they see it, and what is more to the point, they will know just why it is good.

On account of the rapid strides that are being made and the fact that laboratory equipment is being installed in the shops that were not heretofore equipped in this way, and in the automobile clubs of importance, it would seem to be a good subject to enlarge upon at some length, perhaps, the idea being to advise the makers of cars of the preparation that is being undertaken by users to enable them to find out where they stand, with the further understanding that users of automobiles, since they appreciate the utility that resides in a well-equipped laboratory, be put in possession of the latest facts as they refer to laboratory practice.

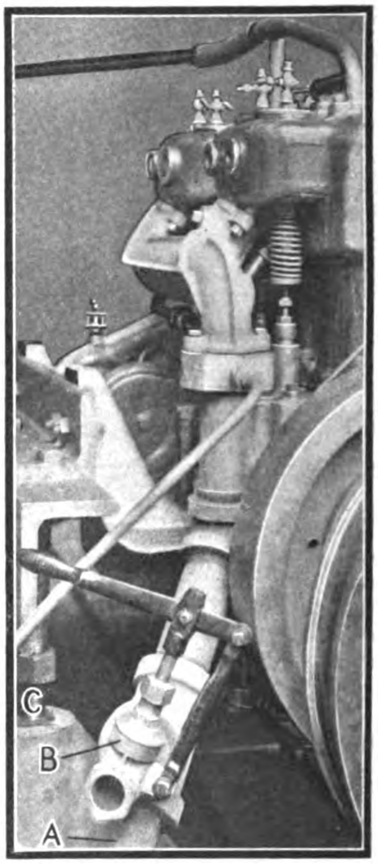

Fig. 3—Exhaust pipe A leading to flue with branch attachment B for taking samples of the exhaust gases. To the left one of the jackscrews C of the supports for adjusting the height of angle irons

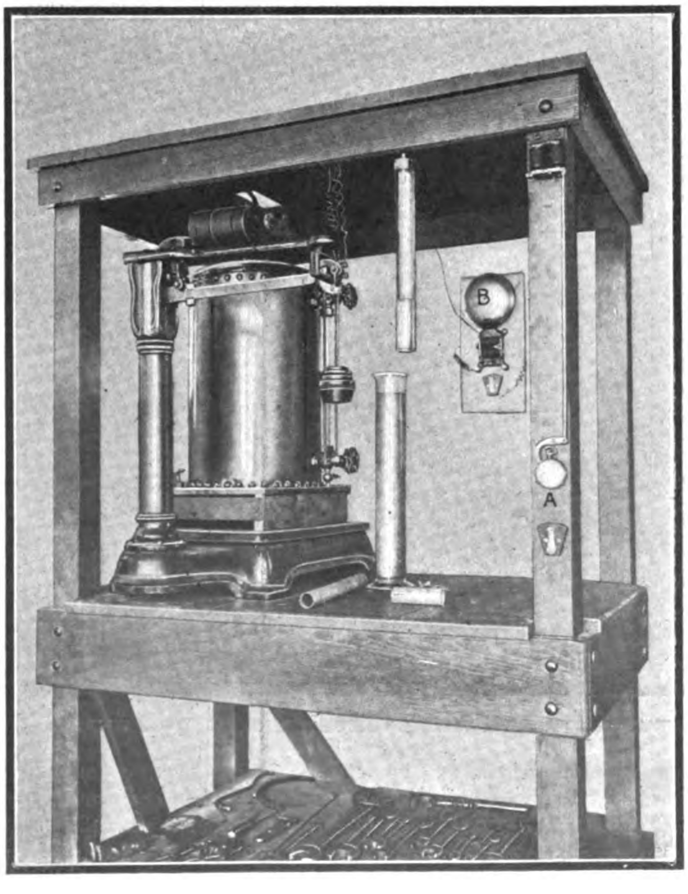

Fig. 2—Gasoline dispensing apparatus and scales with electrically operated stop watch attachment A, and bell B; feed pipe to carbureter not shown

A new apparatus has been installed in the testing laboratory of the Automobile Club of America under the direction of A. L. McMurtry, chairman of the Technical Committee, by means of which it is possible to obtain accurate determinations of the power of any motor submitted for examination, of its fuel consumption, with one carbureter or with another, and of the friction losses in a transmission operated at one gear or another. The torque may be measured at any number of revolutions between 500 and 2,000, and the fuel consumption at any adjustment of the carbureter which produces any given number of revolutions with a certain load, and, so far as fuel consumption is concerned, the speed of the motor may be below 500 without interfering with the accuracy of the measurement. The present arrangements provide for coupling the armature shaft of a Diehl dynamo with the flywheel of the motor by means of a coupling plate and suitable joints, and is applicable to a large number of motor flywheel equipments without change. In the case of motors provided with fan-spoked flywheels or with multiple-disc clutch, or when connection should be made with the shaft of the transmission gear, these arrangements may have to be modified somewhat in each instance.

If it is desired to measure the power of an automobile at the rims of the rear wheels, including all the variations which may be due to tire qualities, different degrees of inflation of the tires, slippage, and some other factors, which are usually of less interest to the owners or makers of automobiles than the efficiency of motor and transmission mechanism, the club's old and more complicated testing apparatus may still be used, and the difference in the results obtained by the new apparatus measuring the efficiency of the motor or the motor with the transmission alone, on one side, and, on the other side, those obtained by the old apparatus measuring the driving power of the same motor and transmission, after this power has undergone the reductions due to the factors referred to, may sometimes be of interest, mainly as a means for determining the value of those latter factors under different circumstances.

The main elements in the new testing apparatus are: The bed plate in which the supports for the motor to be tested are adjustably secured; the adjustable supports; the coupling, or means for connecting the motor shaft with the armature shaft; the dynamometer; the spring scale for sight readings of the torque.

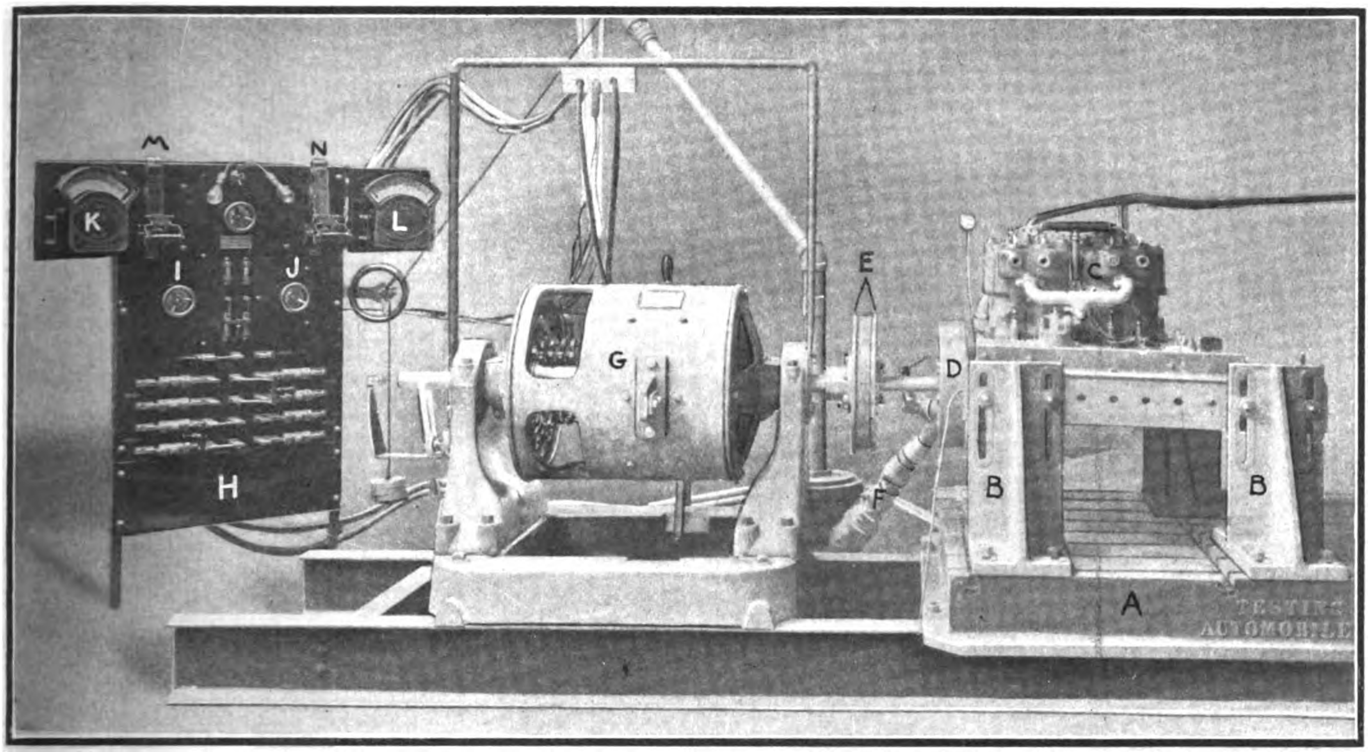

Fig. 4—Testing apparatus showing motor mounted for testing, the coupling device, the dynamometer and the switchboard. A, bedplate; B, supports; C, motor; D, flywheel; E, studded plates driving connection; F, exhaust pipe; G, dynamometer with wiring to switchboard; H, switchboard with rheostats I and J, voltmeter K, ammeter L and interrupters M and N

the Fairbanks scale for determining the same factor with precision within one-tenth of one pound; the Warner tachometer for sight readings of the motor speed; a Veeder counter with a trigger device for positively counting the number of revolutions for a given time; switchboard for regulating resistance to operation of the dynamo and incidentally permitting experimenting with the carbureter and throttle; a tank with water and soda in which the current produced by the motor under test is taken from the switchboard and dissipated in the work of separating the water into its constituents; a gasoline weighing and dispensing apparatus with stop-watch attachment permitting to ascertain the exact weight of gasoline which flows to the carbureter in a given time, such as one minute or twenty minutes, the latter being a standard period for one test.

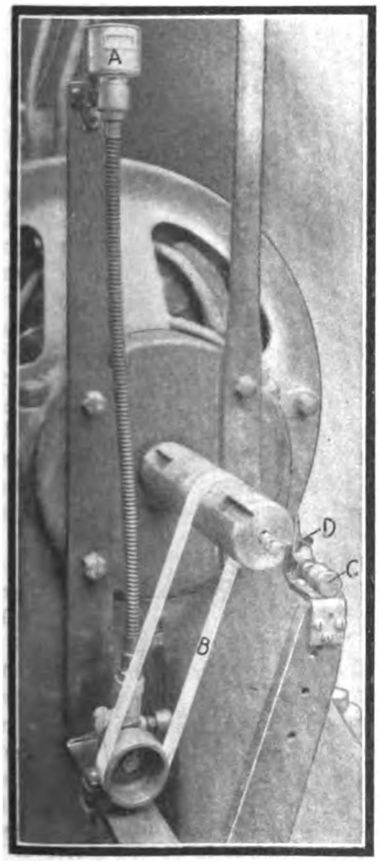

Fig. 5—Free end of armature shaft with tachometer A operated by belt B and counter C connected with or disconnected from shaft by trigger D

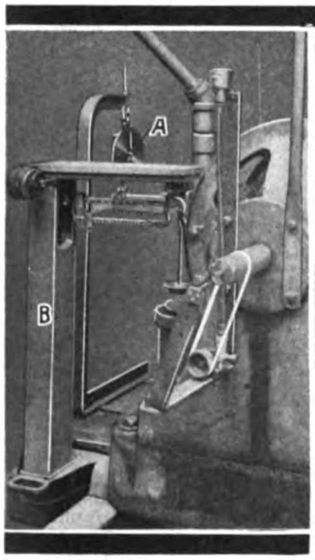
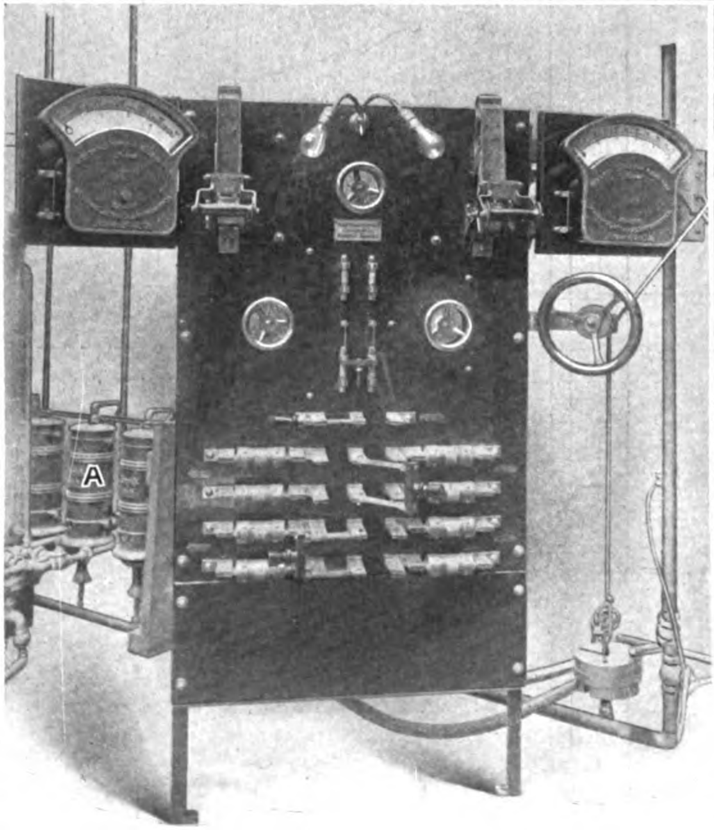
Suitable printed blanks for registering the various measurements and the exact conditions under which they are taken also form a part of the equipment, and a sharp distinction is made between blanks provided for non-certified tests which may be carried on by the owner of a motor, a carbureter or a transmission mechanism with the assistance of the laboratory engineer, but which may not be published or in any manner used for trade purposes, and, on the other hand, the fully certified tests in which all steps are taken under the direct and constant supervision of the laboratory directors.

The bed plate is a very substantial cast-iron structure on a wooden foundation and measures about six and one-half feet in length by five feet in width, as estimated by the eye, affording room for even very large motor plants. The upper portion of this bed is crossed lengthwise with nine T-grooves and crosswise with three, the T-portion being downward so as to afford room for the heads of the bolts by which the supports are secured, while permitting the bolts to be slid from one position in the grooves to another, according to the place where the supports should be fixed, first in order to fit with the crankcase brackets of the motor, and, in the final adjustment, to produce perfect alignment of the shafts. The dimensions of all the parts, including the bolts and nuts, are designed with a view to obviating or absorbing vibration. Adjustment of the supports is facilitated by having the bolts work in slots in the supports as well as in the bed plate. An angle iron plate connects the pair of supports on each side of the motor and may be secured higher at one end than at the other, for the case that the crankshaft has a downward tilt and is not parallel with the resting faces of the brackets. To the angle-iron plate with flat top may be bolted another angle iron, as in the illustrations, for the more substantial mounting of motors designed to be mounted in this manner in an automobile frame or subframe. The height adjustment is facilitated by jackscrews in each support, the screws impinging against the lower angle iron, and the adjustment being secured by bolts working in vertical slots in the supports, as plainly shown in the illustrations. By the means described it is possible to bring the center of the motor shaft in exact continuation of the armature shaft, provided there has first been secured to the face of the flywheel a true, concentric flange plate, fitting over the coupling plate which is part of the device employed for uniting the motor with the dynamometer shaft. The driving connection between these two elements consists in two studded plates fitting together so as to stagger the studs of the driving plate in relation to the studs of the driven plate and winding a leather belt or a rope in and out, and over and under the studs. To this well-known, slightly flexible form of coupling there has been added a circumferential leather strip, as shown in the illustrations, which, however, plays no part in the coupling, but may serve to prevent the clothes of operators from being entangled with the revolving plates. The end of the armature shaft is provided with a cylindrical sleeve surrounding the joint connecting with the coupling, and the latter is provided with a cylindrical flange fitting loosely to the said sleeve, so that the height of the two axes will remain the same while adjustments are made and after. It is stated that no appreciable heat is generated in any part of this coupling arrangement, and that consequently there is no loss of work there.





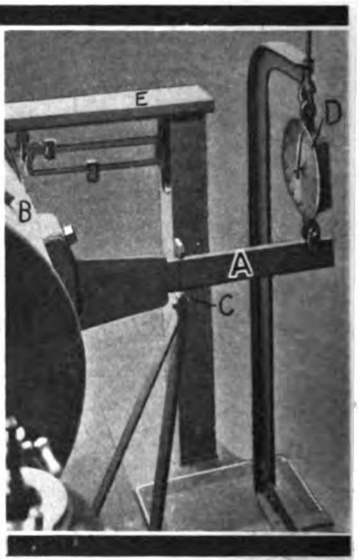


Fig. 6—Showing spring scale A mounted on Fairbanks scales B
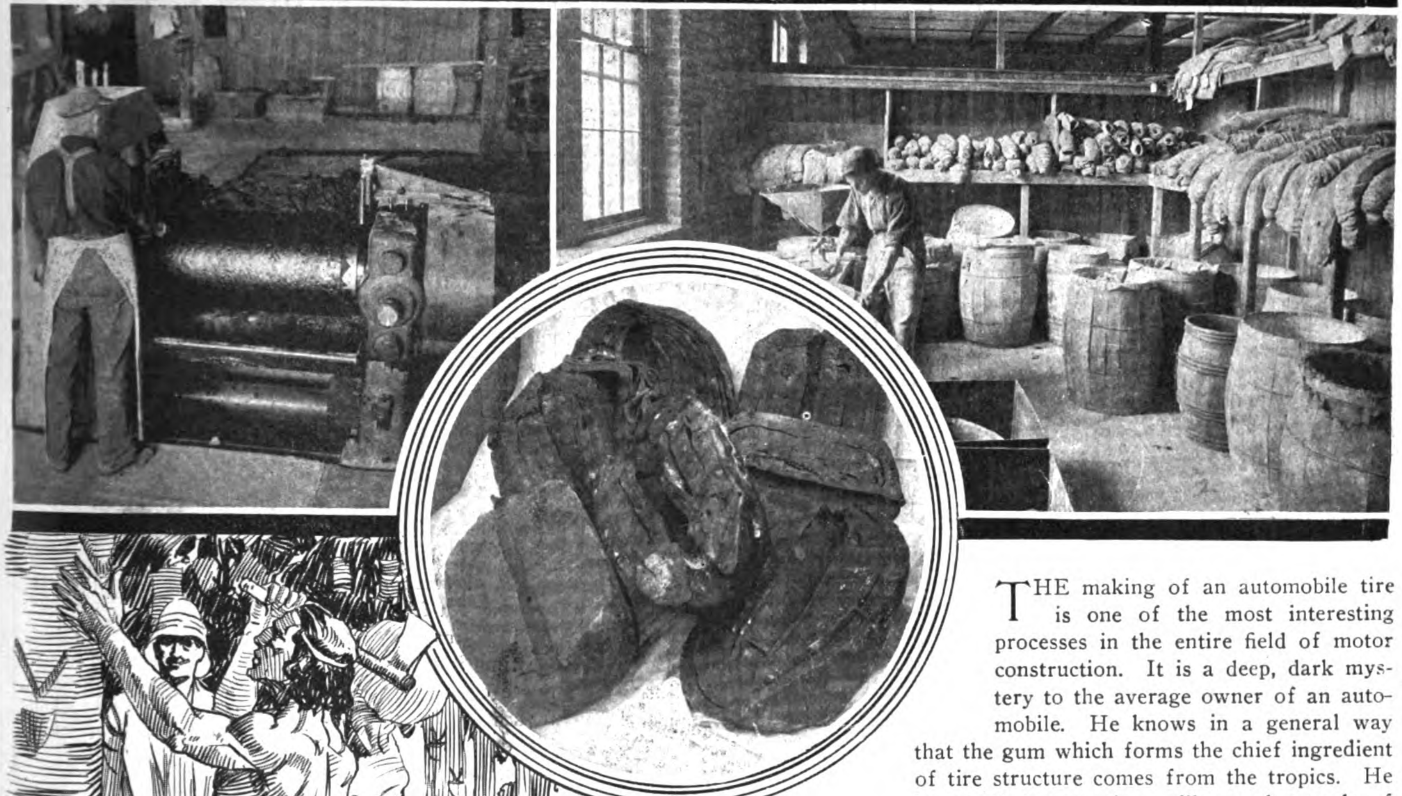
Fig. 7—Switchboard with water heating apparatus A
Fig. 8—Showing adjustable arm A of the dynamometer field housing B with stop C and spring scale D mounted on Fairbanks scale E

The dynamo is a Diehl, type 10, rated at 230 volts and 196 amperes, and consequently capable of handling slightly more than 45 kilowatts or about 60 horsepower. Its efficiency is guaranteed to remain constant between 500 and 2,000 revolutions. The free end of the armature shaft projects about one foot, and at this end are connected the Warner tachometer which permits a close estimate of the speed at a glance, and the Veeder counter which is operated only when a trigger is pulled establishing the connection with the shaft. By operating the trigger at the same time as the gasoline meter records a certain weight in the gasoline tank and disconnecting the counter after a certain elapsed time, when the meter again records the weight, the fuel consumption may thus be ascertained for a given number of revolutions and may be compared with the power rating recorded at the scales under the same conditions.

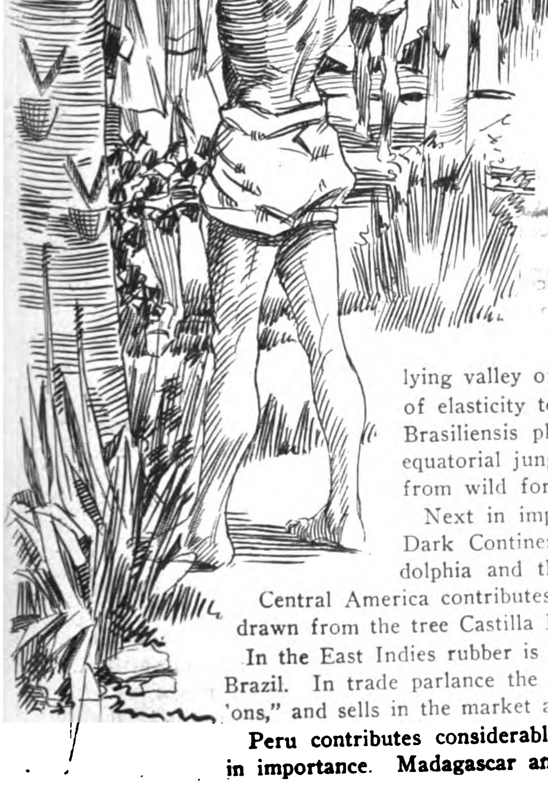
The housing of the dynamo field is provided with two diametrically opposite arms, one of which at a certain adjustable distance from the axis of the dynamo is attached to the operating rod of the spring scales, depressing it and producing a scale reading which may be observed in its variations from time to time, if such variations occur. The motion of the field and of the two arms is limited by an upper and lower stop, but within these limits the power of the rotation corresponds, of course, to the torque developed, and the scale-reading in conjunction with the radius at which it is produced and the known efficiency of the dynamo enable the operator to determine at a glance the horsepower developed. For greater accuracy the spring scales are mounted upon a Fairbanks scale, and the spring scale pull may, therefore, at any time of the test be balanced to within one-tenth of a pound. It is this latter reading which is used exclusively for deciding the power in certified tests, and it may furthermore be checked by the readings in amperes and volts at the switchboard, or more directly in kilowatts. The switchboard is equipped with the meters giving these measurements, and has obviously large switch contacts, being made by Diehl especially for use in connection with the dynamo and with a view to great variations in the power developed. It has two rheostats, one quite coarse in its adjustments for ready approximation of the resistance required for producing any desired motor speed with a given torque or vice versa, and another with very fine adjustments corresponding in nicety almost with the one-tenth pound accuracy of the Fairbanks scales. In practice, the usual way of operating is to use the rough rheostat for getting approximate motor speeds and powers and to check carbureter adjustments by means of the finer one. Under the present arrangements the current produced is taken away by an electric motor connected with the power shafts used in the garage work of the club, but it is the intention to take it instead, to a tank with water to which is added washing soda and to let the energy be expended in a chemical reaction, and it is stated by the laboratory engineer, Mr. Reilly, formerly of the Massachusetts Institute of Technology of Boston, that soda is preferable to salt which has been used for the same purpose, as the fumes are harmless, while chlorine fumes resulting from the use of salt as an admixture are obnoxious.

One of the illustrations shows the arrangement of the gasoline dispensing meter, with thermometer and the usual appliances for measuring the specific gravity of the fuel. When the scale on which the gasoline tank is placed has been balanced and a reading taken of the total weight of the tank and its contents for the beginning of a test, it is possible to work the apparatus so that the stop watch will indicate the periods after each of which the automatic scales shall indicate the loss in weight, the actuating means being the electrical connection which also rings the bell at the end of each predetermined period. But it is simpler in practice to have the automatic scales indicate the withdrawal from the tank, and consumption in the motor, of a given quantity of the fuel while at the same time causing the electric connection to operate the stop watch, so as to indicate time elapsed in the consumption of a given weight of gasoline

A Day with the Tire Makers



Left—First process in washing. Center—Pure Para rubber. Right—Store and cutting room



THE making of an automobile tire is one of the most interesting processes in the entire field of motor construction. It is a deep, dark mystery to the average owner of an automobile. He knows in a general way that the gum which forms the chief ingredient of tire structure comes from the tropics. He knows that some tires will run thousands of miles without giving their owner any trouble whatever and that precisely similar tires will vex the spirit, tax the resourcefulness and test the amiability of the owner by their likelihood to blow out or puncture at inconvenient moments.

Only a few years ago the structural strength of automobile tires was so uncertain as to form the principal element of chance in touring. To-day, like everything else in the line of development in motordom, the tires are stronger, more dependable, more uniform and more is expected of them than ever before.

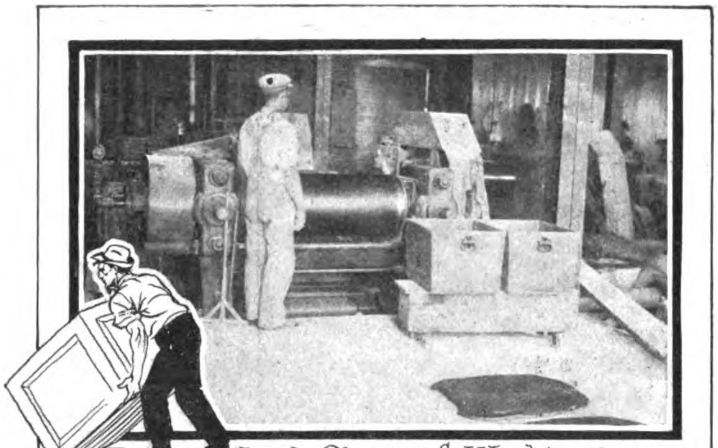
The rubber from which tires are manufactured comes chiefly from the Para district of Brazil, which includes a considerable portion of the low-lying valley of the River Amazon. The Para rubber is said to possess the elemental quality of elasticity to a greater extent than any of the other varieties. Two species of the Hevea Brasiliensis plant are the sources of supply in the Para country. The trees flourish in the equatorial jungles of the Amazon and at this time crude rubber from Para is practically all from wild forest trees.

Next in importance as far as bulk of supply is concerned is the African field. In the Dark Continent there are two distinct varieties of crude rubber supply: the vine called Landolphia and the tree, Kickxia Africana, which flourishes in West Africa.

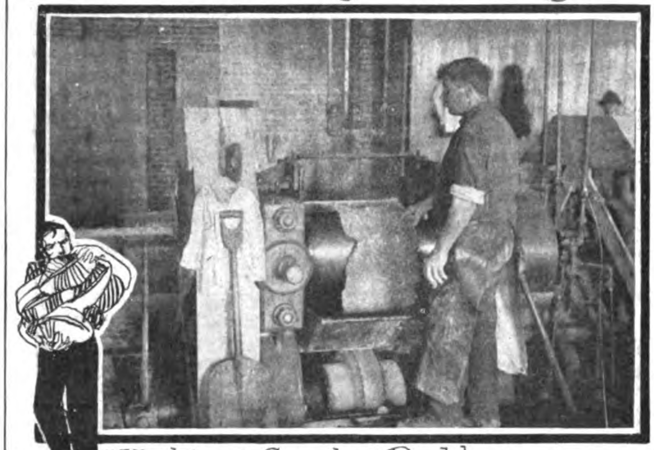
Central America contributes a large quantity of rubber, called "Centrals" in the trade, the supply being drawn from the tree Castilla Elastica.

In the East Indies rubber is being cultivated on a large scale, the plants having been transplanted from Brazil. In trade parlance the rubber coming from the cultivated fields of the East Indies is called "Ceylons," and sells in the market almost at the level set by the Para product.

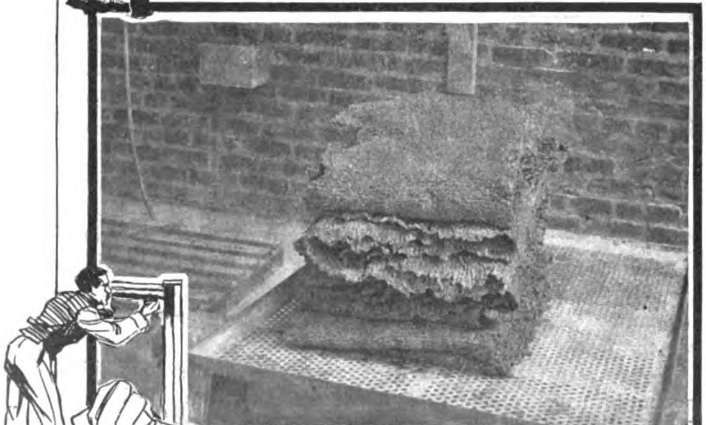
Peru contributes considerable rubber to the general supply, and Brazil, south of the Amazon, is gaining in importance. Madagascar and other tropical islands also produce some rubber.



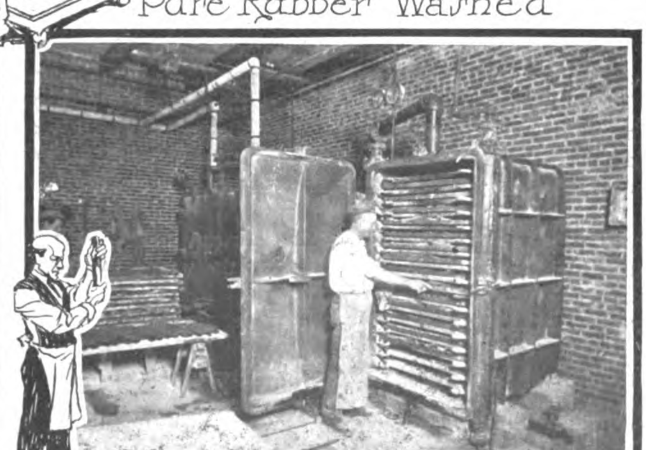
Last Stage of Washing



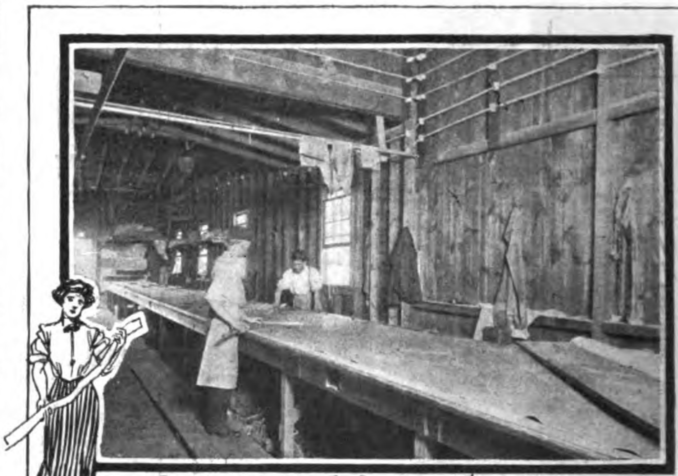
Washing Crude Rubber



Pure Rubber Washed



Drying Rubber After Washing



Cutting Fabric for Tires

Save in the cultivated plantations of the East Indies and to a certain extent in Central America, the process of drawing and collecting the latex or milk of the rubber-producing plants is the same as it was in ancient times. The laborer simply slashes selected trees with his machete, places half a cocoanut shell where it will catch the milk when it exudes from the wound and proceeds on his way. At regular or irregular intervals the workman goes over his route through the forest and collects the contents of the shells.

Contrary to the statements published in prospectuses issued by get-rich-quick concerns, rubber trees are not really mature until they are from 10 to 12 years old, despite the fact that vast returns are frequently promised after five or six years from the time of planting.

The rubber collected from individual trees varies in amount during a season and but a few ounces of the precious latex flows from the gashed bark into the ready shell between the time it is placed and the time it is collected.

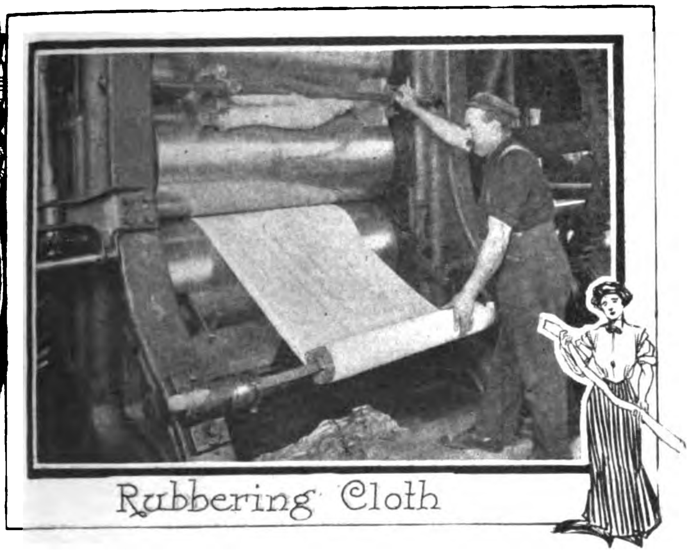
But in the course of his day's work it is not unusual for one man to bring in as much as 100 pounds of the milk.

Of course this does not apply to the plantations where the trees are cultivated, and the crop harvested by scientific means. There, modern machinery has been called into service and the yield of this variety of rubber is constantly increasing.

When the milk has been collected and brought into camp, the next step toward building an automobile tire is the process of smoking and shaping for shipment. A fire of certain grasses and nuts is built and the native workman dips a stick into the milky mass and then exposes the rubber to the action of the smoke and mild heat of the nut-fire. The surface of the rubber is hardened to a certain consistency by the fire and the workman plunges it again into the milk and replaces it in the smoke once more. This process is continued until the ball has grown to weigh from 100 to 200 pounds. When these balls are sliced in two to determine the quality of the rubber and to discover the presence or non-presence of foreign matter, such as stones, sticks, small animals or large vegetables, it is seen that the masses of rubber are in layers of various thicknesses, depending on the consistency of the milk when the mass was dipped and other factors.

Contrary to general belief, vast quantities of this raw rubber are imported directly from the Para fields into the United States. The idea that practically all the raw rubber of the world is shipped to England, Antwerp and Bordeaux is founded in error, for the customs statistics of the United States show that an increasing amount is brought here direct each year.

Rubber is bought by the tire factories, largely by sample, but sometimes on a definite guarantee as to what it will accomplish. With the terrific demand that is being exerted in the market the tendency is to emphasize the former practice and as a result, the buyers of tire-making houses are required to be the keenest sort of experts in their line.



Rubbering Cloth

Having received a shipment of crude rubber at his factory, the superintendent subjects it to the following processes: The split balls are first washed. This process is considerably more involved than the term might seem to imply, for the material comes to hand in the shape of masses that often weigh 100 pounds, when the work is being done with Para rubber. In the case of Africans, the form of the crudest stuff is irregular, varying from small balls to slabs and strings and somewhat similar shape as regards "Centrals."

The washing machines consist of a series of warm cylinders and the cleansing material is pure water. The appearance of the rubber before it goes into the bath is dark brown, with fairly smooth surface and a pungent odor that was given it in the smoke of the nut-fire.

It is rolled and washed and washed and rolled in the machines until all the sand, sticks, dirt and other foreign substances have come away, and then it issues forth in a band that may be as much as four feet wide. Coming from the rolls, the crude rubber takes the trade form of "crepe." It may be half an inch thick and is porous to a degree, somewhat sticky and is considerably lighter in color. This last quality, however, is temporary, for upon exposure to the air the "crepe" darkens somewhat under the action of atmospheric oxygen.

It then goes to the drying machines, where a percentage of the moisture contained in the "crepe" is extracted by gentle heat.

Coming from this process, the rubber is in the form of irregular masses and looks only remotely related to the perfected article.

The third step in manufacturing is to subject the product to the process of mastication. This is done with friction rolls, which reduce the mass to a condition of plasticity.

Having been reduced to small grains and shreds, the rubber is run between warm rolls and the admixture of sulphur and other vulcanizing chemicals is introduced. The mass is then rolled out and taken to the calenders or hot presses, where it is shaped into sheets. It is still crude rubber and at this stage of manufacture is called "mixed stock."

From there it goes to the making room, where workmen are ready to convert it into tires and other merchantable articles. In the process of tire-making there is another important element. By weight, automobile tires are composed of from one-quarter to one-third of the stoutest, heaviest kind of cotton fabric.

This fabric is not woven in the tire factory, but is purchased from the cloth weavers in large quantities. Each tire contains from four to six plies of this material. It is made of the longest and strongest fiber of sea-island cotton and in its condition prior to manufacture into tires it seems strong enough to turn buckshot.

Before the actual work of making the tires commences, great quantities of this cotton fabric are associated with "mixed stock"

The Moulds

Putting on the Tire

Joining the Tube

under the pressure of the rolls. When it is ready for tire-making, the cotton fabric is thoroughly impregnated with the rubber and each layer of the material is exceedingly sticky on one of its surfaces. It is called "friction cloth" at this stage.

The process of building a tire is then taken up. A layer of the friction cloth is laid on an iron mould and shaped to meet the various convolutions of the tire. Another is placed upon it and another and another, until the required thickness is secured. This, as has been said, is from four to six plies. On top of the cloth a thick layer of mixed stock is applied and then another single ply of the friction cloth. On top of this mass the main body of the rubber is placed. Tires vary in weight from about ten pounds to thirty-five pounds, depending upon size and amount of material involved.

The tires are shaped on the moulds by the workmen and when the correct size and shape have been given the tire is inspected by the superintendent and taken to the vulcanizer. This is simply a steam press where live heat can be applied to the articles to be made. The action of the heat is to change the chemical status of the rubber.

In the process of vulcanizing, quite a wide range of heat pressure and composition are used. A certain degree of heat is necessary for a certain length of time under certain pressure to get the best results from some of the varieties of work, while there may be a material difference in the treatment of others. The exact details are carefully guarded by the officers of tire factories with regard to the proportion of sulphur used and the intensity of heat applied in the process of manufacture.

Crude rubber freezes at about 40 degrees Fahrenheit and melts at about 120 degrees, but when the heat and sulphur have acted in conjunction to vulcanize the mass, the rubber is made almost impervious to ordinary temperatures. Of course it will still melt if enough heat is applied to it, and it will freeze under some circumstances, but the process of vulcanizing lends to the crude rubber the quality of permanency. It also increases the elasticity. While it is doing this, however, it has likewise taken away a large degree of its convertibility.

Experts say that once rubber is vulcanized it can never be reformed with the ease and satisfaction that were possible before. For this reason, automobile tires made of revulcanized rubber must of necessity be inferior to the goods made of crude rubber.

The finished tires are subjected to a searching examination at the factory and the usual percentage of defective tires so discovered is about 2 in 100.

Tires are tested with a pressure of about 400 pounds to the square inch in several of the well-ordered factories before being sent to the stock-room. It is said that the new tires will withstand a pressure of 1 500 pounds, but such a test is given them only on special occasions.

The making of inner tubes is a much simpler process than that of making the tire-shoes and outer tubes. The inner tubes are made of a single layer of pure rubber. While the delicacy of inner tubes has always been more or less of a problem to motordom, and while strength approximating that of the tire-shoe would be very desirable, such a thing has never been accomplished. A layer of cotton fabric, enclosed between two layers of rubber, would make a marvelously strong inner tube, but unfortunately the presence of the cotton in the mixture would defeat its own ends. The porous fabric would not be gas-tight for any length of time, if at all, and as that one quality is the foundation stone upon which all inner tubes rest, the idea is not regarded as practical.

In the fiscal year of 1909 33,000 tons of rubber, two-thirds of which was from Para, was imported into the United States During the fiscal year ending June 30, 1910, the imports into this country amounted to 44,000 tons, with the percentage from Para slightly less, although much more in actual pounds. The price this year touched $3.10 for the commercial grades of Para and at present the market is strong at about $2.

Foreign News of Interest

CONCLUSIONS OF INTERNATIONAL ROAD CONGRESS—RACE FOR LONG-STROKE MOTORS—EXPERIMENTING WITH THE GNOME MOTOR

MEETING for the second time, the International Road Congress has drawn up a number of conclusions relating to automobiles and the highway. It is of the opinion that touring cars do not cause abnormal damage to the roads providing their speed is moderate. No definition of moderate speed was supplied. Public service vehicles do not cause damage to the road if their speed is kept below 15 1-2 miles an hour, if the greatest axle weight does not exceed four tons, and if the charge does not exceed 330 pounds per centimeter width of rim, for wheels of 39 inches in diameter.

It was believed that commercial vehicles did not cause any damage to properly made highways whenever the following conditions were complied with: for vehicles on which the greatest axle load is 4 tons, where the speed does not exceed 12 miles an hour, and when the weight on the road wheels is not more than 330 pounds per centimeter width of rim for wheels of 39 inches diameter. Where the axle load is between 4 and 7 tons and the weight on the road wheels does not exceed 330 pounds per centimeter width of rim, no damage is done if the speed does not exceed 7 miles an hour. Where wheels of more than 39 inches diameter are employed, the load per centimeter width of rim shall be calculated according to the following formula:

$$c = 150 \sqrt{d}$$

in which d = the diameter expressed in meters, and c = the load expressed in kilogrammes. The congress believed that experiments should be undertaken to determine the maximum width of rim possible on motor vehicles in order to give an even distribution of the load on the road surface.

Ribbed metal tires were condemned as destructive under all circumstances. It was not believed that motor vehicles did any damage to curves provided the road was properly banked at these points and the speed was reasonable.

Long-Stroke Motors to Be Tried Out

The finest collection of long-stroke motors ever gathered in a single race will be seen at the Coupé des Voiturettes speed test to be held at Boulogne-sur-Mer, on Sunday, September 18. The entries are only 13 in number, with little probability of an important increase before the final closing; but what they lose in quantity they gain in quality. The race, which will be run over a hilly triangular course measuring 24 miles, with a total distance of 289 miles, is open to cars with a limited bore. Single cylinders must not exceed 3.9 inches cylinder diameter; two cylinders are limited to 3.1 inches bore; and four-cylinder models must not be bigger than 2.5 inches. Stroke is unlimited, and it is largely owing to this limitation that 2 1-2-inch motors will be produced capable of developing 40 to 50 horsepower, and able to hold their own against racers of three or four years ago having a bore of 6 to 7 inches.

Lion-Peugeot is favorite. The firm has two sets of cars ready, one of them being last year's models composed of two single-cylinder racers and one twin-cylinder V motor. The second set is entirely new and has not yet been seen on the road. The motors have the maximum bore of 2 1-2 inches and a stroke of 11 inches. This is a ratio of 4.3 to 1—the highest ever adopted for an automobile motor.

If there is time to properly tune them up for the race the new four-cylinder models will undoubtedly carry all before them. In view of competition, the firm has very little to say about the power they have been able to get on the bench. It is known, however, that the motor has its cylinders in one casting, multiple valves, and that it runs at over 2,500 revolutions a minute, with a piston speed of not less than 46 feet per second.

The most dangerous rival of the French car is the Hispano-Suiza, built in Spain. Like the Lion-Peugeot it has four cylinders in a single casting, with the maximum bore of 2 1-2 inches. The stroke, however, is slightly shorter, being only 7 4-5 inches. A very high engine speed is maintained, the makers admitting a piston speed of 45 feet.

The only other four-cylinder cars in the race will be supplied by Calthorpe, of Birmingham, England. While having the maximum bore, it is known that their stroke is short compared with that of the French and Spanish cars. They are not expected to make more than a regularity showing. De Bazelaire, Corre La Licorne, and D. S. P. L. will all put single-cylinder cars in the race. A formidable competitor is expected in the Corre La Licorne, with a motor built by Chapuis & Dornier, small motor specialists, and having a stroke of 11 inches for a bore of 3.9 inches. The others will use De Dion-Bouton motors of 3.9 by 10 inches bore and stroke.

Gnome Motor Being Renovated Mechanically

Experiments are now being made at the Gnome factory with a revolving air-cooled motor having mechanically operated intake vales. Up to the present all Gnome motors used on aeroplanes have been fitted with automatic intakes carried in the head of the piston. They have given satisfaction in working, but have the disadvantage of being inaccessible. To dismount them it is necessary to first lock the piston by means of a special tool, then unscrew the intake valve, together with its seating, by a special type of box key. This operation is naturally performed after the detachable cylinder head has been dismounted. As it is possible to screw out the intake without first locking the piston, it sometimes happens that mechanics do not follow the exact instructions for this work, with the result that whenever extra force has to be applied to move the intake valve the connecting rod is bent and the entire engine has to be dismounted. According to the makers, it is to overcome this difficulty, and not because of any dissatisfaction with the way in which the intake valves have done their work, that the mechanical type has been evolved. This latter has not yet completed its tests, and may, therefore, be further modified before being offered to the public.

The makers of the Gnome have secured two patents in connection with their valve mechanism, the first dealing with the method of mounting the valve in its guide and the second the operation of the two valves by a single overhead rocker arm. As on the standard type of motor, the cylinder heads are screwed home. The main rocker arm does not operate directly on the valve stems. It is composed of two parallel members united by transverse pins, and its outer extremity is balanced to equalize the weight of the push rod. Between the two members of the main rocker, and mounted on the same axle, are two auxiliary rockers of very open V-shape, one extremity of which carries a transverse pin acting as counterweight, and also reposing on the two arms of the main rocker; the other extremity receives the stem of one of the valves. The outer extremities of the auxiliary rockers are kept in contact with the main rocker by means of a four-blade flat spring; with the main rocker in a horizontal position both valves are, therefore, closed. The operation is as follows: On the upward lift of the push rod the outer extremity of the main rocker arm is raised, and by the same movement the auxiliary rocker is tipped, opening the intake valve. The pressure of the overhead spring keeps the exhaust seated. On the downward pull of the rod the inner end of the main rocker is raised and with it the secondary rocker operating the exhaust valve.

The cam mechanism has been entirely changed, for in place of the seven male and seven female ring cams, the valves are operated by means of a disc having on its face two concentric cam grooves into which fit "shuttles" carried on the face of the tappet rods. The disc is mounted on the extremity of the mainshaft, within the crankcase, and is driven by means of suitable internal gearing in practically the same way as the ring cams on the standard type of motor. This is a cam mechanism which has already been employed for automobiles, notably by Daimler, and for which no patent is possible.

Instead of the gas entering the crankchamber and being aspired through the valves in the pistons, on the new model it passes along the hollow crankshaft as far as the end plate, where it is aspired through the seven radiating intake pipes in the same plane as the cylinders, and connected to these latter by an aluminum elbow. This, by the way, is the only occasion on which aluminum is employed for the construction of the motor. The lubricating oil pipes are continued along the shaft to the bend, where they discharge their lubricant on the connecting-rod ends. Mechanical intakes should lessen consumption of lubricating oil.

New Epoch in Steel*

ELECTRICALLY REFINED STEEL IS REPLACING ACID OPEN-HEARTH PRODUCT, AND THE IDEA THAT THE CRUCIBLE PROCESS IS EXCLUSIVE FOR TOOL STEEL IS GIVEN A SEVERE JOUNCE

THE dawn of a new era in steelmaking is being heralded abroad, and automobile engineers who have struggled with this problem are awakening to the fact that "jewelry steel," so-called, is to be a regular product before the electrical process is, as might be stated, well in hand. In order to appreciate what the electric furnace is doing for the automobile steel situation, it will be necessary to relate the headway that is being made abroad, and to point out that nearly all German automobiles are now "sporting" electrically refined steel. But if the foreign fabricators of steel are taking kindly to the electrical process, it is also true that the American steel producers of this great commercial necessity are doing the same.

Just how the electric production of steel is to be of benefit to the makers of automobiles is a matter that cannot be elucidated without describing the process at some length, and stating the difference between it and the methods that were formerly relied upon for the fabrication of the better grades of steel. Steelmaking is conducted in the several ways as follows:

(A) Bessemer process.
(B) Basic open-hearth.
(C) Acid open-hearth.
(D) Electric furnace.
(E) Basic open-hearth with subsequent electric refining.
(F) Bessemer process with subsequent electric refining.

The reason why inferior steel is inflicted upon the maker of automobiles is because it is cheaper to produce, and the automobile man, if he is imbued with the economy idea, allows the price to run away with his judgment, or, if he is not well informed, the vendor of the poor grade of steel is enabled to reap a larger profit by selling the same, stating the while that it is amply good for the proposed work.

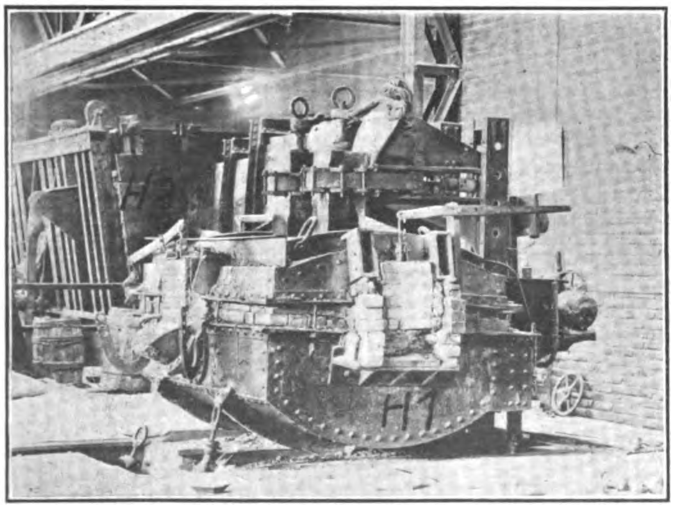

Fig. 1—View of a Héroult furnace. In the background is seen the tiltable acid open-hearth furnace from which the electric furnace is charged with molten steel

It is a fact, even if it is not well appreciated, that (in the absence of the electric refining, scavenging process) Bessemer steel ranks lowest in the scale of quality, but it is the most prevalent product and the easiest to procure. Basic open-hearth steel ranks next in the scale of quality, and next to Bessemer steel it is the easiest to obtain. Acid open-hearth steel ranks basic open-hearth steel about as much as the latter ranks Bessemer steel. Crucible steel, if it is as carefully produced as the process will admit of, takes rank with acid open-hearth steel, but if it is made in small quantities, under the most exacting conditions, may even excel. Electric furnace steel is not only taking high rank in the production of superlative brands of steel, but it is doing more. As a scavenging process, in an auxiliary capacity to the basic open-hearth furnace, or to the Bessemer process, this newer way of production is making great headway.

In times gone by, the electric process of producing steel was looked upon as a possibility, but there were many difficulties to be surmounted. A brief résumé of the history of the electric production would be incomplete without referring to one of the very earliest attempts, which was based upon the fact that electric energy may readily be converted into heat energy. It is of course known that:

$H = I^2 R\,t \times .24 =$ heat in calories.

In which,

$I =$ the current in amperes.
$R =$ resistance of the circuit in ohms.
$H =$ heat units measured in calories.

It may also be stated that:

$$I = \frac{E}{R}$$

$E =$ electromotive force in volts.

If an alternating current is used, the value of E must be taken as the square root of mean square of the instantaneous voltages, and the value of I will be represented by the square root of mean square of the instantaneous values of the current. The power factor must be noted and represented; it is 100 per cent. when a direct current of electricity is used, and less than this value when an alternating current is employed; just how much less is the point that must be determined; the power factor is equal to 100 per cent. minus the wattless component.

It may be taken for granted that a current of electricity offers a ready means of generating heat. The next point is to remember that the electric arc offers not only the source of heat but the necessary high temperature as well.

Merely having a high temperature available is scarcely enough for the best result. The electric arc offers more; the temperature is not only high but it may be localized; in other words, by proper manipulation the temperature in the slag may be brought to a higher level than that in the body of molten metal.

---

*Illustrations and data furnished by Jos. Shaeffers upon his return from Germany.

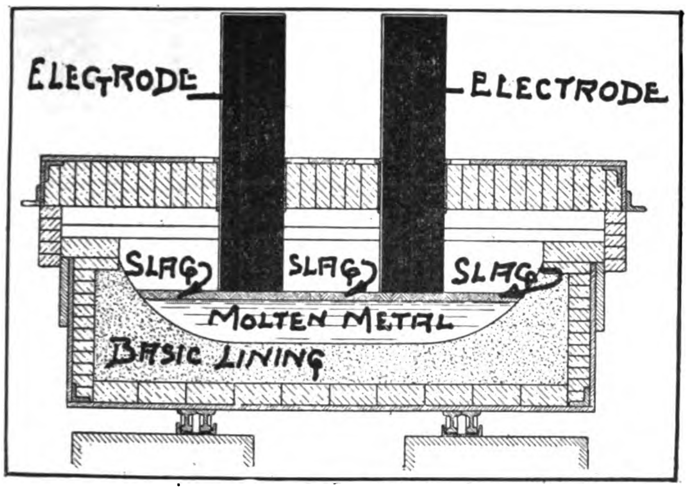

Fig. 2—Sectional view of Héroult furnace, showing layers of metal and slag during refining process.

From the experiments of 20 years ago as conducted in England, down to the process of Héroult, includes the history of a long series of experiments by the most advanced thinkers in the metallurgical field, calling into play a wonderful talent involving the application of the principles of electricity.

The general appearance of the Héroult type of furnace is shown in Fig. 1. This particular equipment is what is known as a 2-t Héroult-Lind furnace. It has the general appearance and many of the characteristics of a tilting type of open-hearth furnace. A section of this furnace is shown in Fig. 2. The two electrodes are each 8 inches square and 48 inches long; they are made of Acheson graphite. The length of the electrodes is sufficient to reach through the cover and dip into the slag, and it is obvious that by lowering the electrodes it is possible to cause them to dip deeper into the slag and even into the metal, and by this process change the main path of flow of the electrical current so that the greatest temperature may be either in the slag or in the body of the metal.

Referring again to Fig. 1 the Héroult furnace is marked H1, and just back of it a tilting acid open-hearth furnace H2 is located, the same being employed as a primary step in the process; the charge from the tilting open-hearth furnace is transferred to the Héroult furnace, where it is electrically refined.

The operation of the open-hearth furnace is no different from ordinary open-hearth work excepting that the process is stopped off as soon as the metal is reduced to the molten state. When the charge is transferred to the electric furnace the real refining begins and by way of a suitable precaution the bath is covered by a suitable thickness of slag which shields the bath from the carbon of the electrodes, some of which (in the process of wasting) remains, but it is mingled with the slag and thereby prevented from dissolving in the molten bath.

As Fig. 2 shows, the normal setting of electrodes is such that the arc is formed between the two electrodes, using the slag as the connecting medium. The heat of the arc is therefore at maximum, due to the high electrical resistance of the slag, and the distribution of heat is through the body of the slag, thence to the molten metal, thus affording a certain uniformity in the heat distribution. An automatic regulating device takes care of the distance between the electrodes and the bath; in the primary setting this distance is 1 3-4 inches.

An Intense Deoxidizing Process Is Carried On

The high heat in the vicinity of the arc induces an intense deoxidizing process which is so localized in the slag and spread out over the surface of the metal mass that the metal is not deteriorated. This process is brought to a complete state of perfection due to the fact that the bath is in constant and energetic circulation, which has the effect of bringing each particle of the metal into intimate relation with the high temperature for a sufficient length of time to complete the deoxidizing process.

The average temperature of the bath as a whole may not be any higher than the temperature as it obtains in other processes; it is the localized high temperature that seems to be efficacious. Deoxidizing is one of the beneficial processes; sulphur and phosphorus are both removed to whatever extent the manipulators desire, and carbon is regulated to a nicety.

Besides refining the steel, the electric furnace offers a most ready means of alloying; the distribution of the alloys is much more uniform and precise and the regulation of silicon, manganese, and carbon is brought down to a certain precision. Since there is no loss of metal to the slag after the same is transferred to the electric furnace, the process of alloying is relatively simple, it being only necessary to add the theoretically right quantity of the respective by-contents.

In the steel works of Richard Lindeberg, Limited, at Remschied-Hasten, Germany, the Héroult process is carried on as an every-day practical proposition, and the experience thus far gained would seem to support the contention that the excellence of the result is not at an undue cost.

Important Characteristics of Electric Furnace Steel

The specific gravity of the steel is higher than that of steel made by the other processes. For equal toughness the carbon content may be higher in this product; the effect of copper and arsenic is less pronounced. The ills attending the presence of sulphur and phosphorus are not so noticeable. Electrically refined steel behaves under the hammer and may be worked at a higher heat with less chance of deteriorating. Owing to the purity of the steel after it is subjected to the refining process it lends itself with great facility under specialized conditions as when it is desired to evolve a high silicon product; upwards of 5 per cent. silicon obtains in some of the brands of steel turned out. This process also works well in the production of aluminum steel; in some cases 2 per cent. aluminum is added.

It will be understood that this process is efficacious particularly in the production of chrome nickel steel and the other alloy products involving the use of vanadium, titanium, tungsten, and such other elements as are found to be efficacious for the purpose. The great purity of the product and the substantially complete elimination of sulphur and phosphorus have a marked bearing upon the procedure; moreover, super-oxidation may be resorted to if desired because deoxidation becomes the final corrective.

As an illustration of the efficacy of the process from the point of view of the removal of sulphur, references may be had to the following recount of the

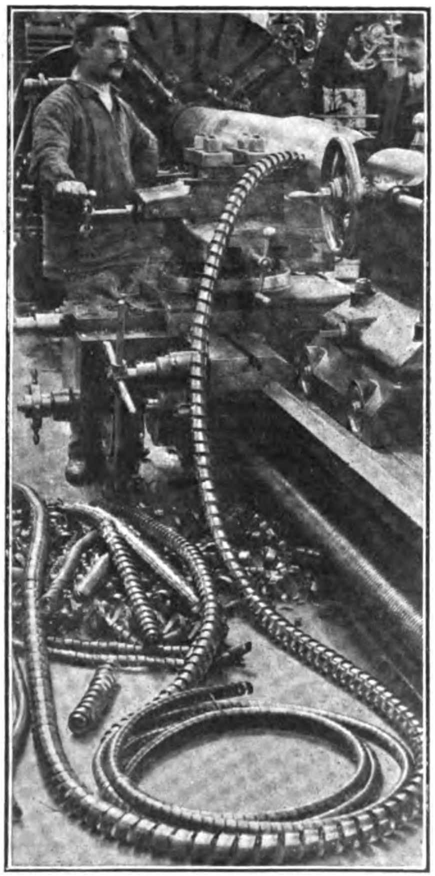

Fig. 3—Illustrating the cutting qualities of high-speed steel

final sulphur content as determined by analysis of 1,000 charges. Another table gives the analysis of electrically refined steel.

Don't

THIS ADDITION TO THE DON'T FAMILY DEALS MOSTLY WITH THE PURCHASE OF A SECOND-HAND AUTOMOBILE, LEAVING ROOM FOR A FEW INJUNCTIONS FOR EVERY-DAY USE AND A DASH OF HORSE SENSE FOR THE MAN THAT GETS IN WRONG FIRST AND THINKS AFTERWARDS

Don't forget that in polite society a second-hand automobile is called a "used automobile."

Don't overlook the fact that it may be a very much used car at that.

Don't think that a re-built demonstrating car, so-called, is a new automobile.

Don't become confused if it is said that the car is almost new and has not gone 1,000 miles—a precipice is not 1,000 miles down—but the going is such that the automobile that negotiates it will have a couple of broken ribs.

Don't look in the eye of the man that is telling you how good a second-hand car is; look in the eye of the car and see if it has a cast in it.

Don't try out your horse trading skill; what's the use of getting stuck?

Don't listen to the wiles of the man who says the car is almost new when the finish on the body shows that it has gone through the revolutionary war.

Don't forget that it takes time and service to make a log cabin look as if the resident has an ancestry—when an automobile looks that way it may have ancestral proclivities.

Don't add to your ancestors; an historical great-grandfather is a joy forever, but an automobile, if it belongs in that class, will be as sweet running as a threshing machine.

Don't let the demonstrator try out the second-hand car that you are to put your faith and your money in under an elevated railway; the elevator may make more noise than the car.

Don't persuade yourself that a car is making all the noise that it can when the demonstrator is nursing it along the boulevard at a low speed; try it out on high speed; give it a little cobble stone going; if it rattles like a saw mill purchase it as one if you have very little wood to saw.

Don't fail to test the car out on the several gears; it may not be silent on any of the gears excepting "direct."

Don't assume that the effect of noise is merely to be measured on a basis of its effect on your nerve; if you are a boiler-maker you can stand a lot of noise; the remaining fact is that noise is a sign of depreciation; remember that signs of depreciation would indicate to a Sherlock Holmes that there is a repair bill coming down the road.

Don't make haste in reaching the conclusion that silent performance is a sure sign of quality; the car may have been enjoined to be silent.

Don't forget that the rattling joints of a car, if they are filled up with paint, will cease to rattle.

Don't overlook the practice of putting bee's wax on the gears to silence them.

Don't go by the name plate; some wag may have replaced it by a more modern one.

Don't labor under the impression that a Worth sign on a costume makes it a Worth dress; the costume may have been made on the East Side. Likewise, an automobile may be disguised.

Don't think that a second-hand car is good just because it cost a lot of money in the first place.

Don't forget, the more the car cost in the first place, the greater will be the depreciation cost in the long run; if the depreciation is 10 per cent., for illustration, this percentage of $6,000 is $600, and a like percentage of $1,000 is but $100.

Don't overlook the fact that the depreciation of an automobile will be greater if the power plant is designed for high speed than will be true if the power available is barely sufficient to propel the car at an ordinary speed—the difference is very noticeable.

Don't allow yourself to get used to the idea that the compression of the motor is all right just because it cranks hard. A supply of heavy lubricating oil, put in on purpose, would produce this effect.

Don't be deceived; if there is a compression release on the car the demonstrator may be able to conceal the fact that the compression is far from good; he will point out that the compression should be slight when the release is used, as in cranking, but this will prevent you from finding out just how bad the compression is unless you try it when the release is not working.

Don't fail to remove all the lubricating oil, and after replacing it with a normal grade, determine what the true conditions of compression are; the power of a motor, as well as the fuel economy, increases with compression.

Don't purchase an automobile that is fitted with a clutch that will not take the automobile up a 20 per cent. grade; if the clutch will not hold, the power of the motor will be of no avail.

Don't fail to look twice at the clutch of the car if the same is "fierce." This may be a sign that the clutch is tightened up too much, just for the occasion—it might not hold in regular service.

Don't be satisfied with leaking valves; the leak may not be the sign of serious trouble; if the demonstrator says the valves can be ground in to make them tight, let him show you—the real point is, can they?

Don't invest in a car that has a cooling system that fails to maintain the normal working temperature of the cooling water. If the water boils when the car is standing at the curb, it is a sign that the cooling system is not what it should be.

Don't forget that the failure of the cooling system may be due to serious thermic derangement as well as a leaky pump.

Don't let the demonstrator convince you that cooling trouble is a slight derangement that can be remedied at the cost of a special delivery postage stamp—if he goes on that way, pay him the amount and let him do the work.

Don't permit the seller of the car to persuade you that ignition trouble is due to a set of depleted dry batteries—if he says that the ignition system will be all right as soon as the dry batteries are replaced by new ones, let him replace them and then show you how well the automobile will behave.

Don't fail to try out both ignition systems; this can be done in a very simple way: Run the car on one of the systems, and when it is performing well, throw in the other system and note the difference in performance.

Don't purchase an automobile that is not properly provided with brakes—it is your neck that is at stake.

Don't be induced to disregard the poor performance of the emergency brakes; the demonstrator may want to keep from you the information that they are faulty in design and cannot be made to work; if he says that 50 cents will re-line them and make them better than new, give him a dollar and turn him loose on the job.

Don't, just because the price sounds low, purchase an automobile that will not run; are you not aware that old iron is worth about one cent per pound?

Don't forget that an automobile is like a hound; if it cannot run it is scarcely worth feeding.

Don't fail to observe the condition of the springs; if they are in a state of "sag" it is easy to determine the fact; all that is necessary is to measure from the floor up to the underside of the chassis frame on both sides of the car; if there is a sag, one side will be down.

Don't fail to observe how much the front wheels wobble when the car is being driven along the road at a good pace; wobbling wheels are not to be tolerated; the trouble may be due to a fault in design as well as to lost motion.

Don't accept a car that has a worn-out steering gear; lost motion will tell the tale; if the demonstrator says it is but a trifle, and that it can be fixed, why beat him out of the pleasure of showing you just how clever he is?

Don't invest in a sagging live rear axle; if it can be fixed up let the seller do it. If it cannot be fixed, let the seller stew in his own juice.

Don't figure on the tires being of any value; they may be chalked up; it is possible that they were given hot water treatment before being put on; the inner tubes cannot be seen through the outer casings.

Don't fail to observe if the side-bars of the frame are in good order and free from a sag.

Don't fail to try the clutch lever when the emergency brakes are set; for all that you know, the brakes will interfere with the proper working of the clutch.

Don't reach the conclusion that all the possible troubles of the second-hand candidate are told here.

Don't be blinded by a lot of junk accessories—what you need is an automobile that will run, and in which some of the original sweet running qualities may still be discovered.

Don't be skeptical; there are good second-hand automobiles to be had—be diligent; scrutinize the entrails; if trouble is indicated, remember that you can scarcely be expected to see all of it; play safe in that event.

Don't conclude that a second-hand automobile is all right just because none of the troubles as here cited are not to be found; these are the troubles that belong in the automobile that you are not to put good money into.

Don't pay too much for a car that stands the light of a searching examination after it is found that it is free from impossible troubles—remember that it is still a second-hand car even if it does appear to be in an excellent state of preservation.

Don't monopolize the payment of tolls. Your friends may want to dig in their jeans once in a while.

Don't apply the brakes too suddenly on wet asphalt. The car is liable to go ahead anyhow if you do.

Don't try to show your car's paces on a tortuous downgrade. You may get your name in next morning's paper.

Don't try to "rush" a toll-gate. Suburban telephone companies are numerous.

Don't try to argue with a motor "cop." It only makes him worse.

Don't rely on your individual efforts in condemning bad automobile laws. Join some good club in your neighborhood and pay your dues regularly.

Don't wear your cap wrong-end foremost. It may give you a speedy appearance, but your eyes will suffer.

Don't start on a long trip without an extra pair of goggles in your kit. Eyes are too valuable to warrant taking chances with them.

Don't take both hands off the steering wheel to adjust your goggles. Telegraph poles and ditches are the automobile's affinities.

Don't pass another car at high speed. A slight miscalculation may prove costly.

Don't trail another car too closely, or you'll eat your bushel of dirt in too large portions for comfort.

Don't make up as a racing driver when you are on a pleasure tour.

Don't trust to luck to secure a rubber coat in case of rain. Take your own.

Don't delay too long in throwing in your low gear on a bad hill. You may stall your engine.

Don't try to get good results from an ignition system that is troubled with poor joints in the wiring; if the joints are soldered they will be barely good enough for their intended purpose.

Don't allow inertia of mind to stand in the way of inspecting the ignition system at frequent intervals; the wiring and connections need it.

Don't place $30 worth of tools in the tender keeping of a tonneau (under the seat) with the floor boards so loosely inserted that the tools will be scattered hither and yon along the roadside.

Don't forget that a file is the repairman's lathe, shaper, planer and milling machine. A good file is a very handy tool; all files are not good.

Don't be a pessimist when it is too late; if some gawk wants to hurrah money out of your pocket tell him to guess again.

Don't catch the enthusiasm of the fellow who has an eye on the yellow backs that persist in peeping over the gunwale of your vest pocket—why not have something to say about it; you are at least entitled to an opinion.

Don't grow weeds in your back yard and an account at a garage for car storage at the same time; put up a little garage of your own—the cost is but a trifle.

DISCUSSING MATTERS OF INTEREST TO USERS OF AUTOMOBILES; KNOCKS IN CYLINDERS; CORRECT PRACTICE IN DRIVING; DIFFERENCE BETWEEN HIGH-TENSION AND OTHER JUMP-SPARK SYSTEMS; HEATED MOTORS AND BOILING RADIATORS, ETC.

Loss of Power and Knocking on Grades

Editor THE AUTOMOBILE:

[2,361]—I have a new automobile and it seems to run very well indeed excepting when it is negotiating a long grade or when the road is soft and the pulling is unusually hard. It is a very annoying situation and I would consider myself much favored were you to give the matter a little attention. Last year when I wrote to you about other cases of trouble I had, the remedy that you gave me was to the point and it undoubtedly saved me many times the subscription price of THE AUTOMOBILE.

C. T. DEXTER.

Mobile, Ala.

There is not enough clearance between the pistons and the cylinder walls. Have the cylinders removed and rebored. The clearance should be on a basis as follows:

CLEARANCE REQUIRED BY PISTONS IN CYLINDERS

Bore of Cylinders In Inches	Clearance of Pistons At Top	Clearance of Pistons At Bottom
4	0.005	0.010
4 1-2	0.008	0.015
5	0.010	0.020
5 1-2	0.012	0.025
6	0.015	0.028

These allowances seem to be excessive and many autoists as well as some designers will generously disagree with the proposal. The fact remains that better results will follow if the pistons clear a little more than is to be expected when they are on the verge of sticking. It is not by having sticking pistons that compression is to be maintained. This quality follows when the rings are properly fitted.

A Few Special Situations Encountered in Driving

Editor THE AUTOMOBILE:

[2,362]—Like a good many other autoists of a relatively new vintage I know enough to keep to the right when going along the road; I also know that a road hog is not a good citizen; it is my intention to keep within the law, but I am not sure that I fully understand some of the more difficult situations that do occasionally arise. Will you please illustrate the correct practice under the conditions as follows:

1. When a car is approaching a cross street and it is desired to turn the same around.
2. When four cars come abreast; two going each way.
3. When one car is about to enter a cross street and meets another coming out.
4. When a car comes out of a street and approaches a circle, as at the Circle in New York City.

Brooklyn, N. Y.

The four specific situations are illustrated here and the captions under the illustrations will be sufficiently clear to eliminate the need of further elucidation.

High-Tension and Other Jump-Spark Systems

Editor THE AUTOMOBILE:

[2,363]—There seems to be a considerable amount of talk going the rounds about true high-tension ignition systems and other high-tension jump-spark schemes. Are they not, taking them as a whole, all high-tension jump-spark systems? If so, what are the distinctions that have to be made in properly describing them? It is believed that THE AUTOMOBILE is the one paper in the country that is capable of, and fearless enough to state the facts even though there may be some trade secrets involved. In any case why should there be any trade secrets? Is it not right that a man should know what he is getting when he pays good money for it?

GEO. W. PEABODY.

Plainfield, N. J.

Talk is cheap. When a company goes to the cost of building a device and exerts itself sufficiently to attract the notice of a clientèle, it stands to reason that it can scarcely hope to evade publicity, and knowing this, there is little chance that it will build any device that it thinks is below an acceptable standard.

Every ignition system that uses spark plugs in the cylinders, of the character that furnishes the spark by the jumping of the electrical charge across a fixed gap, is a true high-tension system.

All high-tension jump-spark systems of ignition are not made in the same way. There are two principal subdivisions, *i. e.*, (a) the system that uses high-tension magnetos as the source of electrical potential and (b) systems that employ step-up transformers in conjunction with low-tension magnetos.

The high-tension magneto system, as depicted in Fig. 5, differs from the step-up transformer system, structurally, due to the fact that the armature of the magneto has a double winding, the idea being to generate a low-tension current in the coarse wire winding, and step it up to a high potential in the fine wire winding of the armature. This plan eliminates the use of the separate step-up transformer for the reason that it is embodied into the construction of the magneto itself in this way.

In the second type of ignition equipment, the armature has a low-tension winding, and the terminals of this winding are connected up to a separate step-up transformer as shown in Fig. 6.

Both systems, according to this reasoning, have provision for generating a low-potential wave, and employ a transformer to multiply the voltage of the wave; that is to say, a secondary winding, on the principle of the transformer, is used to step the voltage up to some higher level.

The difference, in point of principle, is that in the magneto that is self-contained the coils are all on the armature, whereas the remaining type of magneto has a separate system of coils to perform the secondary function.

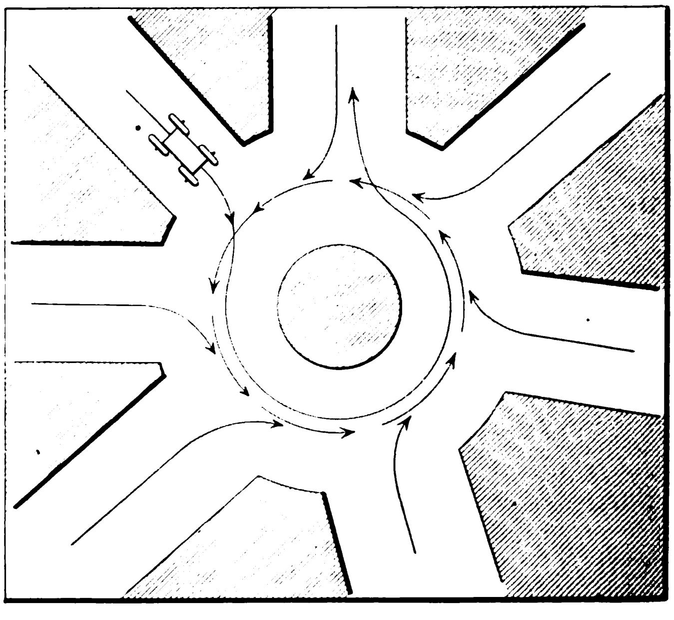

Fig. 1—Arrows point the way to an automobile that approaches a circle, coming in from any one of the converging streets or avenues

Which is the best system? Such a question is more or less foolish. The general principle is the same in both cases. One slight difference should be noted, *i.e.*, when the secondary winding is placed on the armature of the magneto, it cuts the magnetic flux and would generate the electromotive equivalent due to the number of inductors employed even were there no primary coil employed.

In the meantime it is within the realm of belief to take up with the idea that most of the troubles that are experienced with ignition systems are due to causes that are not due to any violation of magnetic principles, basically. The faults are of detail.

Motor Heats and Radiator Boils

Editor The Automobile:

[2,364]—I have a car that seemed to work very well when I purchased it and the demonstration, which was long, certainly did not disclose anything of the trouble that I am now experiencing. In a short time after I take the car out on the road the motor shows that it is heating up, and during the day I have to fill the radiator three or four times. Certainly this is not the performance that I had a right to expect from the car when I purchased it and I am much disappointed as you can readily appreciate. The agent who sold the car to me does not seem to be very sympathetic and he as much as said to me go and learn how to drive; the trouble is in you and not in the car. Do you think this is fair treatment after taking my money?

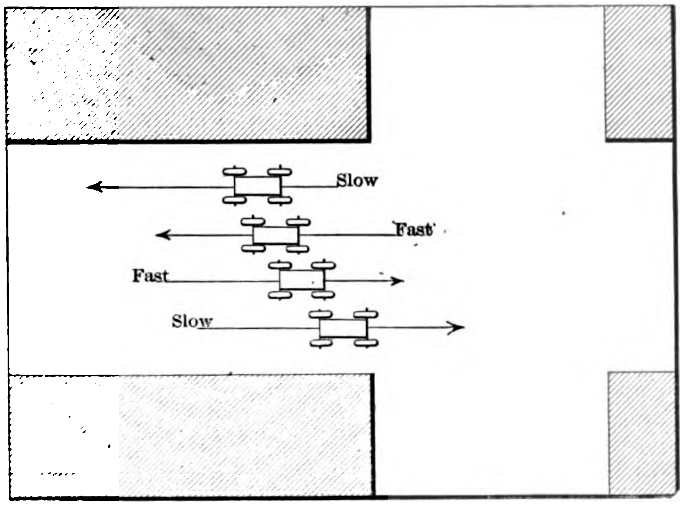

Fig. 2—Presenting four cars abreast, two traveling in each direction; indicating that the two outer cars should go slow to permit the two inner cars to get by and out of the way

New Subscriber.

New York City.

When the agent took your money you took his car; a fair exchange is no robbery. Sympathy, of the kind that you want, costs money. The agent's profit is probably not enough to encourage him to reduce it in the way that you would suggest. When he told you that the trouble was in you rather than in the car, strange as it may seem to you, he was telling the truth. The fact of the matter is that you persist in running the motor on a retarded spark. Advance the spark so that the motor will not heat up, and if the car does not then run slow enough to suit you, change to a lower gear. Throttle down on the mixture a little, and it will also be of advantage to you to reduce the flow of gasoline at low speed. Too much gasoline is likely to cause over-heating.

What Is a Good Practical Timing for a Motor?

Editor The Automobile:

[2,365]—Since I purchased my automobile two years ago I have gone over the timing of the opening and closing of the valves three times and I want to say that it has been a beneficial practice taking it on the whole. I did not wait until the motor showed distress; it is my belief that it is not good practice to get into trouble even without thinking of how to get out again. When I purchased my car and brought it home to my little garage, the first thing I did was to check over the timing of the valves, and I found that they were not all timed alike. I did not get vexed and go back to the agent for redress; what I did say to myself was, if the motor was not properly timed when the agent said it was in the pinkest of condition, why should I take the car back to him and risk having it put in worse shape than I found it. If the agent was that kind of a man it was enough to find it out and keep away from that grade of smallpox. Moreover, the automobile was a good one in spite of the shortcomings of the agent.

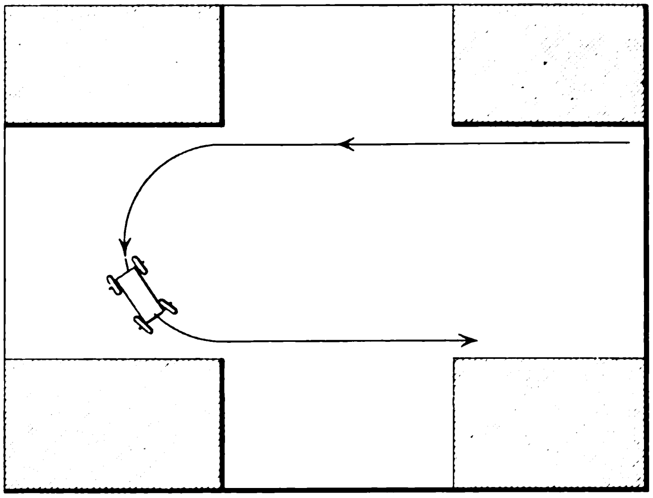

Fig. 3—When a car is going in one direction and it is to be turned around; the figure indicates that the car should go by the lateral before turning around

My first try at timing was not much of a success, but I made the car run better than when the agent handed it to me. What I then did was to find out how each valve was timed and I took a mean timing, that is to say, the average of the variations as I found them in the car. After that I went into the matter at some length and learned how to deftly manipulate the mechanism. With growing confidence I retimed the valves and the situation was improved quite noticeably. The motor "kicked along" for more than a year on this second timing, but the day finally came when I considered that the motor was getting short of breath, and I went at it again—the result was very good.

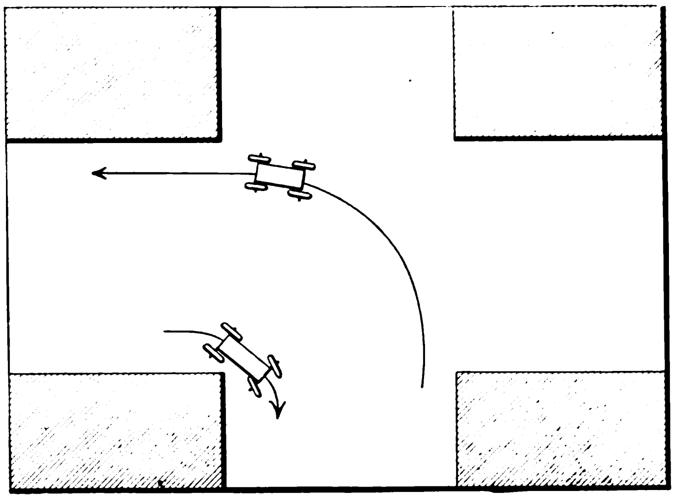

Fig. 4—A car coming out of a lateral and another going in; it is not only desirable to go slow, but it is also proper to keep well to the right of the street

It occurs to me now that I may have been over-confident after

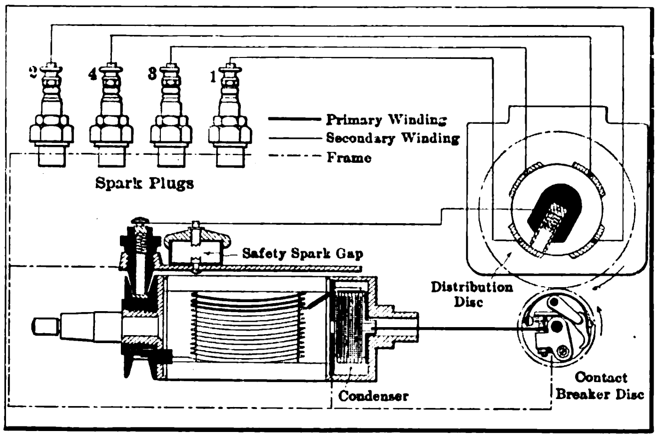

Fig. 5—High-tension jump-spark ignition system using high-tension magneto

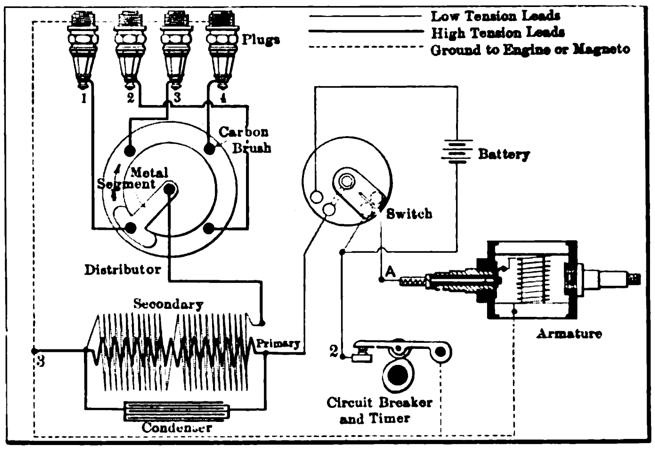

Fig. 6—High-tension jump-spark ignition system using low-tension magneto

all; perhaps there is a better timing than that which I use, at all events I will be glad to do the work if you will direct me.

Alex. D. Mansfield.

Buffalo, N. Y.

So brave a motorist is hardly in need of any help at all. The probabilities are that the timing is quite up to the best requirement. The following is considered a good setting of the valves of a motor that is to perform flexibly, running at a maximum speed of 1,300 revolutions per minute:

SATISFACTORY TIMING OF VALVES CONSIDERING FLEXIBLE WORK

Lead of Exhaust Opening	Lag of Inlet Closing	Lag of Exhaust Closing	Lag of Inlet Opening
44	33	10	17

It will be understood that the figures are in terms of degrees as marked off on the flywheel of the motor.

Some motors fail to work satisfactory when the inlet is opened close to the closing of the exhaust; if the design is such that it is feasible to open the inlet earlier it will be desirable to do so.

There is quite a little in the question of timing a motor in a way to conform to its characteristics, but this is a detail that must be taken care of alongside of the fact that the motor must be used in the service for which it may be designed. If a motor is designed for one purpose and used in some other work, it may be better to so time the same that it will lean toward the intended result—the value of the service will, of course, fall short of the maximum obtainable when best conditions are satisfied.

Clutch Spinning Interferes with Sliding of Gear

Editor The Automobile:

[2,366]—I have just purchased a new automobile and since it is my third car I have some idea of how the gears ought to slide. What I find is that the clutch has to be slowed down before I am able to change gears and a pause is necessary. The trouble is that the pause is too great and I would like to have you tell me of the reason. The clutch is of large diameter and looks quite substantial; it is of the leather-faced cone type.

Subscriber.

Hagerstown, Md.

The clutch is of such large diameter and so heavy that the energy stored in it is more than can be disposed of in a short time. It is impossible to slide the gears before they are reduced to nearly the same speed and the flywheel effect of the clutch interferes with this demand. There is only one way to apply a remedy and that is to attach a "drag" to the clutch. This can be done by finding a surface for a small brake-shoe and figuring out a motion for manipulating the same. The drag should come on just as the clutch is released. Cork inserts in the face of the drag will make it work better than it will if the contact is metal to metal.

Questions That Arise

CONCERNING THE PROPER SIZE OF A CARBURETER IN PROPORTION TO THE AMOUNT OF WORK IT WILL BE CALLED UPON TO PERFORM—TESTING OF GNOME MOTORS

[223]—What is that fixes the ultimate size of a carbureter?

The capacity of the same for delivering gasoline to the train of atmospheric air on a basis of 8,000 volumes of air at a pressure of one atmosphere to one volume of liquid gasoline at the same pressure, assuming the design of the carbureter is such that the liquid gasoline is vaporized and mingled with the air before the same reaches the combustion chamber of the motor.

The best test to make to ascertain whether or not the carbureter is large enough for a motor in a specific instance is to take the automobile to a road that has a 20 per cent. grade that is long. Start the car up the grade at its maximum speed and slide to low gear, keeping the motor going as fast as possible and the car climbing as fast as it will go. If the carbureter is too small for the motor, the latter will drink up all the gasoline that the carbureter will supply, and, as the demand will then exceed the supply, the motor will then stall.

This is a dangerous situation and it is one that should be examined into by every autoist in order that he will be able to judge of the mountain climbing ability of his automobile before he entertains the idea of making steep ascents.

There is a secondary reason for failure of the system of carburetion on long steep grades. If the gravity principle of feed is used and the "head" is restricted, it is just possible that this head will be reduced by gradient so much that the pressure back of the flow of gasoline will fall off to zero. This idea is illustrated in Fig. 1. Obviously, the shorter the distance L the less will be the trouble from this quarter, and if the gasoline tank is directly over the carbureter the difference in the head due to gradient will be almost nothing. As the illustration shows, if the grade is such that the line designated as level changes to the position designated as grade, the head will change from the original difference, as indicated in conjunction with the level line, to zero, as indicated in conjunction with the grade line; at this instant the gasoline will cease to flow to the carbureter unless the tank is more or less full, when the difference in head will be directly proportional to the height of gasoline in the tank.

But this is a bad state of affairs; the pressure on the gasoline will then change with the quantity of gasoline in the tank, and while it might flow fast enough to afford some result on a level, it might so limit the capacity of the carbureter just when it should be a maximum that the motor would be stalled. Now, it is not dangerous, as a rule, to have the motor stall when the road is level, but when a car is going up the side of a mountain it is far from pleasant to contemplate the idea that the power will cease and the motor will back down the steep declivity unless the brakes hold. Of course the brakes will hold if they are in good working order and properly designed. But are they always in good working order? Are they invariably properly designed? How many motorists can write in to the editor and say the brakes on my car, especially the emergency system, will not stop or hold my car?

[224]—What is the prospect from motors of the type known as the Gnome? Does it offer any attraction to the maker of automobiles? If it is light and powerful it should offer possibilities.

During the official tests held at the laboratory of the Automobile Club of France the new Gnome 14-cylinder, 100-horsepower motor failed to give the results claimed for and expected of it. The motor consists of two groups of 50 horsepower each connected up to a two-throw crankshaft, the explosions of the front and rear motor taking place at 180 degrees in relation one to the other. The cylinders measure 4 3-10 by 4 7-10 inches bore and stroke, and are cooled by revolving, together with the crankcase, around the fixed shaft.

The first test lasted 28 minutes 32 seconds, being stopped by the breakage of an intake valve spring. During the first 15 minutes the motor averaged 76.1 horsepower, at a speed of 1,128 revolutions; during the remainder of the time, at 783 revolutions a minute, the average power was 25.6 horsepower. During the 28 minutes 32 seconds the motor was under test its average speed was 1,004 revolutions a minute; average power 52.97; total consumption of gasoline 5 kilos 700 (12.7 pounds); total consumption of lubricant—castor oil—4 kilos, 400 (9.6 pounds); specific consumption of gasoline per horsepower-hour, o kilo, 226; specific consumption of lubricant per horsepower-hour, o kilo, 174; weight of the motor, 304.6 pounds.

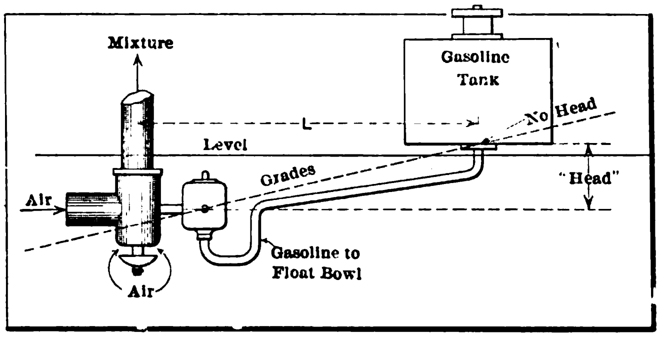

Fig. 1—Showing the influence of grades on the flow of gasoline from a tank under the influence of gravity

A second trial was stopped at the end of 59 minutes 3 seconds by reason of the breakage of two sparking plugs. On the third test the motor was stopped voluntarily and at the request of the owner at the end of one hour. The average speed and power for each 15 minutes were as follows: 1,135 revolutions, 74.40 horsepower; 1,112 revolutions, 69.90 horsepower; 1,100 revolutions, 67.78 horsepower; 1,098 revolutions, 67.58 horsepower. The average speed during the one hour's test was 1,111 revolutions a minute and the average power 69.89 horsepower. The consumption of gasoline for the hour was 22 kilos 700 (46.6 pounds); total consumption of lubricant, 11 kilos (24.2 pounds); specific consumption of gasoline per horsepower-hour, o. k. 324 (0.71 pound); specific consumption of lubricant per horsepower-hour, o. k. 157 (0.34 pound). The total weight of motor 304.6 pounds; weight per horsepower, 4.5 pounds. The tests were made on the first motor of this type produced at the factory. In their own works 95 horsepower had been obtained.

The only other competitor in the same category was a revolving 2-cylinder air-cooled Farcot motor which stopped dead at the end of a few minutes by reason of the seizing of an aluminum piston.

Digest

EXTRACTS ON TECHNICAL LINES FROM FIFTY BEST FOREIGN PAPERS—THE INFLUENCE OF A SECOND DIRECT DRIVE TO MAKE THE OPERATION OF A VEHICLE CONVENIENT AND ECONOMICAL IN HILLY DISTRICTS—AN EXPLANATION OF THE VAGARIES OF CARBURETERS

The transmission with two direct drives gives different results.* Let the gear speed ratios be supposed to be as before. Vehicle B can then scale the 5 per cent. hill on the third speed at about 36 kilometers per hour, which means a gain in speed of 8 kilometers and a smaller fuel consumption.

If instead of four gear speeds only three are available and their ratios are: first to second as 0.50 to 1 and second to third as 0.57 to 1, vehicle B is still more at a disadvantage; it can climb the 5 per cent. grade only on the low speed at 16 kil. per hour.

As has been seen, vehicle A could climb a 7 per cent. hill without changing gear, but rather slowly, at 28 kilometers per hour, but the 5 per cent. hill it climbs at 38 kilometers, the 6 per cent. at 42 kilometers. Evidently there is no advantage in changing gear for the 5 per cent. hill. In fact, if there is only one direct drive, the motor on reduced gear would develop only 14 horsepower at the rim, while, going at 58 kilometers per hour and direct drive, the power at the rim is 17 horsepower, so that there would be a loss in changing gear. The situation is similar for the 6 per cent. hill; it can not be scaled faster than 42 kilometers per hour, whatever we do, unless there is a second direct drive to save the efficiency of the transmission. The 7 per cent. hill can be climbed on the third at 35 kilometers, which is a gain of 7 kilometers per hour. With a second direct drive, the 5 per cent. hill could be scaled at 61 kilometers, which would be a small gain, hardly compensating for the manipulation of the lever, but the 6 per cent. hill may be taken on the third speed and direct drive at 56 kilometers, which is a gain of 14 kilometers over the third speed, by interposed reducing gear, and the 7 per cent. hill can be scaled at almost 50 kilometers by direct third-speed drive, which is a gain of over 20 kilometers compared with the direct high speed and of 15 kilometers compared with third speed by reducing gear.

While it is understood that, on level roads, the comfort of operating a car with few gear changes depends mainly upon the flexibility of the motor, the examples presented show that in traveling over a hilly territory the comfort in operation is nearly independent of the flexibility of the motor; that is, the motor may be highly flexible and the vehicle may, nevertheless, exact many manipulations of the speed lever, or the motor may be lacking in flexibility and the vehicle yet very comfortable to operate. The runabout or the torpedo type will always be more agreeable to conduct for this reason than a heavy limousine (of equal power) and, while the lighter and less bulky vehicles may get along even in moderately hilly districts, such as Normandy or Touraine, with three speeds and a single direct drive, the limousine placed on a chassis of equal power demands four speeds, and the two highest with direct drive, in order to make

---

* Continued from last week.

the vehicle more rapid, easier to operate and less wasteful of fuel. The builders in the Lyon district, which is especially mountainous, have long ago come to the double direct drive. Cottin-Desgouttes, Pilain, La Buire and Berliet have two direct drives. Pipe also constructs his transmission box with two direct drives.—C. Faroux in *La Vie Automobile*, June 4.

All automobilists have observed that carbureters work differently according to the season, the condition of the atmosphere and, on the same day, according to the hour and the temperature. In passing through a forest, even those least alert discover that the vehicle becomes imbued with a responsiveness which it did not possess a moment before. The author has taken pains to seize these differences by accurate and prolonged observation in practice. For one year almost daily he passed through 15 kilometers of forest. Often, he says, during the heat of Summer, the vehicle would run sluggishly or even badly, over an overheated road, toward one o'clock in the afternoon, but as soon as the forest was reached the motor picked up and the gait was quickened, without the carbureter being touched. Also, morning, evening and night gave better motor results than the heated hours of the day on any road.

At the aviation meet at Vichy, last July, on an apparently perfect day, large masses of spectators waited in vain from ten o'clock in the morning to 7:30 at night, and became quite violent and abusive, seeing no reason why flights should not be made. But in reality the carbureters could not be made to work properly on any of the machines, as the day was tropically hot and the territory denuded of all trees. But after sundown the aviators took out their machines and made the evolutions expected of them. Two explanations have been offered for the peculiarities mentioned. One ascribes them to the chlorophyllian vapors of forests, but must be rejected, since it does not explain the morning and evening effects where no trees are present. The other explains them by the variations in humidity which follow variations in temperature, and seems plausible for the Summer, but conflicts with the facts noted in Winter. As soon as the coefficient of humidity becomes pronounced in Winter, as it easily does because very little water vapor is required to saturate cold air, the carburation becomes less good. And it seems unreasonable that water vapor should be beneficial in Summer and harmful in Winter.

Some of the facts of combustion in cylinders throws light on the subject. To burn gasoline completely there is required at least 15 times its weight in air. Tho quantity of air used greatly influences the heat of the combustion. According to Claudel, the theoretically best mixture gives 2,788° centigrade. With one and one-half times more air the heat drops to 1,951°; with twice as much air to 1,488,° and to 1,010° with three times as much air.. The thermic efficiency will then, other things equal, be more perfect the more nearly the air is supplied in the proportion of 15 to 1, weight units. Any variation in the proportion must be of importance. The carbureter is the instrument by which the proportion is regulated. In principle it maintains the fuel at a constant level by means of a float and delivers the gasoline at a jet whose mouth is slightly above the level of the liquid. With the customary means for regulating the auxiliary air admission, the carbureter should maintain a constant mixture, but all who have used carbureters whose auxiliary air intake is controlled by a special finger-lever know that it is often necessary to operate this lever without any cause for so doing being apparent. The physical condition of the surrounding atmosphere seems to influence carburation, and as the variations are particularly noticeable in the Summer between the hot and the cool hours there is reason for inquiring how the atmosphere behaves during these periods. First, the hygrometric state is variable. In general the air contains more water vapor in summer than in Winter and is nevertheless less humid because it will hold more before saturated. Humidity depends not on the quantity of vapor, but on its condition. In the Summer the cool mornings and evenings have less vapor, but more humidity than the hot hours, and this has given color to the hygrometric theory, which nevertheless must be rejected because humid air under other circumstances carburates poorly, and because a theory which fits better is available. In our climate the air is seldom saturated with water vapor except during fogs and thaw. It contains on an average one-half of the vapor necessary for saturation. On this basis the most favorable hygrometric condition, for a summer evening. should correspond to a temperature of 20° centigrade, with about 7 grammes of water vapor for each cubic meter of air, which is in the proportion of 1 to 170.

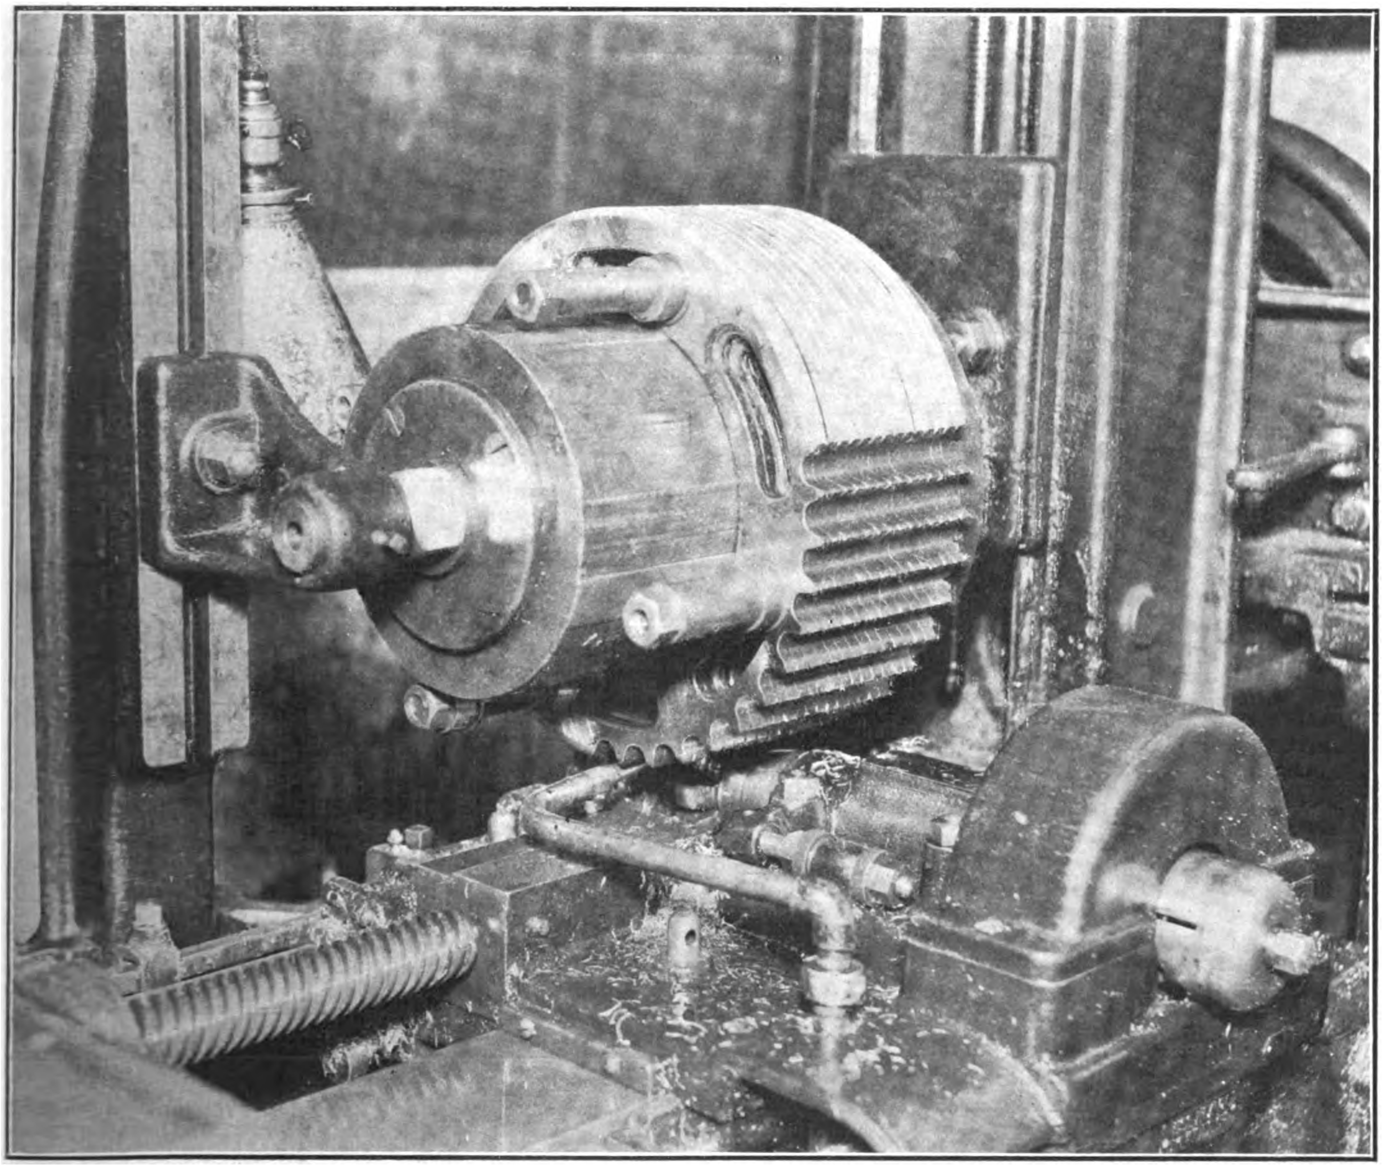
On the other hand the barometric pressure also varies, according to the hours and inversely with the temperature. The Summer air is less dense at noon than at night or in the evening, as a rule, by reason of the heat of the sun, which gives rise to expansions and thereafter to contractions, and consequently to changes in density. The influence of density must be real, because it has been verified in the case of gas motors. These industrial engines give 10 per cent. less power at an altitude of 1,000 meters than at the level of the sea. The daily variations of the barometer, being within much narrower limits, would not at this rate alone account for the variations in motor power, but in conjunction with certain other facts they form the basis of a provisional theory which the author has tried to verify by experience.

The volatile liquids used as carburants produce vapors whose tension grows in a geometric progression with the temperature. If the tension of the vapor is equal to a column of mercury 100 millimeters high, at the freezing point of water, it exceeds 3,000 millimeters at a temperature of 100°. Further, the volatility of gasoline is extremely sensitive and is affected by very slight disturbing factors. Evidently, the gravitation of the surrounding air must have a positive effect in deciding the depression of the gasoline in the jet of the carbureter, and, in turn, the smallest variation of the depression affects notably the quantity of liquid drawn out and vaporized. And, since the tension of the vapor is so much higher in warm weather. the effects are so much more noticeable in summer. Assuming a well-conceived carbureter functioning properly under any barometric pressure, when this pressure diminishes even slightly the gasoline will come out more abundantly, the best proportions of the mixture will be changed by an excess of gasoline and reduction of the air, and there will be a less efficient motor action. Finding no means for acting upon the emission of gasoline or upon the physical condition of the surrounding atmosphere, the author relates how he chose to act upon the nature of the fuel by reducing its sensitiveness and the tension of its vapors. In this he was guided by two laws: (1) when a liquid holds any foreign substance in solution the tension of its vapors is smaller than in a state of purity and so much smaller as the solution is more concentrated (nearer saturation); and, (2) when the dissolved substance is itself volatile the tension of the mixed vapors which are produced is less than the sum of their respective tensions. He relates the difficulties experienced in finding suitable substances for admixture, and cites the practical results obtained with various cars after finally deciding in favor of a substance which he calls Robur, but the composition of which he does not divulge, because it represents the commercial result of his research.—G. Patrouilleau in *La Technique Automobile et Aérienne*, August 15.

A varnish which keeps metals highly reflective and which applied to the parabolic surfaces of projectors at lighthouses or in automobile lamps saves both work and efficiency, has been produced and marketed under the name of "Camt." It is obtained by dissolving a gelatinous lacquer at high temperature in amylacetic ether with the addition of a siccative, and becomes very hard and quite impervious to water. It is applied cold without any preparation and dries in a few hours, forming an exceedingly thin and absolutely invisible film through which the metal shines with all the polish that has been imparted to it. While this new varnish may be washed with impunity it will not stand much rubbing, and is therefore of no great value for metallic automobile parts which are constantly subject to handling.—*Omnia*, July 30.

Among the Makers

CARS SHOULD BE MADE ON A DUPLICATING BASIS TO INSURE REASONABLE REPAIR COSTS—STODDARD-DAYTON LINE FOR 1911—THE HAZARD MOTOR



Depicting cutting of teeth of gang of sprocket wheels in Woods plant, using automatic gear cutter

EVERY experienced autoist realizes that it is of great advantage to have a car that is made on a duplicating basis in order that repairing may be done at a reasonable cost and on a basis that will maintain the car up to the original standard.

Quality, as it resides in an automobile, must be measured from two points of view: If the original automobile is thoroughly good, but repair parts cannot be had, the purchaser will be in a worse predicament than if a cheap and relatively poor automobile is purchased, due to the fact that the good automobile, assuming that it is high-priced also, will have an enormous cost per car mile in service. If repair parts are readily obtained and the purchase price of them is reasonable, the purchaser is then placed in a position to speculate to the extent that he will have to determine for himself whether or not a very high-priced car will be the best in the long run, or to what extent the purchase price can be shaded, remembering that repair parts can be procured when wanted, and at a price that is attractive.

The real problem is to be able to make automobiles, sewing machines, battleships, or any other character of a machine on a duplicating basis. Come to think of it, Nature did not set a good example in this regard. It is quite well understood that in Nature there are few duplicates; it might be said there is a marked and striking difference between blades of grass, babies, mountains, bandits, and even machinists—Nature goes in for variety.

The obstacle to duplication lies in the enormous cost of making preparation for duplicating parts. The cost of gigs for a single model of a car is not far from $50,000; under most exacting conditions, even double this sum.

It must be remembered that this cost would be the same no matter how many cars of the same model might be turned out; it would be $50,000 for one automobile and it would be the same amount for any greater number.

Some relief has been realized by ganging the work; in other words, special tools are made for the purpose of doing a single operation on a large number of parts instead of upon one part. In some instances the tools are so made that they perform several consecutive operations upon a considerable number of parts at a single setting.

Accuracy, as it is induced by the use of special tools, is foreshadowed in the tool room; the most skilled artisans are there employed and they are directed by the best talent that a diligent search can uncover.

Stoddard-Dayton for 1911

A FEW CHANGES AND MANY REFINEMENTS MARK THE LINE FOR THE COMING YEAR—26 MODELS OF PLEASURE CARS AND 3 OF COMMERCIALS

FEW American makers of automobiles offer their clientèle such a wide range of choice in models, styles and prices as does the Dayton Motor Car Company, of Dayton, Ohio, in announcing its 1911 line. No less than 26 separate and distinct body models of pleasure cars, of four different sizes of power plant mounted on six chassis, are listed, not to mention three commercial cars. The pleasure cars are divided into four classes, as follows: Stoddard-Dayton "50," ten models; Stoddard-Dayton "40," seven models; Stoddard "30," six models, and Stoddard "20," three models.

In the closed-car section the company's line is particularly strong, there being two styles of limousines in the "50" class (one with fore-doors) and a beautiful landaulet. In the "30's" there is a limousine, a landaulet and a coupé. All these closed models are, as usual, most excellent examples of the body-maker's art, finished within and without with an elegance and an attention to detail in the little niceties and conveniences of furnishing that stamp them as the best specimens extant of American workmanship along those lines. Auxiliary seats are part of the equipment of all closed-body cars, and when not needed they fold completely out of the way. Closed cars are furnished in any combination of colors desired and upholstered to suit the individual taste of the purchaser in broadcloth, leather or Bedford cord.

Among the changes noticed in the 1911 models is the increase of the length of the wheelbase of the "50" chassis from 128 to 130 inches; that of the "40" from 116 to 120 inches, and of the "30" from 108 to 114 inches.

The limousines, landaulet and touring car in the "S-D 50" class have seating accommodations for seven passengers each, as have the limousine and landaulet in the "S-30" division. The "50" Torpedo and 11-K, the "40" touring cars and 11-C, the "30" touring cars and the "20" touring car carry five passengers each.

*Two or four d

The "50" 11-K, the "40" 11-C and Torpedo, the "30" Coupé and the "20" Touring-Roadster each has accommodations for four. All the remaining models carry two with the exception of the "50" Roadster, which has seats for three.

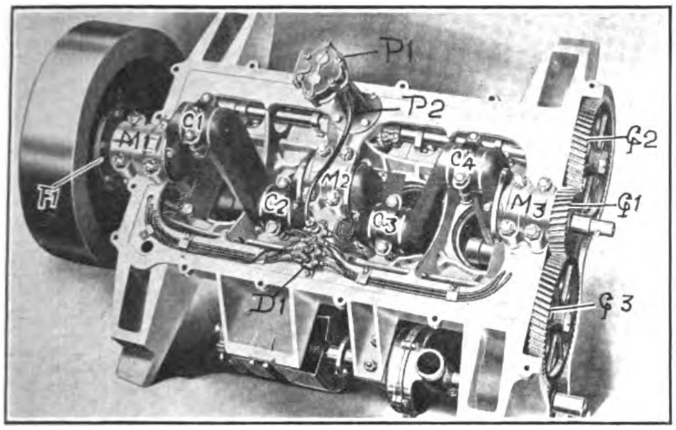

Fig. 3—"Stoddard-Dayton" 1911 construction, showing underside of the motor

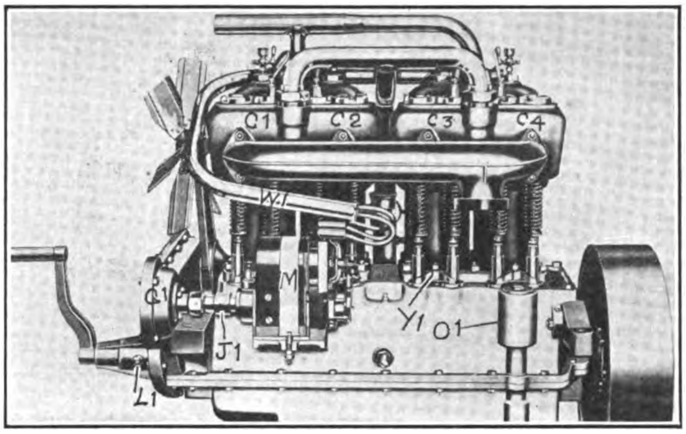

Fig. 4—Motor in the "Stoddard-30" models, showing magneto side of same

Reckoned by the A. L. A. M. formula, the motor of the Stoddard-Dayton "50" develops 40 horsepower; that of the "40," 36.1; the Stoddard "30," 27.2, and the "20," 25.6. The 2½-ton truck has a 27.2 horsepower motor and the 1-ton and the delivery wagon each 25.6. The three commercial models are chain-driven.

†Or dual 34x3½.

Thirty-six inch wheels are standard on all the "50" and "40" models, 34-inch on the "30's" and the 32-inch on the "20's." As to tires, 36 x 5 is listed for the "50" Limousines and Landaulet, 36 x 4½ for the remainder in that class with the exception of the Speedster, which is equipped with 36 x 4—the standard equipment also of the "40" models. All of the "30" class have 34 x 4 tires but the Roadster, which is fitted with 34 x 3½. The "20" equipment is 32 x 3½ throughout. The big truck has 34 x 4 front and dual 34 x 3½ rear. The 1-ton truck 32 x 4 and the delivery wagon 33 x 4.

With no less than 29 models listed for 1911 the Stoddard-Dayton output would seem to be one of the most comprehensive and all-embracing of any of the more prominent American factories. There are four separate chassis designs—Stoddard-Dayton "50" and "40," Stoddard "30" and "20"—besides the commercial models. The "50" class includes the Limousines (the usual style, besides one with four doors). Landaulet, Touring Car (two- or four-door) and Torpedo—all with 130-inch wheelbase; Semi-Torpedo, five-passenger, four-passenger and Roadster—all with 120-inch wheelbase; and the Speedster, with 106-inch wheelbase. Included among the "40's" are two Touring models (one with doors front and rear), five-passenger, four-passenger, Torpedo, Semi-Torpedo and Roadster—all with a wheelbase of 120 inches. The Stoddard "30" class is made up of Limousine, Landaulet, Coupé, two Touring Cars (one with doors front and rear) and a Roadster—all 120-inch wheelbase. The trio of "20's" is made up of Roadster, Touring-Roadster and Touring Car—all 112-inch wheelbase. In the commercial division the 2 1-2-ton truck and the delivery wagon are mounted upon 112-inch wheelbase chassis, while the 1-ton truck has a wheelbase of 100 inches. The tread of all the models is uniformly 56 inches.

The French type of rear wheels are used on the "50's" and "40's," both of which, with the "30" models, are equipped with Universal S. D. demountable rims, with an extra rim.

The spring equipment is semi-elliptic front and three-quarter elliptic rear, being much heavier than the 1910 practice, and with less arch in the design. Shock absorbers are standard on all "50" models. In the matter of equipment, robe rail, foot rest, five lamps, Prest-O-Lite tank, horn, jack, tools, etc., are standard, with dome lights, speaking tubes and similar conveniences on the limousines in the various models. Folding rear seats are fitted in some of the Roadster designs at a small extra price.

Some Details from a Mechanical Point of View

The four 1911 power plants range from the 4 x 4 1-2 inches bore and stroke, which is used in the "20's" and the delivery wagon, and is rated by the company at 25.6 horsepower, to the 50-horsepower motor, which is 5 x 5 1-2 inches bore and stroke. The small motor is of the *bloc* type and is especially designed to serve in freight automobile work, it being used in a 1-ton truck as well as in delivery work. The next size of motor is 4 1-8 x 5 1-4-inch bore and stroke, respectively, and is used in the 2 1-2-ton truck, as well as in passenger automobiles. This motor is rated 27.2 horsepower, and serves in the Model 30, representing a complete line of cars as limousine, landau, coupé, touring car, fore-door car, and roadster. The other motors are 4 3-4 x 5 inches and 5 x 5 1-2 inches bore and stroke—Models "40" and "50" respectively.

The scheme of design of two of the types of motors is shown in the illustrations Figs. 1, 2, 3, and 4, excepting the *bloc* type of motor, which is not illustrated. Remembering that past practice in the Stoddard-Dayton plant was along lines involving overhead valve construction, it remains to be seen that for 1911 the clientèle of the company may take its choice. The overhead construction is retained, as shown in Figs. 1 and 2, but the direct-lift construction is added, as shown in Fig. 4.

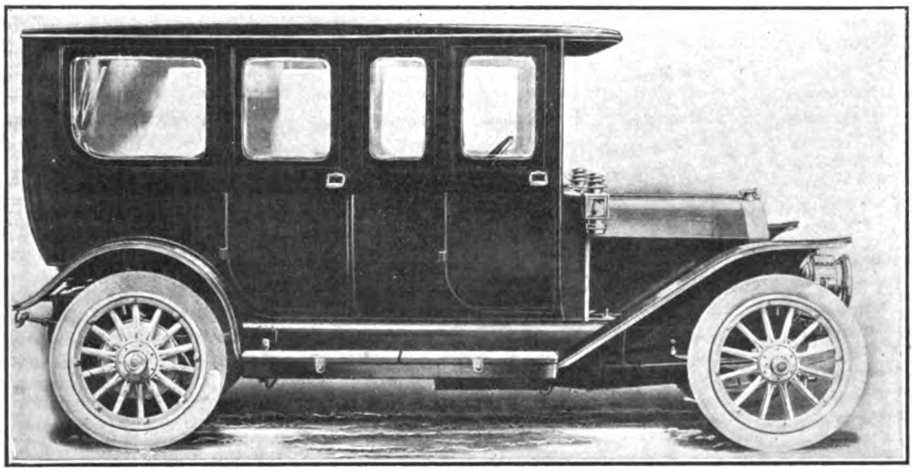

Fig. 6—"Stoddard-Dayton 50" 11-F limousine for seven passengers

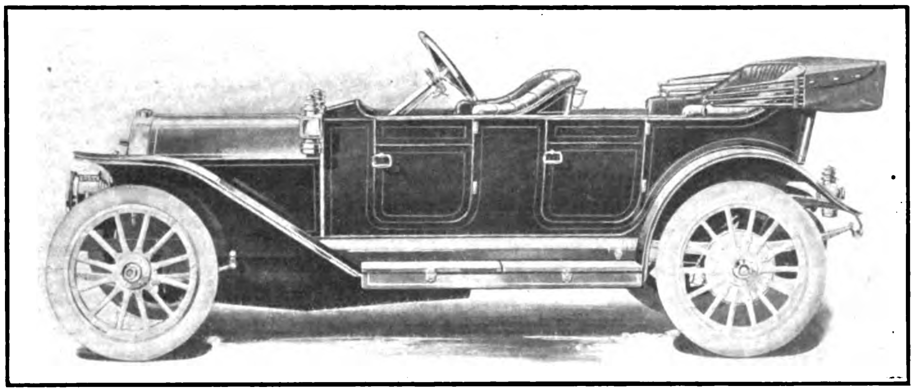

Fig. 7—"Stoddard-Dayton 40" 11-A fore-door touring car for five passengers

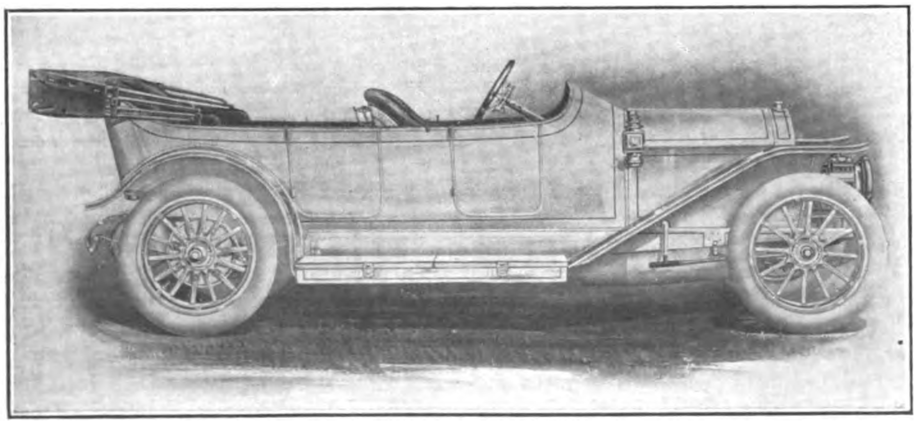

Fig. 8—"Stoddard-Dayton 50" 11-K torpedo for four passengers

As a further indication of a standardized practice, lubrication is worked out to the same completeness in each of the types of motors, using a pump for circulation. Likewise, the cone type of clutch is used in all the models, and the transmission gear is selective and three-speed in all the models, located on the frame in each case, and shaft-drive prevails throughout, excepting in the commercials, which have a side-chain drive. The tread is 56 inches in every case, and the side bars of the chassis frame are pressed steel of the channel section, excepting in the 2 1-2-ton truck. The wheelbase is long in all the models, being 112 inches in the delivery wagon, 100 inches in the 1-ton truck; the shortest wheelbase in the passenger automobile class is 112 inches in Model 20, 11-M, and the longest wheelbase is 130 inches, which obtains in five designs of the Model 50 cars.

The bearing situation is carried out along uniform lines with three plain bearings on the crankshaft in every case, and roller bearings in the transmissions and axles in all the models. It is a notable fact that the tires used on the wheels are selected with a discriminating eye, and with the understanding that but one extra casing will have to be provided in service, since but one size of tire is used in common for the front and rear wheels, and this perfectly uniform situation obtains in all the models.

The left-hand side of the motor is depicted in Fig. 1 with the magneto M1 located on a shelf that is cast integral with the upper half of the crankcase. The water pump P1 is driven from the same shaft, with a silent Oldham type of universal joint J1 between the pump and the gear on the end of the shaft, the latter meshing with the half-time gear in the housing H1. The fan in front is of good design and is driven by means of a belt B1, which is wide and is guided on the large pulley which is placed on the same shaft that furnishes rotation and power to the pump and magneto. The overhead valves show very clearly in this view, the rocker arms R1, R2, R3 and R4 being above and the push rods pass down clearing the cylinders by a proper margin and pass into the crankcase through proper guides to the point of engagement of the camshaft.

The right-hand side of the motor, as shown in Fig. 2, presents the contour of the motor case and the Stromberg carbureter C1, the same being of the multiple-jet type, with glass float bowl, and is flanged to a suitably designed manifold M1, to which is added a shutter A1 for use in adjusting the admixture of atmospheric air as the occasion demands; this shutter is adjusted once for all when the motor is being tuned up.

Fig. 3 shows the motor turned up and the lower half of the crankcase removed. The method of lubrication is clearly depicted here; the pump P1 is fastened to the upper half, and the main supply of lubricating oil passes from the pump through the pipe P2, thence to the distributor D1 and from there to the separate pipes that lead to the bearings to be lubricated. The main bearings M1, M2 and M3 are of large projected area, scraped in, and the nuts that are screwed up on the studs are castellated and a cotter pin is used in each one of them to prevent the nuts from backing off.

The connecting-rod bearings C1, C2, C3 and C4 are liberally proportioned, properly fastened, and the "brasses" are white metal. The half-time gears G1 (the pinion), G2 and G3 are of the herring-bone design, accurately cut and securely fastened to the shafts. The crankshaft is provided with a flange F1 for the flywheel; the workmanship at this point is most exacting.

Perhaps the most notable motor feature of this year from the point of view of this make of automobile lies in the design of the "30" type of motor as shown in Fig. 4. The cylinders C1 and C2 are one of the pairs, C3 and C4 are the remaining pair, they being cast in pairs. The valves instead of being in the head arranged for overhead actuation are in the conventional T-headed way. The magneto M1 is here shown on the left-hand side of the motor, taking its drive without the intervention of a pump by means of a shaft with a universal joint J1, thence to the half-time gear system in the housing G1. The wiring from the magneto is nicely arranged in tubing W1. The starting crank is contrived with a means for holding it in the up position when the automobile is on the road; no strap or other external means being necessary. The lock L1 shows at the side.

Considered from the price standpoint, the long line of the Dayton Motor Car Company offers a wide margin of choice. Beginning with the Stoddard-Dayton "50" model, the fore-door Limousine tops the list at $4,200; Limousine and Landaulet, $4,000 each; Touring Car and Torpedo, $3,000 each; Semi-Torpedo, $2,925; five-passenger and four-passenger cars $2,900 each; Roadster, $2,850, and Speedster, $2,800. The "40" models begin with the fore-door Touring Car at $2,400 and follow on with the Torpedo at $2,350; the regular touring car and five- and four-passenger cars at $2,300 each; the Semi-Torpedo at $2,275, and the Roadster at $2,200. The Limousine and Landaulet in the Stoddard "30" class are listed at $2,700 each; the Coupé at $2,350; fore-door Touring Car, $1,750; regular Touring Car, $1,700, and Roadster, $1,550. The "20" Touring Car is listed at $1,275; the Touring-Roadster at $1,250, and the Roadster at $1,175. In the commercial class the 2½-ton truck is catalogued at $3,000; the 1-ton truck at $1,750, and the delivery wagon at $1,350.

The Hazard Motor

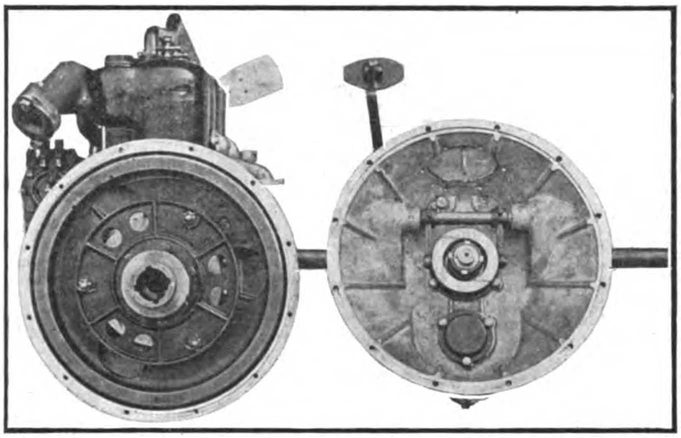

Fig. 1—Looking at the motor with the transmission gear removed, showing the housing in the flywheel

MAKERS of automobiles, especially those who confine their efforts to the relatively light but powerful cars at popular prices, are compelled to face a serious situation involving the question of quality, considering price, and they find that the solution of the problem lies in calling upon specialists for the units required, and it is this condition that serves as the underlying foundation for the success of the specialists who confine themselves to certain classes of work. The Hazard Motor Manufacturing Company at Rochester, N. Y., has taken for its specialty the manufacture of power plants, and experience has taught the company to limit its undertakings to the quantity production of a type of power plant that will be sufficiently good to carry its name and trade-mark out into the world and be a fair representative of that measure of quality that perpetuates an honest effort.

The illustrations as here presented are of the unit power plant as it has been refined and brought up to date, the principal dimensions of which are as follows:

DIMENSIONS AND SPECIFICATIONS OF 24-HORSEPOWER MOTOR

Number of cylinders, 4;
Bore of cylinders, 3 3-4 inches;
Stroke, 4 1-2 inches;
Piston pin bearings, 1 x 2 5-16 inches.

DIMENSIONS AND SPECIFICATIONS OF 30-HORSEPOWER MOTOR

Number of cylinders, 4;
Bore of cylinders, 4 inches;
Stroke, 4 1-2 inches;
Piston pin bearings, 1 x 2 1-2 inches;
Crankpin bearings, 1 1-2 x 2 1-4 inches;
Front crankshaft bearing, 1 1-2 x 2 3-4 inches:
Center crankshaft bearing, 1 1-2 x 2 1-2 inches;
Rear crankshaft bearing, 1 5-8 x 3 1-2 inches;
Camshaft diameter, 7-8 inches;
Flywheel diameter, 16 inches;
Diameter of front support, 2 1-2 inches;
Diameter of rear support, 1 1-2 inches;
Drop from center of rear support to crankshaft center, 3 inches;
Off-set of cylinders, 3-8 inch.
Outlet of water manifold, 1 1-4 inches (diameter of holes):
Outlet of exhaust manifold, 2 inches (diameter of steel tubing);
Weight of power plant unit, 450 pounds (without magneto).

Underlying Principle of the Design

The unit power plant with its three-point suspension has for its basis the fundamental idea that the spiraling of the chassis in response to road inequalities shall not be transmitted to the mechanism constituting the rotative members in the power plant. It is a principle in design that external disturbances cannot be transmitted through the shell of a power plant if the same is suspended at three points. It is a recognized fact in machinery designing that bearings must be in strict alignment, if bearing trouble is to be aborted. It is known that deflection is a property in every structural member that is subjected to strain, and the amount of the deflection is the only thing that can be limited by taking proper measures. Men frequently say a large beam, for illustration, when subjected to a light load does not deflect, but it does. When an elephant wants to cross a river he is not averse to using a bridge if he thinks the same is strong enough to carry his weight; how does the elephant determine to his satisfaction as to the strength of the bridge? Does he not strike a blow and observe if there is a quiver, in other words a deflection, or a series of deflections? Relative to the size of a bridge, an elephant is quite small; nevertheless, there is an appreciable deflection, and the elephant being accustomed to gauging such matters, uses his instruments of precision to the best advantage.

The most advanced designers being fully alive to the laws which govern deflections and distortions in members, instead of trying to avoid the inevitable, take advantage of "closed couples" and such other attending functions as will afford to them immunity from interference.

In the unit power plant design all the bearings are brought into correct alignment by the simple expedient of using a single boring bar of great rigidity with a plurality of cutters working simultaneously, resulting in the accurate centreing of all the bearings to a common axis. The crankshaft, as shown in Fig. 4. is first rough-machined and thereafter ground on centers so that it, too, is not only round but the main bearings rotate on a common axis. When the crankshaft is erected into place and is supported by a cylindrical structure, as in the Hazard motor case, it follows that there can be no outside interference because the spiraling of the chassis frame cannot be transmitted through the motor case, nor will there be disagreement within since the main bearings are bored to a common axis and the crankshaft is ground on common centers.

Among the remaining considerations that have to do with the maintenance of correct alignment is the rigidity of the crank-

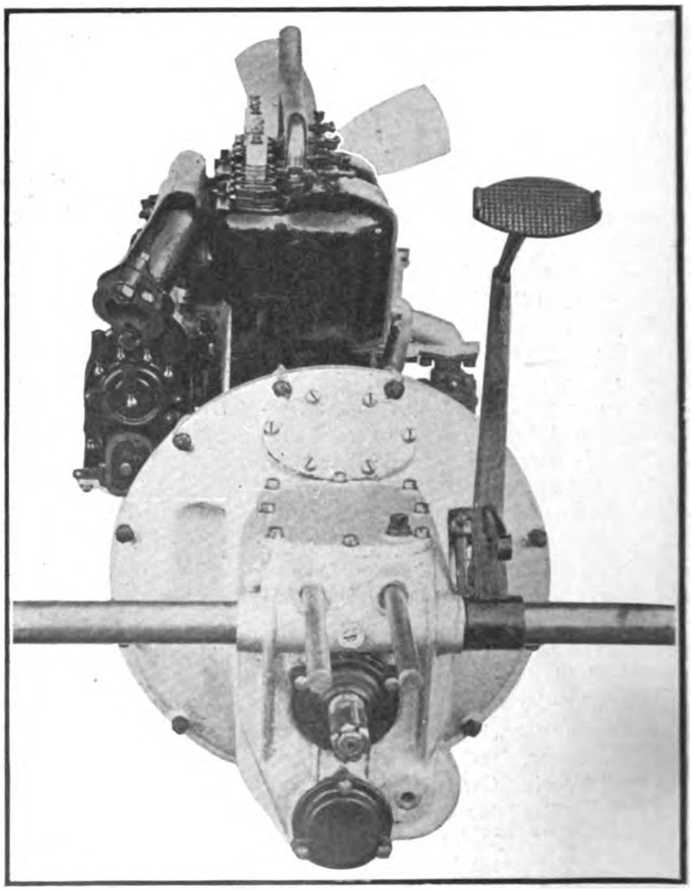

Fig. 2—Looking at the motor from the rear with the transmission gear in place and a brake pedal at the right

PRESENTING THE HAZARD POWER PLANT IN SUFFICIENT DETAIL TO BRING OUT THE FINE POINTS IN DESIGN AND CONSTRUCTION

shaft, for, as will be understood, if the crankshaft is lacking in its ability to interpret the torquing increments, it will be subjected to bending, torsional and shearing moments. The bending moments will have the effect of peening the main bearings, thus making them larger in diameter at the extremities than they will be at the intermediate position, resulting in disaster, however, since the bearing pressure will increase enormously toward the center, and in accordance with the performance with bearing metal, the lubricating oil will refuse to spread over the hot surfaces and the condition of so-called "freezing" will step in. The torsional moment if it is not sufficiently resisted will alter the axlewise length of the shaft just as the length of a rope is made long or short by putting twists into it. The shearing moment is not a matter of serious purport.

As the specifications indicate, the cylinders are offset, it being the aim of the company to make the amount of this offset just enough to compensate for inequalities of piston pressure as they obtain when the cylinders are not offset. This compensating factor affords the advantage of reducing the friction component, hence the total of the fixed losses in the motor, but there is another point that is rarely taken into account. Crankshafts deflect because they are subjected to pressure, and they give out when they are put in a position to resist rapidly varying loads. Offsetting the cylinders is of more advantage from the point of view of reducing the load variation than from the other angle.

Despite the excellent care with which the design has been consummated with a view to reducing the responsibilities of the various members, notably the crankshaft, it is the practice in the production of this motor to use the grades of steel that are known to hold kinetic properties, and the method of manufacture, including the process of heat-treating, is with the expectation that the desirable properties are accentuated to the greatest possible extent without reaching into other zones of danger. The shape of the crankshaft and the proportions of the throws are in line with the general endeavor, with the added advantage that quantity production does not lead to diminished quality. In the several other respects the plan of design lends facility to the employment of jigs, special tools and fixtures, all of which add to the rapidity with which the work can be done, to the exclusion of the personal equation, leaving to the artisans but a single choice.

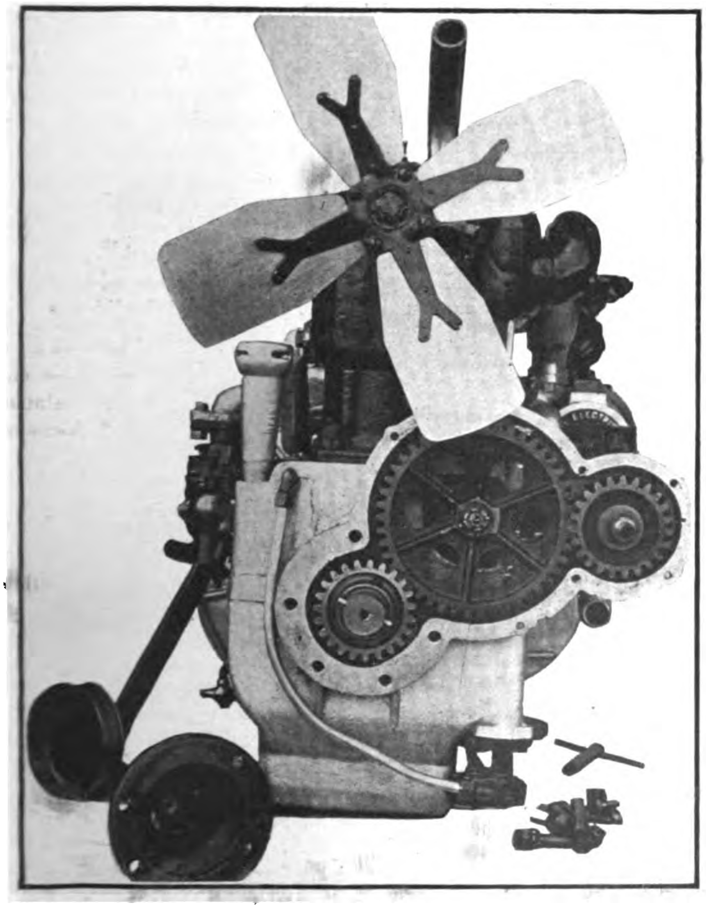

Fig. 3—Looking at the front of the motor, showing the half-time gear housing with the cover off, air propeller and other details

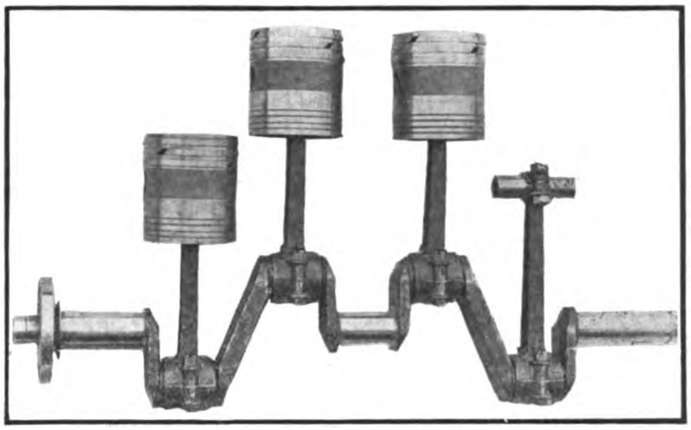

Fig. 4—The crankshaft with the connecting rods and pistons in place, showing a flanging for the flywheel and other refinements

The clutch end of the motor is shown in Fig. 1, it being unbolted at the flywheel housing, thus exposing the flywheel at the left and the clutch mechanism at the right, showing the telescoping shaft and the driving keys. Fig. 2 is a perspective of the motor from an elevated position presenting the same when the two halves of the case are bolted together, showing in the foreground the rear end of the crankcase. The clutch is of the multiple disc type, but instead of being run dry or under fixed conditions of lubrication, a provision is made for supplying a stream of lubricating oil, the same being filtered and used throughout a myriad of cycles.

The transmission gear in its compact housing as shown in Fig. 2 has three forward speeds and reverse, with a selective means of manipulation and a straight line control. The pedal for the clutch is presented in Fig. 2 at the right of the case and is of the extension type. Instead of casting arms integral with the case, and using them to suspend the power plant in the chassis frame, means are afforded for the utilization of drawn-steel tubing, the sizes of which are given in the specifications. The tubing is passed through finished holes, one of which is shown in Fig. 2, and it is found in practice that this method of suspension is both substantial and light.

Referring to Fig. 3 of the front end of the motor, the cover of the half-time gear housing is removed showing the pinion on the crankshaft meshing with the half-time gear on the camshaft, and at the right-hand side the pinion that drives the magneto is also in mesh in the train. When the cover is fastened into place the half-time gear housing is grease-tight, and accuracy of the gears together with the proper centering of the shafts, including adequate means of lubrication, results in noiseless performance. The magneto is placed on the right side of the motor as shown in Fig. 3, but the carbureter is on the opposite side, it being the idea of the designer that the greatest measure for safety lies in separating the fuel system from the ignition system in this way.

One of the main points, and the particular one that cannot be illustrated, lies in the use of selected materials in the construction of the motors, and by means of a well-contrived set of special tools the power plants are turned out in quantity, at a reasonable price, but with such accuracy that they come up to an exacting demand.

Aeroplane Traffic

BY MARIUS C. KRARUP. A REASONED COMPARISON BETWEEN AEROPLANES, MOTOR BOATS, BICYCLES, MOTOR BICYCLES AND AUTOMOBILES, WITH REGARD TO THE CHANCES FOR THE IMMEDIATE GROWTH OF AN AEROPLANE INDUSTRY

AEROPLANE traffic shall be, though Mother Shipton forgot to say so. All are interested in forming and coloring a mental picture of what it will be in five years. Few doubt that it will profoundly affect human life and civilization, sooner or later. The terrors of war will be so abhorrent, many believe, that wars will cease. The cost of collecting import duties on light and valuable merchandise, already exorbitant, will rise to an impossible height, compelling free trade between nations. The values of residence property will undergo a transformation in which aeroplane traffic will be a factor scarcely less important than the railway and the automobile. About these things all may dream. But civilization in general is a complicated structure, and none may be very sure how things will turn out. Otherwise with regard to those features in aeroplane evolution which depend on physical laws and those fundamental human instincts which never change—self-preservation, love of new sights and sensations, desire for control of natural forces, desire for a sense of power with relation to other humans.

The mechanical laws governing aeroplane flight have already been revealed sufficiently to permit a glimpse of the immediate future, a reasoned glimpse. At the present moment suitable design already accounts for ninety per cent., more or less, of the flying qualities of any aeroplane machine, and what may be added to these qualities by putting more money in materials and workmanship counts for correspondingly little. With a very good propeller a ten horsepower motor weighing 150 pounds or more and obtainable in the open market for $150 is likely to do better work in an aeroplane for one or two than that which any of the special aviation motors of higher power and smaller weight can do with a propeller of only ordinary efficiency. The Wright brothers have practically shown this to be true. Louis Bréguet, only the other day, proved still more. Santos-Dumont, by placing his Demoiselle type in the market at a price of $250, without the motor, has shown that good workmanship and materials are not necessarily very costly, and improvement of his design would not change this fact, so long as the question is only of producing aeroplanes with fixed wings and rudder control of the types so far used in practice. These will continue to be very attractive and may undoubtedly be improved in many little ways without increase of their intrinsic cost. As soon as it is generally realized that a little ten horse-power aeroplane which will fly quite well in fair weather may be produced for the price of a little motor boat (whose usefulness and pleasures are also limited to fair weather), the popular demand for such aeroplanes will of course assume enormous proportions. Unless the monopoly of patent rights interferes seriously, motor and propeller equipments will be sold over the counter and farmer boys will make their own structures after patterns obtained from correspondence schools or from enterprising firms exploiting the situation. Of course there will be accidents, many of them, but there will also be a development of a keen sense for weather and weather indications in wide circles, and there will be thousands of brains working overtime to devise improvements in the machines and in the means for ascertaining the meteorological conditions near the earth and in the higher altitudes. As only small size renders cheap construction compatible with strength, all the emphasis is on the small dimensions of these machines and, when the general design is otherwise suitable, on those features which specially contribute to render small dimensions sufficient for support. Aside from a reliable motor, these are mainly safe and efficient planes, a really efficient propeller and reduced air resistances. Since Bréguet publicly demonstrated the superior qualities of resilient propellers—a superiority dependent upon correctness in details and a certain correspondence between the propeller action and the speed and torque of the motor—nearly all that is required to give birth to a popular sport which will take possession of the young male population in a degree never witnessed since the halcyon days of the bicycle, is the crystallization into one design of the best features now found in many. The value of flexible elements in the planes has already been demonstrated in two important flights, and planes curved "in series" seem to constitute the only required feature which has not yet been publicly exhibited. There will then appear a monoplane with a 14 to 16-foot span, for one person; a biplane with a 16 to 20-foot span, for two or three persons. Having fixed wings and rudder control, these machines will not be safe in puffy weather, but they will be very attractive and safe enough for a good combination of sporting blood and prudence.

The first glimpse into the future seems to reveal a few hundred thousands of these little flight machines used by the young and hardy for sport and pleasure, for interurban visits, for excursions to sea and mountain, for the exploring of hunting grounds and natural fastnesses not too far removed from the arteries of civilization and the depots of supplies. Low cost as an incentive in the heat of a spectacular aviation movement, world-wide and intense, must find this practical interpretation. And the motor to be used is likely to be one in which the flexibility of the automobile motor will be sacrificed in favor of high reliability at a constant power development, combined with lower price. In other words, the popular motor for little aeroplanes may be a lightweight of the same pattern as that to which the owner of small commercial trucks is looking forward or like the small high-speed motor for boats not yet quite realized rather than that of the automobile racing car. A clutch will permit a start without assistance and a landing without necessarily shutting off the power, while the gliding qualities will be substantially improved by a propeller whose blades are on edge when not in use.

To estimate the probability of an immense popularity for small aeroplanes of the kind referred to, it is only necessary to compare the factors for and against them with the value of the same factors for and against the motor boat, for and against the bicycle, for and against the motor bicycle, and finally for and against the automobile. The favorable factors may be multiplied above the division line, the unfavorable factors below, when an estimated numerical value is given to each, and the quotient obtained in each case will show, after a fashion, the relative claims upon popularity of each of the five modes of locomotion.

The factors considered above the line may be:

A, representing the population of the territory where each form of locomotion may be practicable and from which it may therefore draw its support.

N, representing novelty.

S, representing speed.

R, representing carrying capacity.

E, representing esthetic satisfaction and sport and

F, representing freedom of movement in getting from one place to any other, in which factor weather and actual road conditions are included.

The factors below the line may be

C, representing cost of purchase or production.

D, representing danger.

L, representing chances of delay, principally those due to troubles with the mechanism and perhaps caused by salt water or bad roads.

I, representing bother and incumbrance in stabling or disposing of the machine when it is not in use.

U, representing dirt, dust and caretaking and

X, representing manufacturing difficulties in producing or delivering a machine of the design and qualities required for realizing the numerical values assumed for the properties denoted by the other letters of reference.

The maximum numerical value used is 10, but for the aeroplane machine this has been doubled for I in consideration of the extraordinary difficulties which, at least for the present, the inhabitants of cities will experience in stabling aeroplane machines. On the other hand, in the case of the automobile, it seems that it might be proper to multiply the final figure by 5 in recognition of the fact that the automobile to a very large extent takes the place of a recognized and long-established utility.

While the figures used are necessarily not above criticism and others may be substituted by readers whose estimate varies from that of the writer, and while it may be subject to dispute whether multiplication and division truly represent the relations which exist between these figures and the effect of the various properties upon "commercial popularity," or the number of machines of each kind to be demanded by the population of this country, the table given herewith should nevertheless supply a foundation upon which any person may build up a rational guess, modified by his own estimate of details, with regard to the probabilities of the immediate future for aeroplanes of the type referred to:

Upper Lower	$\frac{A}{C}$ ×	$\frac{N}{D}$ ×	$\frac{S}{L}$ ×	$\frac{R}{I}$ ×	$\frac{E}{U}$ ×	$\frac{F}{X}$ =	Co-efficient of Public Demand
Aeroplane.......	10 ×	10 ×	10 ×	2 ×	10 ×	5	166
	3 ×	5 ×	2 ×	20 ×	1 ×	x	X
Motor Boat.....	1 ×	2 ×	1 ×	10 ×	5 ×	1	100
	3 ×	2 ×	3 ×	5 ×	2 ×	5	900
Bicycle..........	10 ×	1 ×	3 ×	1 ×	3 ×	5	180
	¼ ×	2 ×	1 ×	1 ×	5 ×	1	
Motor Bicycle...	5 ×	2 ×	5 ×	1 ×	3 ×	1	150
	1 ×	10 ×	5 ×	2 ×	10 ×	2	2000
Automobile......	7 ×	2 ×	5 ×	6 ×	2 ×	3 × 5	126
	10 ×	5 ×	1 ×	6 ×	8 ×	2	48

It may now be inferred from this table that the popularity of the simple aeroplane machine will under all circumstances greatly exceed that of the motor boat and the motor bicycle; that it would rival that of the bicycle, if the chance of getting a satisfactory type of aeroplane manufactured and delivered (expressed in divisor X) were the same as in the case of the bicycle; that it will exceed the popularity of the automobile, if those difficulties in design and manufacture which are expressed by giving X the value of 2 for the automobile, do not run up to more than 62 for the aeroplane; in other words, if the chances for producing an aeroplane whose traveling qualities are somewhat as expressed in the numerical values assigned to it are not absolutely remote or infinitesimal. And if these chances are expressed by the figure 20, which seems a high estimate and one destined to be reduced very rapidly in proportion as the understanding of design requirements becomes public property through the performances of the various types at aviation meets and in long-distance contests, the inference from the table should be in favor of seeing a number of small aeroplanes in use before long considerably exceeding the number of automobiles and beginning to rival that of bicycles. In similar estimates made in other fields, it has been thought that the true numerical relations were much exaggerated by multiplication and division of the factors respectively for and against the estimated result, and that the square roots of the figures representing the "coefficient of public demand" would more nearly represent reasonable expectations. On this basis, and with the value of 20 for X in the case of aeroplanes, the intrinsic public demand for small aeroplanes, bicycles and automobiles would then be represented in the square roots of 8.6, 180 and 2.63, which are 2.8, 13.4 and 1.6, and an expansion of aeroplane manufacture aiming for a production of aeroplanes on this scale should be justifiable. But in all of this one rather important fact has been left out of consideration. It relates to the much smaller than average purchasing capacity which is characteristic of that class in the population who would buy aeroplane machines in which the safety has not been worked out more fully in the very construction of the machine than is here supposed to be the case. The small and cheap aeroplanes are still subject to mortal dangers from wrong estimates of the weather and from occasional motor troubles. Some allowance greater than that involved in the figures given under C for cost and under D for danger, should probably be made for the immediate present, say for two years out of the five next years which constitute the period for which this estimate is worked out, but in practice, and for the period as a whole, it would seem reasonable to hold this consideration to be offset by two others which are favorable, one being the unavoidable progress in design on lines which may not now be foreseen and the other demand for larger and costlier but also almost perfectly safe aeroplanes—as safety in traffic is rated in other forms of locomotion—by which diversity and volume will be added to the aeroplane industry, giving another outlet for manufacturing facilities. Whether the popular demand will swing a little more to the cheap, individual aeroplane or a little more to the aeroplane omnibus and excursion vehicle seems to be a subordinate question which need not be answered till it answers itself, while the fact that a public demand for aeroplanes in general may be reasonably estimated as likely to outgrow in five years—giving the necessary time for development—the present demand for automobiles in the proportion of 2.8 to 1.6 and to approach the demand for bicycles in the proportion of 2.8 to 13.4, in conjunction with the supplementary fact that this estimate can be based almost solely upon what has already been accomplished in aeroplane design and manufacture, seems to be sufficiently remarkable to stimulate investigation of the manufacturing opportunities which have been opened to the world mainly through the practical work of the Wright brothers, though the name of Blériot should not be left unmentioned, and which seem at present to be mainly appreciated, in an industrial sense, in France.

There remains to be indicated the probable development of the complete individual aeroplane built on industrial lines and of substantial materials, costly as an automobile in varying degrees according to its equipment, capable of carrying considerable loads at moderate speed and light loads at enormous speed, safe in almost any weather and second in security against failure of the motor power only to the third type which may be foreseen; namely, the multiple aeroplane, much longer than broad, equipped with a series of motors working by releasable clutches on one or two propeller shafts carrying a series of propellers, controlled mainly through its rows of adjustable wings and intended as a public conveyance or an instrument of war.

(*To be continued.*)

Mountain Work Hard on Brakes and Motors

The advantage of kinetic brakes, so called, rather than to depend upon the friction of the members of the brakes proper is not given the attention that the plan deserves. The average autoist is skeptical, that is to say, he is inclined to the belief that it will damage the motor to use it as a retarding machine. Certainly, if the motor is capable of propelling an automobile up hill it should be able to retard the same weight down hill. If a car goes up hill at the rate of 20 miles per hour the motor must do a certain amount of work and in going down the same hill at the same speed, if it is to serve in the capacity of a kinetic braking system, it will be required to do exactly the same amount of work as is represented by the propelling of the car up the hill.

When the brakes (proper) are used, owing to the friction of the members, they wear out. But when the motor is used instead the work comes upon well-lubricated bearings, which last just as long under the work imposed upon them when the car is going down hill, as under other road conditions.

In sharp contrast to many automobile organizations, the Worcester (Mass.) Automobile Club "gets action" on everything it undertakes. It is the progressive spirit behind the club that marks it as something out of the ordinary. It is the same spirit that has pushed the club forward and made its name mean something to motordom.

Formed over ten years ago for the sole purpose of increasing and fostering interest in automobiles and motor car sports, the club after a typical winning struggle stands out to-day as one of the foremost organizations of its kind in the United States.

To the outsider the fame of the club rests to a large extent upon its success in conducting a series of five hill-climbing contests which were amply noticed all over the automobile world. But in a larger sense the club has been of even more potent force in popularizing the automobile in its territory.

When it was born in 1900 there were 15 owners of automobiles in Worcester, and J. M. Bigelow and William J. H. Mourse, two of the pioneer motorists of that city, had considerable difficulty in getting them to affiliate in a club. Mr. Bigelow was chosen first president, when the motorists finally decided to get together and the meetings of the organization were held at his home during the early days. In 1904 Asa Goddard and B. A. Robinson took hold of the organization, raised the membership fee to $5 and secured headquarters at the Bay State House. Mr. Goddard was elected president.

At first the club had a single room in the basement of the hotel, but after two years more adequate quarters were taken on one of the upper floors. As soon as the club issued forth from its chrysalis form it assumed a commanding position in the automobile life of Worcester. In 1905 John P. Coghlin was selected to head the club, which by that time had 40 members and an income of sufficient size to finance its activities in an economical way.

With the advent of Mr. Coghlin the club began to grow rapidly and after he had been in office a year a suite of seven rooms were leased in the Chase building and the club spent $8,000 in fitting them up in comfortable style. The dues were doubled and despite the raise the membership continued to swell until now its rolls contain the names of nearly 1,000 of the prominent and influential men of Worcester and vicinity. The list includes leaders in society, business and professional life, and naturally enough the club has a distinct influence on about everything of importance that is to-day presented to Worcester's consideration.

The work of Mr. Coghlin was of a high order and the club endeavored to persuade him to accept a sixth term as president. He declined, however, and at the last election Daniel F. Gay was chosen to succeed him. Mr. Gay is also an aggressive official and much progress has been made under his administration.

For five years the club has conducted a hill climb on Dead Horse Hill, a straight but very stiff grade. The entry lists have always been typical and some remarkable achievements have been attained in the various events. During the past summer the club promoted a track meet which was thoroughly successful.

And yet with that record to look back upon the club is not a sporting organization in any sense. Neither is it a social or political organization. It has a decalogue which outlines its main objects as follows:

First—In scrutinizing legislation for a square deal for motorists.

Second—In boosting interest in automobile and motor car sports.

Third—In securing good roads both in the city and its suburbs.

Fourth—In the erection of signs indicating directions and speed limits.

Fifth—In controlling speeders and autoist lawbreakers.

Sixth—In promoting sociability among its members.

Seventh—In giving its members and friends the best regardless of cost in the line of clubrooms and comfort.

Eighth—In promoting the club by increasing its membership among autoists.

Ninth—In the registration of chauffeurs and owners, and lastly

In conducting functions, such as club runs, entertainments and the annual outings for the orphans and poor children of the city.

The present quarters of the club include ten rooms and the furnishings and fittings are attractive and comfortable. The cuisine of the club is gaining a wide reputation and its patronage is growing by leaps and bounds.

Frequently high personages in the business and political world have tasted the hospitality of the club and the members never yet have had cause to feel ashamed.

To-day the club is free from debt of all sorts and is in commendable conditions in every way.

The officers are as follows: Daniel F. Gay, president; Chester E. Greene, vice-president; Henry F. Blanchard, secretary, and Milton C. Snyder, treasurer. The board of governors includes the four officers named and Alfred Thomas, M. A. Macker, John W. Harrington, Charles Case, William F. Whipple and R. W. S. Negus.

Plans are already afoot for the sixth annual hill climb, which is scheduled to be held in June, 1911.

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL CLIMBS, ETC.

Dec. 1	Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Dec. 31-Jan. 7, '11	New York City, Grand Central Palace, Eleventh Annual International Automobile Show.
Jan 7-14, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Manufacturers.
Jan. 16-21, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4,'11	Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories, Exclusively.
Feb. 6-Feb. 11,'11	Chicago Coliseum, Tenth National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.
Mch. 4-11, 1911	Boston, Mechanics' Building, Ninth Annual Show, Licensed Automobile Dealers' Association.

Races, Hill-Climbs, Etc.

Sept. 16	Algonquin, Ill., Annual Hill Climb of Chicago Motor Club.
Sept. 17	Syracuse, N.Y., Track Meet of Automobile Club of Syracuse, Syracuse Automobile Dealers' Association and the New York State Fair Association.
Sept. 20-22	Louisville, Ky., Reliability Run, Auto Club, Louisville.
Sept. 24	Belmont Track, Narbeth Race Meet, Norristown Automobile Club.
Sept. 28-30	St. Louis, Mo., Third Annual National Good Roads Convention.
Oct. 1	Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley and Massapequa Sweepstakes.
Oct. 3	Louisville, Ky., Reliability Run, Louisville Automobile Club.
Oct. 6-8	Santa Anna, Cal., Track Meet.
Oct. 7-8	Los Angeles, Cal., Speedway Meet.
Oct. 8	Philadelphia, Fairmount Park Race, Quaker City Motor Club.
Oct. 14-18	Washington, D. C., Start of Washington Post Reliability Run to Richmond, Va.
Oct. 15	Long Island Motor Parkway, Grand Prize, Automobile Club of America.
Oct. 15-18	Chicago, Ill., Chicago Motor Club's 1,000-Mile Reliability Run.
Oct. 27-29	Dallas, Tex., Track Meet.
Nov. 3-5	Atlanta, Ga., Speedway Meet, Atlanta A. A.
Nov. 5-6	New Orleans, La., Track Meet.
Nov. 6-9-13	San Antonio, Tex., Track Meet.
Nov. 24	Redlands, Cal., Hill Climb.
Nov. 24	Savannah, Ga., Road Race, Savannah Automobile Club.

Foreign Shows and Races

May 1-Oct. 1	Vienna, Austria-Hungary Automobile and Aviation Exposition.
Aug. 1-Sept. 15	French Industrial Vehicle Trials.
Oct. 15-Nov. 2	Paris, France, Aeronautical Society Show.

THE AUTOMOBILE

Vol. XXIII Thursday, September 15, 1910 No. 11

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

REFINEMENTS are made from season to season as the finger of necessity points the way, but it cannot be said that necessity is the servant of the user of the automobile in every case.

* * *

NECESSITY may be the servant of the maker, rather than of the user, in which event it stands to reason that direct benefit will accrue to the maker rather than to the user.

* * *

BUT this situation, while it has its misfortunes, is not good ground for contending that the advances that are indicated by real experience should not be indulged in.

* * *

WHEN a maker puts forth his initial effort and he finds by after experience that some of the details of design and construction are lacking in stamina, what remains but to make the necessary corrections at the earliest possible moment?

* * *

WHAT are necessary corrections? Is it necessary to correct all the automobiles that were previously placed in the hands of the users, as well as to eliminate the faults thus discovered, this being the reason for making changes?

LEGALLY, no. Morally, perhaps. Wisdomly, yes. Why, for a round dozen of reasons. What are some of the reasons for claiming that faults should be corrected in the cars that are sold and paid for?

* * *

PRIMARILY, if the money paid in for a car is not counterfeit, the car should not be counterfeit. The law of fair dealing demands that an equivalent shall be extended to the purchaser.

* * *

EXPEDIENCY, business acumen, and the precedents that accompany ultimate success, all point the way to the correction of error by the one who errs.

* * *

WHAT is the reward of merit? Success, lasting success. What is the price of infamy? Degradation, downfall, oblivion. Merit is best defined in the process of making good. If a device is not what it should be, what a splendid advertising medium will the purchaser become if he is treated like a white man!

* * *

ADVERTISING—what is advertising? Is it horn-tooting? Would it avail a burglar anything to toot his horn? Imagine a two-color insert with 72-point bold-face type proclaiming: "I am a burglar; my skill is known to even the Bank of England"!

* * *

BUT a satisfied client; a man who, in good faith, pays down good, honest money; takes title to an automobile, and, after running it a week, finds that (a) the rear wheels will not stay on, (b) the clutch will not hold, (c) that the motor is so defective that it is worthless for the purpose; supposing the maker should say to this man: "Come, let us treat you fairly; here is a good automobile to replace the bad one that we delivered to you for your good money." The result?

* * *

FIRST, the maker, feeling absolutely honest, becomes strong. Then, the bank, realizing that the maker is strong, leaves the "latch-string" out. Again, the men who work for the maker, knowing that he is a fair man, do twice as much work, and better work, every working day. But the user, what of him?

* * *

JUST think of it: The user, the man who was treated fairly; the customer who, after getting a defective car, was advised that it would be exchanged for a car that would measure up to the promise of the maker—remember, just up to the promise of the maker; no more.

* * *

IS it too good to be true? In some instances, perhaps; in other cases, no. One of the now most successful makers of automobiles on the American market replaced every automobile it made during one year. Did the company go broke, so to speak? No. It made just so many four-page, two-color inserts in a paper that has a circulation of 90,000,000, that goes to press every day in the year—the company advertised and it won out.

Premier Injunction Denied

SUPREME COURT JUSTICE PUTNAM DISSOLVES TEMPORARY ORDER RESTRAINING DELIVERY OF GLIDDEN TROPHY TO CHALMERS COMPANY

ON the ground that the Court would not assume jurisdiction to overset the ruling of a duly constituted sport-governing body in the absence of fraud alleged and shown, Justice Putnam, of the Supreme Court of New York, has dissolved the temporary injunction applied for by H. O. Smith, president of the Premier Motor Manufacturing Company, to prevent the Contest Board from turning over the Glidden Trophy to the Chalmers Motor Company.

The opinion of the Court is as follows:

This is a motion to continue the temporary order of July 23d, restraining the delivery of the 1910 Glidden Trophy. The referee. Mr. A. H. Whiting, decided in favor of plaintiff's car. The Contest Board, however, sustained an appeal and awarded the trophy to the Chalmers Motor Company. Plaintiff charges that this action of the Contest Board was unwarranted, being against the Association rules, contrary to the terms and conditions under which the contest took place, and a breach of the trust created by the donor's deed of gift. This suit seeks to set aside the decision of the Contest Board and to reinstate plaintiff as winner.

In 1905, Mr. Charles J. Glidden offered this trophy for yearly competition under the terms of a deed of gift to the American Automobile Association, providing for the adoption of rules to govern such contests. This was to be a reliability run, since called the "Glidden Tour." The deed of gift (as later modified) declared that this trophy should be competed for annually by members of the Association. and that the winner should hold the trophy until won by another. The A. A. A. had adopted various rules through its Contest Board, to which has been delegated the regulation of such competitions. In March, 1910, the Contest Board issued advance copies of a set of rules, called the 1910 Contest Rules, intended to govern the various competitions to be conducted under sanctions issued by that Board on behalf of the Association. These were subdivided to apply to many different contests, including reliability tests.

The purpose of the Glidden Tour is to try out and test the endurance of what manufacturers call a "stock car," that is, a car such as is regularly sold to purchasers, and not one specially equipped for a contest. In the rules for 1910, the entrant was required to file a stock car certificate of description, in which the details of the car were fully set forth. A technical committee was to make a preliminary inspection of the stock car to determine if it corresponded with the stock car certificate. Various provisions were made as to the examination and report by this technical committee, as well as regulating the penalties in the contest after the cars should have entered upon the tour.

Plaintiff was the entrant in the 1910 contest of a Premier car. In the certificate of description was mentioned a hand oil pump and oil tank. This car was duly examined by the technical committee and declared to be eligible. During the tour a protest was made, upon the claim that this hand-pump to inject oil into the crankcase of the engine of the Premier car was not a part of the regular stock equipment. At the conclusion of the tour, in which plaintiff's car showed the best score, this protest was considered by the referee, who deferred action until he had received a special report from one of the technical committee who had visited the factory of the Premier Motor Manufacturing Company. Subsequently, the referee overruled the protest and declared plaintiff's car the winner. The Chalmers Motor Company, who had entered a car in the name of the defendant, George W. Dunham, appealed from this decision to the Contest Board. which. after notification to the plaintiff, took up the appeal on July 21st, and after receiving proofs by affidavit and hearing arguments, on July 22d, sustained the appeal of the Chalmers Motor Company, on the ground that there was no sufficient evidence to prove that the auxiliary oil tank and pump equipment was stock equipment. so that the Premier Company had failed to furnish evidence sufficient to establish the stock status of its cars entered in respect to this lubricating equipment, and for that reason the Premier cars were disqualified.

It is a primary principle of all sporting contests that rules must be made by the bodies conducting them, and that those regularly appointed must decide who wins. The entrants in such competition, as a matter of fairness, agree to abide by the decisions of the umpires, referees. or boards having jurisdiction, as the rules may provide. Especially is this true in a contest where the points of eligibility are highly technical, and the Association is composed of experts who themselves are well fitted to judge. Before a dissatisfied entrant can ask the courts to interfere and set aside the rulings of a sport-governing body there must ordinarily be evidence of fraud, either by a competitor, or by the official making the decision. The track judges, umpires, referees, executive committees. and governing boards of such associations are supreme within themselves when acting under their recognized authority. If they give the parties concerned a fair opportunity to be heard, and there is evidence on which their findings can be based, their decisions, in the absence of fraud. are not subject to judicial review. Thus, Judge Gildersleeve, delivering an opinion reversing a special term order which granted an injunction in favor of a disqualified contestant at a race track, said:

> "When the original contract was entered into, * * * , the owner of the said colt, in effect, subscribed to the defendant's rules, and they are binding upon his successor. Those rules named the tribunal to which any dispute. that might arise out of the contract, should be submitted. That tribunal was the executive committee of the defendant corporation. They had jurisdiction of the cause of action alleged in the complaint herein. and it was the duty of the plaintiff to submit to their decision." (Corrigan v. Coney Island Jockey Club, 48 N. Y. St. Rep. 582, 586.)

These principles have been generally recognized. The fact that this trophy is of large value and that, although in the form of a sporting contest, the tour really affords a test of the endurance of a car, from which important financial consequences ensue, does not change the rule. Such consequences flow from many modern sporting contests, but these results do not give the court jurisdiction.

The rule that courts of equity will interfere to secure the possession of valued objects having a sentimental interest to the owner comes under a different head of the jurisdiction. Plaintiff's proceeding, while nominally to gain possession of the trophy, is in reality to obtain a reversal of the present award, with a reinstatement of the Premier entry as the winner. Were jurisdiction entertained proof would be naturally taken with respect to the equipment of the 1910 Premier cars from nearly all the large cities of the United States. On this motion, 73 affidavits from 26 cities have been submitted. Upon a hearing on the merits, even with the utmost diligence, such a mass of testimony from widely dispersed points might require several months for its completion. After decision rendered thereon, appeals would naturally follow, so that the final judicial ascertainment of the result of the 1910 Glidden Tour might not be reached until other Glidden tours had in the meantime taken place. Heretofore, the law has declined this jurisdiction not based on those property rights usually cognizable by courts. To change now and hear the loser in court would also imperil the spirit and interest in all such contests.

In the present case, the objections to the form of the appeal and to the proceedings before the Contest Board are largely technical. While in some respects informal, such proceedings do not appear to lack any substantial protection to all concerned. The high standing of the parties forbids the suggestion of fraud; in fact, upon the argument it was acknowledged that there was no fraud as to anyone involved. In the absence of fraud, the question for the court is not whether passing primarily upon the evidence, it would have reached the same conclusion as that of the Contest Board, or whether their conclusion was reasonable or unreasonable, but simply and wholly whether the case before them was so bare of evidence to sustain the decision that no honest mind could reach the same result (People ex rel. Jackson v. New York Produce Exchange, 149 N. Y. 401, 414).

No winner of this trophy has a right to hold it for more than one year, and its ownership remains in the American Automobile Association. There is, therefore, no necessity to impose the terms of a bond conditioned to conform to any future order of this court, as the Association is a responsible defendant able to comply with any final decree.

The temporary injunction is vacated and dissolved, with costs.

September 8, 1910.

Plaintiff Says Fight Will Go On

Harold O. Smith, president of the Premier Motor Mfg. Co. of Indianapolis, entrant of the Premier cars in the recent Glidden tour, telegraphed the following message to THE AUTOMOBILE:

CHICAGO, Sept. 13.—The action of Mr. Justice Putnam in refusing to continue in force the temporary injunction issued in the suit brought by me against the American Automobile Association, Chalmers Motor Company and others, to set aside the decision of the Contest Board and to restrain the delivery of the Glidden Trophy to the Chalmers Motor Company, will have no effect upon the vigorous prosecution of this action.

The statement purporting to have been made by the Chalmers company to the effect that the Supreme Court of New York has awarded the Glidden trophy to the Chalmers Motor Company and has fully sustained the action of the Contest Board, is wholly without foundation in fact.

The decision of the court in no way determines the propriety of the action of the Contest Board or settles the merits of the controversy, nor does it attempt to do so, and the preliminary injunction was refused, apparently upon the theory that the issues cannot be finally determined during the year within which the winner of the 1910 contest will be entitled to the custody of the trophy, and that the A. A. A. is a responsible body, subject to the jurisdiction of the court and can be compelled to comply with the terms of any decree entered.

I have instructed my attorneys to set the case down at the earliest possible date for a hearing on the merits and to proceed without delay to a final determination of the issues involved. Much as I deplore the necessity for this course, I am determined, not alone in my own interest, but in the interests of clean, wholesome sport, to obtain a decision from an impartial tribunal, and if necessary a court of last resort, as to whether or not the Premier cars driven in the 1910 Glidden tour, after having established so conclusively their superiority over all other cars driven in the contest, can be disqualified in the manner attempted and the trophy awarded to a manufacturing corporation not an entrant, in utter disregard, as it seems to me, of the plain provisions of the rules. The fight has just begun. (Signed) H. O. SMITH.

French Rights to Twombly Patents Sold

W. Irving Twombly, of the Twombly Motors Company, has received a cable from Paris announcing the sale of the French patent rights of the Twombly Power Company to Bernard Maimon, the proprietor of *Le Matin* of Paris, France.

Vanderbilt Cup of 1910

THE premier sporting event of American motordom, the Vanderbilt Cup race, will be decided October 1 on the Long Island course of the Motor Cups Holding Company. A magnificent list of entries has been made to date and as the entry box will not be declared closed until September 24, considerable additions are expected.

The course for this year's race is identical in length and territory with that of 1909, but material improvements have been made in the surfaces of certain portions of the route so that higher speed and less tire trouble than ever before are looked for. The course is situated in Nassau County and is 12.64 miles long. Of this distance, 5.15 miles are over one of the fine stretches of the Long Island Motor Parkway and 7.49 miles are county roads. The race requires 22 circuits of the course or 278.08 miles. The start will be at dawn and the finish probably about four hours later.

The history of the event has been glorious. William K. Vanderbilt Jr., a pioneer in American motoring, instituted the cup race that bears his name in 1904 when he offered a trophy to be contested for in a race of from 250 to 300 miles on a road course. Under the conditions the trophy was to be contested for by teams of cars from clubs that were recognized by automobile authorities, and consequently the entrants did not compete as individuals. The same conditions prevailed in the following year.

The first contest took place October 8, 1904, with sixteen starters, representing four teams, those of France, Germany, Italy and the United States. The race was won by a Panhard 90-horsepower car driven by George Heath, a member of the French team, despite the fact that he was an American amateur. The race was 284 miles long and the winner averaged 52 miles an hour and had only a slight margin at the end.

In 1905 a Darracq driven by Hemery was the winner with an average of 61 1-2 miles an hour. In this race Lancia in a Fiat was eliminated as a winning factor while far in the lead, through a collision with a freak car that he thought he could avoid. In 1906 France scored again with a Darracq driven by Wagner with an average speed of 63 miles an hour.

Changing conditions resulted in some radical alterations in the deed of gift covering the Vanderbilt trophy and no race was held in 1907. In the following year, the custody of the cup having been vested in the Motor Cups Holding Company, the race was renewed and on October 24, 1908, a 90-horsepower Locomobile, driven by Robertson, was returned the winner. The average time made by the winning car was 64.3 miles an hour, the fastest time ever made in a cup race under like conditions. In this race, under the amended terms of the deed of gift, the cars competed as individuals.

Last year saw the cup won by a six-cylinder Alco, driven by Harry F. Grant, with an average speed of 62.8 miles an hour for the 278.08 miles of the race. A Fiat, driven by E. H. Parker, was second.

In connection with the big race last year, two shorter sweepstake events were run coincidentally, the Massapequa trophy at 126.40 miles for $1,000 and a cup and the Wheatly Hills trophy at 189.60 miles.

It may be predicted with certainty that there will not be an uninteresting second from the moment the first car is sent away until the last one finishes. Given a pleasant day the attendance undoubtedly will break some records. In the past, the chief item about which there may have been criticism of the management of the contest has been the fact that after the first and second cars finished the race, the spectators swarmed upon the

SIXTH ANNUAL RACE FOR TROPHY, CASH AND HONOR TO BE HELD OCTOBER 1 WITH A STRIKING FIELD OF CARS AND DRIVERS

course and the resulting congestion in the vicinity of the grand stand forced the officials to declare the race off before the rest of the contestants were able to finish.

This crowding resulted in jeopardy for hundreds and was an injustice to the unplaced cars. Take for example the case of a car that is lower in power and price than the winner and second. If that car has an opportunity to be checked in in third or fourth place, and ahead of many other automobiles, the honor of making a creditable run and finishing close to the winner and placed cars is a distinct consideration.

This year a determined effort will be made to give the contesting cars a chance to finish without interference. The conditions of the Vanderbilt Cup Race are as follows:

Open to Class C; divisions 4C and 5C. Division 4C includes gasoline cars or chassis made by a factory which has during the last twelve months prior to the date of the contest produced at least 50 motor cars (not necessarily of the same model). Eligible for entry under piston displacement limitations of Class B, but without minimum weight restrictions. The limits for piston displacement in this class are from 301 to 450 cubic inches.

Division 5C is the same as above, except that the piston displacement limits are from 451 to 600 cubic inches.

Under the terms of the award, if one of the 4C cars wins the cup and cash, the most prominent of the 5C cars will be awarded a special "Donor's Trophy" for permanent ownership.

If the present prospect of twenty-five starters is realized in the cup race and if the starters in the Massapequa and Wheatly Hills trophy races total fifteen, which is said to be a conservative estimate, there will be forty cars in simultaneous action during the early hours of October 1. On as short a circuit as is afforded by the Vanderbilt Cup course this would place the cars about fifteen seconds apart, if they should be separated by regular intervals during any part of the running. The scene at any point along the route is thus bound to be full of action.

The Massapequa trophy race is open to cars of from 161 to 230 cubic inches displacement of Class B, division 2B; minimum weight 1,400 pounds and is ten times around the circuit.

The Wheatly Hills trophy race is for Class B, division 3B, open to cars of from 231 to 300 cubic inches piston displacement.

The entry lists of both sweepstakes events will close September 24. From September 20 to the day of the races practice will be allowed over the course from 5 until 8 A. M., the roads being closed to traffic during those hours.

With a full dozen days more to go before the entry boxes close, the entries for the three races are as follows:

For the William K. Vanderbilt, Jr., Cup—

Practice Number	Car	Driver
1	Benz	Robertson
2	Benz	Hearne
3	Benz	Bruce-Brown
4	Alco	Grant
5	Pope-Hartford	Fleming
6	Pope-Hartford	Dingley
7	National	Aitken
8	National	Livingston
9	Lozier	Mulford
10	Simplex	Mitchell
11	Simplex	Beardsley
12	Marquette-Buick	L. Chevrolet
14	Marquette-Buick	Burman
15	Marqette-Buick	A. Chevrolet
16	Apperson	Hanshue
17	Marmon	Dawson
18	Marmon	Harroun

Recent Events Among Aviators

PRIZES DISTRIBUTED AT HARVARD-BOSTON MEET—AERONAUTIC MILITARY RESERVE—WIRELESS WITH DIRIGIBLES

THOUGH the proportion between spectators inside the pay gates and those outside at the Harvard-Boston aviation meet has generally been as one to two, the first week totaled about a quarter million of paid admissions, it is stated, and it was decided to prolong the event from Sept. 13 to Sept. 15. The city of Boston and the international mining engineer John Hays Hammond have offered money prizes for successful bomb-throwing at a dummy battleship target from altitudes of 1800 feet or higher, the competition to take place on the two additional days of the meet.

Only the Wright machines have competed in the important slow-flight contests scheduled. On Sept. 8 Walter Brookins flew a lap or 5 1-4 miles in 13 minutes 48 seconds. Two days later Johnstone flew 63 miles in 2 hours 3 minutes 5 2-5 seconds and on Sept. 12 he stayed up for 3 hours, 5 minutes, 40 seconds, covering 101 miles, which was record for duration of a single flight. The slowest flight was thus at the rate of 22 3-4 miles per hour. Previously a short flight at the rate of 19 miles per hour had been reported. The record for the shortest getaway on wheels, in which machines with skids cannot compete, was made on Sept. 9 by Graham-White in the Blériot monoplane. A first attempt gave a start in 52 feet 6 inches, the second cut this to 39 feet 10 inches, and finally it was reduced to 26 feet 11 inches. In this contest the power of propulsion and the force of the wind play an important part, while in the slow-flight trials the wind may be eliminated as a factor by prescribing a circular course and the power is unimportant, the whole emphasis being on general efficiency of design and construction. On Sept. 12 Graham-White flew in his Blériot machine from the field at Squantum twice to Boston Light and back, a distance of 33 miles in 34 minutes, 1 1-5 seconds, bettering his speed record of the previous week about 6 minutes, and winning the $10,000 speed prize of the meet without competition. On the same day Lieutenant J. E. Fickel flew with Willard in a small Curtiss biplane and fired with an army rifle at targets on the ground while circling the field at more than 30 miles per hour. Wilbur Wright flew with Brookins and practiced throwing plaster of paris bombs at the imitation battleship, succeeding in scoring 77 points with 37 balls, beating Graham-White's previous record of 75 points. In all, Graham-White won $22,100 in prizes at this meet and the Wright team $9,250. Clifford B. Harmon captured all the amateur first prizes.

Nearly all the prominent aviators at the Boston meet enrolled themselves as members of the United States Aeronautical Reserve, an organization which was founded during the progress of the event by J. H. Ryan, a son of Thomas F. Ryan of New York for the purpose of training many aviators in the art of throwing bombs. A trophy valued at $10,000 and a valuable cup are to be competed for by the members. The organization is to be international in scope and membership, military in purpose.

James H. Moore, an owner of theaters in Rochester, N. Y., and Detroit, Mich., has offered a prize of $10,000 for the first flight between the two cities, the conditions to be decided by a committee of aviators.

Charles K. Hamilton, the aviator who flew from New York to Philadelphia and back this summer, flew at Sacramento, Cal., on Sept. 9 and sustained severe injuries at a fall due, he said, to the jamming of a rudder.

Hawthorne race track at Chicago near the Indiana boundary, has been leased for the meet to be held in Chicago, Oct. 1 to 8 and also for the following week, as a starting ground for contestants in a race from Chicago to New York organized by two newspapers offering a prize of $25,000 for the winner, if any.

At the Harvard-Boston meet on Sept. 10 Glenn H. Curtiss introduced the "Flying Fish," a new biplane of Curtiss-Burgess manufacture, equipped with "Indian" motor and Burgess propeller.

Robert Loraine, an actor, flew on Sept. 11 from Holyhead, Wales, aiming for Dublin, and dropped into the Irish Channel 400 yards from Bailey Lighthouse at the coast of Ireland.

Paris as a municipality offers a prize of $20,000 to any French-born aviator who flies from Paris to Brussels and back on Sept. 26.

The Bayard-Clément, a French military dirigible balloon, has been equipped with a specially light wireless telegraph apparatus and has sent and received messages over a radius of 56 miles.

"America," the dirigble with which Walter Wellman, with a crew of five proposes to cross the Atlantic ocean, is 228 feet long, has a maximum diameter of 52 feet and a volume of 345,000 cubic feet. It has been equipped with a wireless telegraph apparatus for sending and receiving designed by A. F. Collins of New York City. This involves the use of a cable dragging in the sea to act as a grounding wire. The date of departure from Atlantic City, it is stated, will be announced 24 hours in advance, if the weather permits.

Previous altitude records by Brookins. Drexel and Leon Morane were broken by the latter on Sept. 3 near Paris, Morane this time reaching a height of 8,151 feet in a Blériot monoplane.

Prof. A. Lawrence Rotch of Harvard and Blue Hill Observatory is preparing to furnish charts of the normal air currents in different altitudes based on observations made for the past 15 years by means of kites and small balloons. As the work covers a large part of the Atlantic ocean, it is believed that it will greatly assist in crossing this water by dirigible or aeroplane, favorable currents being available as a rule by selection of place and altitude.

According to a press dispatch, Duralumin is a new alloy of aluminum discovered by H. B. Weeks, head chemist at Vicker's Sons and Maxim's Works, Barrow. It is described as a little heavier than aluminum but as strong as steel, and the firm is building new works at Birmingham, Eng., for its production. The discoverer of the alloy declares that it may be rolled, drawn, stamped, pressed and forged and is one-third the weight of brass. Commercial manufacture is to begin in October.

S. A. E. Striding Forward Rapidly

The following were elected, this week, members, associates, and juniors of the Society of Automobile Engineers:

James C. Angelino, Carlson Motor & Truck Co., Philadelphia, Pa.
Edwin E. Arnold, Metal Products Company, Detroit, Mich.
C. P. Brockway, Inter-State Automobile Co., Muncie, Ind.
Wm. G. Bee, Edison Storage Battery Co., Orange, N. J.
Wilton Bentley, Universal Electric Storage Battery Co., Chicago, Ill.
John R. Bensley, Randolph Motor Car Co., Chicago, Ill.
Claire Barnes, Billings & Spencer, Hartford, Conn.
Harold A. Baxter, H. H. Franklin Mfg. Co., Syracuse, N. Y.
Fred C. Burkhardt, The Crosby Co., Buffalo, N. Y.
Everett J. Cook, Faulkner-Blanchard Motor Car Co., Detroit, Mich.
Wm. E. Carpenter, Hibbard Engineering Co., Detroit, Mich.
A. L. Dyke, 3975 Washington St., St. Louis, Mo.
C. A. Erickson, Lozier Motor Co., Plattsburg, Pa.
Radclyffe Furness, Midvale Steel Co., Philadelphia, Pa.
Max H. Grabowsky, Grabowsky Power Wagon Co., Detroit, Mich.
Arthur A. Greenick, McCord Mfg. Co., Detroit, Mich.
Geo. E. Hazard, Hazard Motor Mfg. Co., Rochester, N. Y.
Wm. E. Taupt, L. A. Bergdoll Motor Co., Philadelphia, Pa.
Verne R. Lane, Milan, Mo.
Arthur C. Leverton, Brush Runabout Co., Detroit, Mich.
John McGeorge, Cleveland Motor Truck Co., Cleveland, O.
James A. McMichael, Carpenter Steel Co., Toledo, O.
Cyrus E. Mead, Reibold Building. Dayton, O.
Thos. H. Miller, Grabowsky Power Wagon Co., Detroit, Mich.
Burnett Outten, Packard Motor Car Co., Detroit, Mich.
Clive W. Richardson, Brush Runabout Co., Detroit, Mich.
Elmer R. Ritter, The Lunkenheimer Co., Cincinnati, O.

Preparing for Garden Show

EXHIBITORS DRAW FOR SPACES—MAIN HALL TO BE MUCH ENLARGED—TO CONTINUE FOR TWO WEEKS, THE FIRST FOR PLEASURE CARS ONLY

PREPARATIONS for the coming eleventh national automobile show at Madison Square Garden next January were discussed and in large measure perfected at a meeting of the board of managers of the A. L. A. M. last week. The meeting was well attended and its proceedings harmonious.

The business transacted included drawing for space on the main floor and in exhibition hall and the balconies. The floor space will be materially increased through rebuilding to a large extent the interior of the main hall.

The show will be divided into two parts, one devoted to passenger or pleasure vehicles and the other to freight or commercial cars. The first section will hold forth from January 7 to January 14 and the second will occupy the following week.

The first to draw for space was the Buick, followed by the Overland, E-M-F, Cadillac, Packard, Maxwell, Chalmers, Reo and Pierce-Arrow. The other cars which will occupy space on the main floor are as follows: Stearns, Thomas, Olds, Franklin, Dayton, Oakland, Lozier, Elmore, Winton, Locomobile, Hudson, Mitchell, Stevens-Duryea and Peerless.

Cars in the exhibition hall and balconies will include the following makes: Amplex, Moon, Mercer, Corbin, Bartholomew, Nordyke & Marmon, Knox, American, Matheson, National, Selden, Buckeye, Moline, Premier, Autocar, Columbia, Alco, Studebaker, Waltham, Inter-State, Ohio, Palmer & Singer, KisselKar, Hol-Tan, Chadwick, Speedwell, Regal, McIntyre, Marquette, Acme, Pierce-Racine, Flandrau, Hupmobile, Midland, Brewster, Courier, Simplex, Atlas, Dorris and Cartercar.

The show committee, which consists of Col. George Pope, chairman; Charles Clifton, Alfred Reeves and M. L. Downs, has devised an elaborate plan of decoration.

It was announced that a meeting will be called in the near future to allot space to accessory dealers and exhibitors of commercial or freight carrying cars, electric vehicles and motorcycles which will comprise section two of the show.

The Kissel Motor Car Company, of Hartford, Wis., was granted a license under the Selden patent at this session.

Charles Clifton, of the Pierce-Arrow Motor Car Company, head of the association, presided at the meeting, and in attendance were: James Joyce, American Locomotive Company; G. H. Strout, Apperson Brothers Automobile Company; J. S. Clarke and D. S. Ludlum, Autocar Company; O. Y. Bartholomew and R. A. Whitney, The Bartholomew Company; J. W. Lambert, Buckeye Manufacturing Company; W. C. Leland, Cadillac Motor Car Company; Hugh Chalmers and C. C. Hildebrand, Chalmers Motor Company; H. W. Nuckols, Columbua Motor Car Company; M. S. Hart, Corbin Motor Vehicle Corporation; W. R. Innis, E-M-F Company; G. H. Stillwell, H. H. Franklin Manufacturing Company; Elwood Haynes, Haynes Automobile Company; Howard E. Coffin, Hudson Motor Company; I. H. Page, Stevens-Duryea Company; G. A. Matthews, Jackson Automobile Company; A. N. Mayo, Knox Automobile Company; S. T. Davis, Jr., Locomobile Company of America; H. A. Lozier, Lozier Motor Company; F. F. Matheson, Matheson Motor Car Company; Benjamin Briscoe, Maxwell-Briscoe Motor Company; W. T. White, Mercer Automobile Company; W. E. Metzger, Metzger Motor Car Company; J. W. Gilson, Mitchell-Lewis Motor Company; W. H. Van Dervoort, Moline Automobile Company; M. J. Budlong, Packard Motor Car Company; L. H. Kittridge, Peerless Motor Car Company; Charles Clifton, Pierce-Arrow Motor Car Company; George Pope, Pope Manufacturing Company; H. O. Smith, Premier Motor Manufacturing Company; T. C. O'Connor, Pullman Motor Car Company; R. E. Ingersoll, Reo Motor Car Company; George J. Durham, Royal Tourist Car Company; G. E. Mitchell, Alden-Sampson Manufacturing Company; R. H. Salmons, Selden Motor Vehicle Company; F. B. Stearns, F. B. Stearns Company; W. R. Innis, Studebaker Automobile Company; Windsor T. White, Waltham Manufacturing Company; John N. Willys, Willys-Overland Company; Thomas Henderson, Winton Motor Carriage Company; Alfred Reeves, general manager.

Maxwell Wins First Buffalo Reliability

BUFFALO, Sept. 12—Maxwell car No. 12, Charles F. Munroe, driver, won the Laurens Enos trophy in the first annual reliability contest of the Automobile Club of Buffalo.

The winner was in the class selling for from $1,201 to $1,601, and showed a record of a perfect road score and only 5 points penalization in the final technical examination by the representative of the three A's.

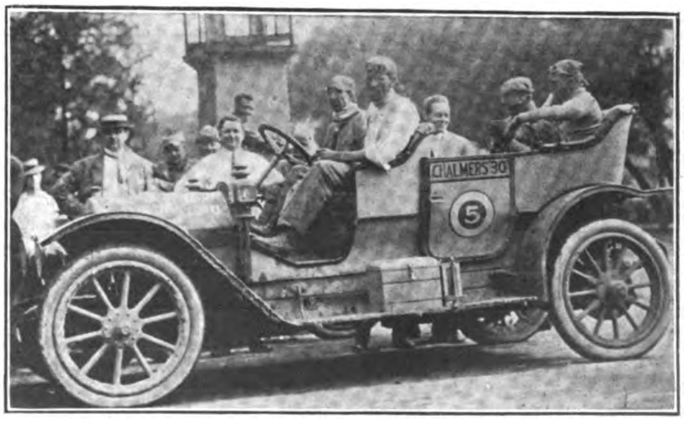
The Hudson car, Tate driver, was second, having a technical penalization of 5 points, but losing by road penalty of 4 points. Oakland No. 7 was third, with a total penalization of 32 points, and the two Pullmans were tied for fourth honors with 36 points.

The first day's run knocked out five of the entries from the clean score class. These were Regal No. 2, three points; Maxwell No. 11, 22 points; Regal No. 14, 2 points; Reo No. 15, 21 points, and Oakland No. 18, 28 points.

The second day's run to Salamanca, took Parry No. 1 from the clean score class, and added 6 points to the Regal, three to the Maxwell and 30 to the Oakland, all three of which were penalized on the first day's run. The third day's run to Geneseo and return took the other Oakland and Hudson from the clean score class and added 7 points to the Parry No. 1, 47 to Maxwell No. 11, 42 to Regal No. 14, and placed 3 and 2 points respectively against the Hudson and Oakland.

The total road score was as follows:

No.		Wednesday	Thursday	Friday	Saturday	Total
1	Parry	0	3	7	4	14
2	Regal	3	6	0	0	9
4	Pullman	0	0	0	0	0
5	Pullman	0	0	0	0	0
7	Cartercar	0	0	0	0	0
11	Maxwell	22	3	47	14	86
12	Maxwell	0	0	0	0	0
14	Regal	2	0	42	0	44
15	Reo	21	0	0	0	21
17	Oakland	0	0	3	0	3
18	Oakland	28	30	0	0	58
20	Hudson	0	0	2	1	3



Chalmers No. 5 as it entered Chicago from the Glidden Tour—now declared winner

Motordom's Supreme Court

MANUFACTURERS' CONTEST ASSOCIATION SUGGESTS SUCH A BODY AND DISCUSSES CHANGES IN COMPETITION RULES FOR COMING YEAR

A SUPREME COURT of motordom was foreshadowed Friday at the meeting of the General Rules Committee of the Manufacturers' Contest Association, which was held at A. L. A. M. headquarters, when a Board of Appeals the function of which will be to review the findings of the Contest Board on appeal was suggested, discussed and referred to the directors for action.

One of the factors that worked to bring the matter to a focus was the dissolution of the temporary injunction given to the Premier company against the Contest Board, to prevent the latter body from turning over the Glidden 1910 Trophy to the Chalmers Motor Car Company. The decision followed the general line always taken by the Courts in ruling upon matters of sport—that is, it refused to upset the action of a duly constituted and authorized sport-governing body.

The contemplated Board of Appeals would serve to supply an ultimate tribunal such as was sought by the appellants in the various cases taken into the equity courts this year.

About twenty-five were in attendance at the meeting, which was presided over by Howard E. Coffin, president of the Hudson Motor Car Company. Alfred Reeves, S. M. Butler and A. L. McMurtry were present in an advisory capacity.

One of the matters that came up for consideration was a modification of the weight rule so that Ford cars and others of similar weight and power shall be rendered eligible.

The announcement was made that at the end of the current racing and contest season Alden L. McMurtry, chairman of the Technical Committee of the Contest Board, would retire permanently from that position, which he has filled acceptably.

Among the matters taken up by the committee were the following: That the decision of the Technical Committee shall be final with regard to the eligibility of any car to enter contests under the rules of the Contest Board; that importers shall be considered upon an even basis with domestic manufacturers in stock car and stock chassis events; that amateur drivers shall lose their standing as such by competing with professionals on track or road; that promoters shall charge certain amounts for entry; that entrants shall report to the starter or his assistant at least thirty minutes before the scheduled time of the first event of any race meeting; that an effort shall be made to interest the United States Signal or Engineer Corps as observers in national reliability tours; that a paid Technical Committee be placed at the disposal of the Contest Board next year; as to the use of demountable wheels; the length of time during which race drivers may continue at the wheel during long-distance events, such as 24-hour races, and several other matters.

Those who attended the session were as follows: Howard E. Coffin, A. N. Jervis, George H. Strout, G. W. Brown, Jesse Froelich, George Dunham, Herman G. Farr, A. L. Riker, C. A. Emise, F. F. Matheson, C. W. Matheson, M. C. Reeves, William G. Metzger, George M. Dickson, Homer George, H. O. Smith, W. B. Hurlburt, W. H. Vandervoort and Russell A. Field.

While the action taken by the committee is not formally final, the subsequent proceedings upon matters recommended and formulated is considered largely perfunctory on the part of the Contest Board.

Automobile Expense and Record Book

One of the latest innovations for the autoist who wants to know just what it costs to maintain his car is offered by H. C. Smith & Company, 61 Cliff Street, New York City. A pair of pages from the book are here reproduced and they will tell the story better than words. The book is 3 1-4 x 5 inches; opens endwise, and has enough pages to last for a whole year. The title page provides space for the name and number of the automobile, owner's name, also his address, the name and address of the chauffeur is provided for, and a space is given for the registration number of the car.

The idea incorporated into the Automobile Expense and Record Book as here referred to, has a utility foundation. A record such as this will be of value in determining the ratio of lubricating oil to gasoline, for instance. In the course of time it would be possible to decide as to whether or not it is an economy measure to repair tires to the greatest possible extent, or to avoid the cost of repairs and transfer the account to the purchasing fund with the idea of buying new tires more frequently. In the garage there are little problems to solve and this method of accounting will permit of reaching a decision as to the amount of money the garage keeper becomes the possessor of, some of which is for rental, to be sure, and the balance for articles purchased, and repair work done. Some garage keepers have a happy way of coaxing money out of the pocket of the automobile owner, and this little book would help to tell the tale should they succeed. Many owners in figuring on the cost of maintaining a car make the mistake of assuming that $30 per month, for instance, will be the total of the garage increment. With an efficient "coaxer" in charge of the garage it is possible to see $30 in the position of the small end of the horn.

Motor Day at State Fair

MINNESOTA GRANGERS ADD INTEREST TO THEIR EXHIBITION BY PUTTING ON A PROGRAM OF AUTOMOBILE RACES

MINNEAPOLIS, MINN., Sept. 12—Motor day at the State Fair, Saturday last, was of greater importance than such affairs usually are. The feature was the track meet and because of the prizes offered by the State Fair people many racing stars were attracted. The Benz captured the mile track record, beating the Fiat's previous best of 50 4-5. The big Benz did 49:25; the Fiat, 49:35; the Darracq, 49:78, and the Buick Special, 50:61.

In addition to the record trials there were seven events contested, two of which were won by the Buick and one each by the Marquette, Fiat, Ford, Velie and Falcar. The feature of this section was the 5-mile free-for-all in class D in which the Fiat, Buick and Darracq met. This battle resulted in a victory for the first-named by a scant 2 seconds over the Buick, with the Darracq the same margin behind the place winner. Another free-for-all brought together some smaller cars and resulted in a victory for the Velie. Oldfield in his Knox started in this event and figured among the also-rans. The summaries:

One mile time trials—

No. Car	Driver	Time
5—Benz	Oldfield	:49.25
2—Fiat	De Palma	:49.35
6—Darracq	Kerscher	:49.78
19—Buick	Burman	:50.61

Class B, Division 2—161-230 Class, 5 miles—

9—Buick	Burman	5:11.36
7—Firestone-Columbus	L. A. Frayer	5:19.82
20—Cole 30	B. Endicott	5:20.12
21—Cole 30	G. Edmunds	5:22.25
8—Buick	Chrevolet	5:35.20
15—Staver-Chicago	Monckmeier	5:35.30
14—Staver-Chicago	Crane	5:50.10
10—Hudson	Gullic	5:56.30

5 miles—Free-for-all, Class D—

2—Fiat	De Palma	4:29
19—Buick	Burman	4:31.39
6—Darracq	Kerscher	4:33.12

5 miles—Handicap, Class E—

12—Ford	Hanson	:15	6:10.14
10—Hudson	Nyman	:25	6:26.54
25—Pullman	Hegland	...	6:47.45
24—Velie	Harford	:35	6:56.53

5 miles—Free-for-all, Class D—

24—Velie	Harford	5:57.93
15—Staver-Chicago	Monckmeier	6:10.68
20—Cole	Endicott	6:17.43
21—Cole	Edmunds	6:17.88
25—Pullman	Hegland	6:25.74
14—Staver-Chicago	Crane	....
1—Knox	Oldfield	6:29.25
22—Cutting	Clark	6:45
7—Firestone-Columbus	Frayer	6:48.73
28—Falcar	Gelnaw	....

5 miles—231-300 class, Class B, Division 3—

28—Falcar	Gelnaw	5:19.80

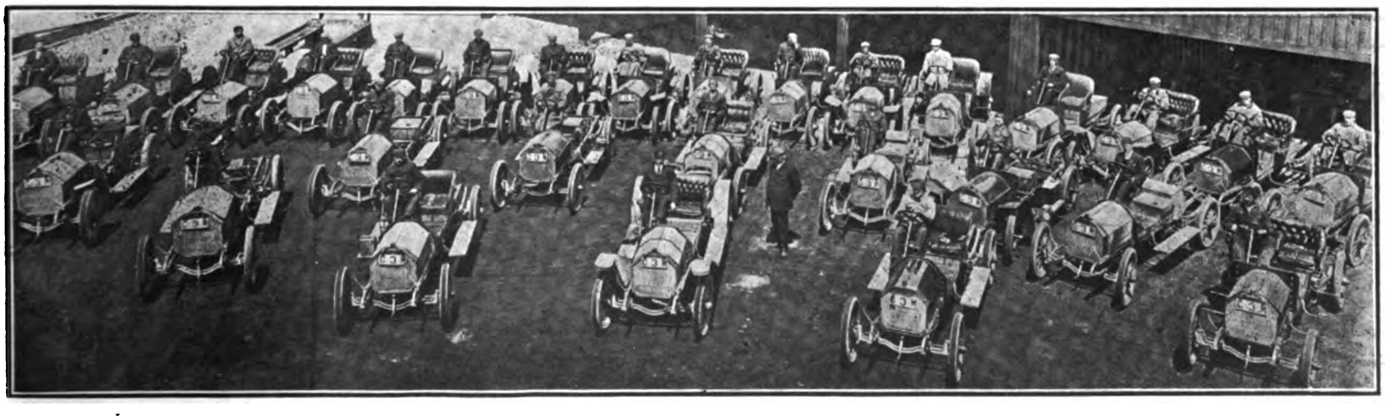
Third Annual Good Roads Convention at St. Louis

Delegates to the third annual Good Roads Convention, to be held at St. Louis, September 28, 29 and 30, will, besides listening to the opening address by Lewis R. Speare, have the opportunity of hearing read many excellent papers germane to the subject. Among them will be: "High Altitude Roads," F. L. Bartlett, Denver, Colo.; "Roads for Modern Traffic in the South," J. T. Bullen, Montgomery, Ala.; "Paved Roads," A. N. Johnson, State Engineer, Springfield, Ill.; "Modern Road Construction in the United States," Walter Wilson Crosby, Chief Engineer, Maryland Geological Survey; "Continuous and Systematic Road Maintenance," S. Percy Hooker, Chairman N. Y. State Highway Comm., Albany, N. Y.; "Farmers' Interest in Improved Highways," Hon. N. J. Batchelder, Master of National Grange, Patrons of Husbandry; "City Streets and Boulevards," Hon. James C. Travilla, Street Commissioner of St. Louis, Mo.; "Modern Surface Treatment of Various Roads," Charles W. Ross, City Street Commissioner, Newton, Mass.; "Town and Lateral Roads," Frank D. Lyon, Department Highway Commissioner of N. Y. State; "State Roads to Meet Modern Traffic Conditions," Harold Parker, Chairman Mass. Highway Commission; "Dustless Roads of Europe," Arthur Blanchard, of the Department of Civil Engineering, Brown University, Providence, R. I.; "Park Roads," John R. Rablin, Engineer, Metropolitan Park Comm., Boston, Mass. and several others.

The plans for the entertainment of the delegates are in the hands of the local committee, and include boat and trolley rides and the inspection of many of the industries of the city of St. Louis.

Studebaker Automobile Company Will Move

When a representative of THE AUTOMOBILE conferred with the Studebaker Company in relation to the question of moving, while the main fact was not denied, it was said that the New York building now occupied by the Studebaker Company is to be turned into a hotel, and it was learned through other sources that the company will probably move to a new building in the vicinity of Fifty-second street and Seventh avenue.



At the Locomobile Plant—Starting out the testing crews in the morning

Doings in the East

BOSTON TAXICAB COMPANIES TO INCREASE RATES—JERSEY MOTORISTS' INTERESTS INJURED BY SEVERE LEGISLATION—GOOD WORK OF SYRACUSE CLUB—TRADE NOTES

—The Lozier sales company of Boston has added T. A. Earl, formerly a Maxwell-Briscoe salesman, to its sales force.

—The Boston *American's* commercial vehicle contest will be held Oct. 20-21 instead of Oct. 14-15 as first announced.

—W. J. Jameson, who handles the Selden car in Boston, has just taken the Moline on, having secured a large territory for its sale.

—The Ingram-Richardson Enamel Company, of College Hill, Beaver, Pa., has orders on its books now for automobile tags for 1911 to total more than 500,000.

—The Reo Company has enlarged the territory of J. M. Linscott of Boston, who had all Massachusetts, giving him in addition Vermont and New Hampshire.

—The New Jersey Automobile and Motor Club has formulated a demand for the strengthening of the law which requires lights upon all horse-drawn vehicles after dark.

—The Keystone Sheet Metal Company of Ambridge, Pa., has completed its first lot of gasoline tanks for the Franklin Commercial Truck Company of Franklin, Pa.

—Fifty entries are already in for the *Herald* Sociability run, at Syracuse, N. Y., which is to be held Sept. 24. It is expected that there will be over 100 entries for it.

—Jack Wade, formerly automobile editor of the Boston *Journal*, has accepted the position of sales and advertising manager of the Grout Automobile Company, Orange, Mass.

—Manager J. E. Savelle, of the New England Motor Vehicle Company, agents in Boston for the Parry and Rainier cars, has resigned to take charge of a big garage to be built soon in the Hub.

—J. F. Dunlop, of the Dunlop Motor Co., Kilmarnock, Scotland, has contracted with the Motor & Mfg. Works Co., Geneva, N. Y., to manufacture on a royalty all Ejector mufflers used in Great Britain.

—C. J. Conolly, 443 Central Park West, New York City, is the local representative of the Randall-Faichney Company, of Boston, makers of the Jericho Horn "B"-Line Oil Gun and "Webster" Gasoline Gauge.

—Finishing touches are now being given to the first car manufactured at the Poughkeepsie plant of the F. I. A. T. Co. It is expected that machines will be turned out by the plant from now on, at the rate of one a day.

—A new company, headed by L. H. Wetherell, has been organized in Boston to handle the entire wholesale and retail business of the Croxton-Keeton car in New England. It is known as the Croxton Motor Car Company of Boston.

—The Cunningham Piano Company, of Philadelphia, has just put into operation a Hewitt motor truck, the capacity of which is 4,000 pounds. The truck hauls seven large pianos at one time and is expected to greatly facilitate rural and suburban delivery.

—G. D. Woodworth, formerly in charge of the Electric Pleasure Vehicle Department of the Philadelphia Studebaker branch, has been placed at the head of the Studebaker's E-M-F and Flanders "20" department on 18th below Spring Garden street.

—The race meeting scheduled for Sept. 9 and 10 at Providence, R. I., was declared off by its promoters. The projected meet was to have been a local affair if it had been conducted, as no application for sanction was made by the promoters to the Contest Board.

—The Central City Motor Car Company has been incorporated to handle the Haines car in Syracuse and Central New York. The president is A. G. Williams, of Syracuse; Arthur Hughes, of Elbridge, is treasurer and manager, and W. Curtis, also of Elbridge, is secretary. Temporary quarters are at 376 W. Fayette street.

—Richard G. Spavin, whose plant is located on Centre avenue, Pittsburg, has secured Arthur McClure from the Inter-State Sales Agency and Edward Gilmore from the Franklin automobile factory, of Syracuse, making a strong addition to its business force.

—A new firm has just been organized in Boston known as the McConnell & McCone Company to handle the Overland, formerly sold by the J. M. Linscott Company. Frank F. Wentworth, at one time New Hampshire agent for the Overland, is to be general distributer.

—All the motor clubs of New Jersey, representing as they do 25,000 automobile owners, are determined to elect to the Legislature this Fall only such men as will favor reciprocal laws, entitling tourists of other States to use the roads, without expense, for a limited period.

—The majority of the Worcester, Mass., dealers have received their 1911 models and had them on display for the first time at the Worcester Licensed Automobile Dealers' Association outdoor auto show, held in connection with the New England fair in that city.

—A change has been made in handling the Jackson car in Boston, E. P. Blake, who has had it for several years, turning it over to W. H. Bates, of Brockton. Mr. Bates had the Brockton agency for a long time. Mr. Blake is to devote his time to the commercial field with the McIntyre truck.

—The Automobile Club of Indian county, Pa., through Judge John P. Elkin, has offered $300 in cash in five prizes to those supervisors who would, during the remainder of this season, put the roads in their charge into the best possible condition. The prizes are $100, $80, $60, $40 and $20 respectively.

—The Worcester (Mass.) Automobile Club, acting with the other auto clubs of the State of Massachusetts, has started a campaign to get men from Worcester county in the Massachusetts Legislature who are favorable to the light bill which will compel vehicles as well as autos to carry lights at night.

—H. W. Brown, proprietor of the Binghamton Motor Car Company at Binghamton, N. Y., has begun work on a large garage. The size of the building is 66 by 130 feet, three stories in height. The building will be practically fireproof and fitted with modern appliances. The total cost will be about $26,000.

—Dr. H. L. B. Ryder of Poughkeepsie, N. Y., has let contracts for the construction of the first airship dock between New York City and Albany. G. Leslie Ryder is designing the garage and airship wharf. The work is to be rushed to completion; and the airship landing is to be large enough for either aeroplanes or two liners of the huge Zeppelin type.

—All is in readiness for the automobile races, in connection with the New York State Fair, which will be held at Syracuse, Sept. 17. Theodore Roosevelt will be a fair visitor that day and will act as honorary referee. There are three National entries and the Herreshoff and Maxwell teams are entered. There are a number of local entries, too.

—The legislation to be striven for by the New Jersey automobilists at Trenton next winter includes the elimination of the present fee of $1 from tourists, the proper enforcement of the light law, compelling all vehicles to carry lights at night, the grading of cars by the A. L. A. M. rating and not upon the manufacturer's rating, and the erection of sign posts.

—Earl J. Moon, sales manager of Moon Motor Car Company, will continue to make his headquarters in New York City, looking after the wholesale selling end of the Moon business in the

East. His latest big deal was in closing with the Linscott Motor Car Company, of Boston, for 250 cars. This concern has been allotted the New England States as its territory for 1911.

—Hartford Solid Motor Tires have been selected by the Wanamaker firm, of New York and Philadelphia, as regular equipment on its complete line of delivery wagons. The excellent service which the Hartford tires have given in the past, the splendid wearing qualities and the economy in actual use brought about the selection of this tire for the Wanamaker trucks.

—The Collins Gear & Motor Company has purchased the plant of the Simpson Stove & Mfg. Co. at Canonsburg, Pa., and will convert it into a factory for the manufacture of automobile axles, gears and motors. The company will also erect a building 60 x 300 feet. The officers are: J. J. Flannery, president; D. P. Collins, vice-president and manager; J. M. Flannery, secretary, and H. A. Neeb, treasurer, all of Pittsburg.

—The Automobile Club of Syracuse has put up this season nearly 200 steel-enameled route and danger signs in the adjacent territory and many special signs have been secured to warn tourists of dangerous places and to give information. The club employs a man and team constantly to post the notices. The territory covered stretches to Richfield Springs, 63 miles from Syracuse, and north to Henderson Harbor, about 60 miles away.

—The New Jersey Automobile and Motor Club contends that the business interests of the State are being greatly injured by the severe motor vehicle laws now upon the statutes. At a recent mass-meeting, called for the purpose of outlining a course of action that would procure remedial motor legislation from the next Legislature, it was pointed out that the automobile has resulted in the increase of the output of a great many New Jersey products.

—The Buick car is now represented in Hartford and Tolland Counties, Conn., by the Buick Garage Company, which for the present is located in the old Rambler quarters at No. 18 Elm street, Hartford, Conn. The Buick was formerly handled by the Miner Garage Company and later by an offshoot of that outfit, the Hartford Garage Company. Edwin Graham, representing the Buick interests, has been in Hartford for the past few days closing up the new deal.

—Harry M. Bronner, widely known in motordom, has assumed his duties as General Eastern Sales Manager of the Dayton Motor Company at the New York offices on West Fifty-seventh street. He will handle the Stoddard-Dayton line not only in New York but through branch houses in Brooklyn, Newark and other points. R. T. Newton will have charge at Newark and E. C. J. McShane at Brooklyn as soon as the new building in that borough is completed.

—At a meeting of the stockholders of the Chase Motor Truck Company the following were elected for the ensuing year: A. M. Chase, Syracuse, N. Y.; A. C. Chase, Syracuse, N. Y.; L. O. Bucklin, Little Falls, N. Y.; Geo. A. Brockway, Homer, N. Y.; H. P. Bellinger, Syracuse, N. Y. At a meeting of the directors immediately following the stockholders' meeting, the following officers were elected: A. M. Chase, president; H. P. Bellinger, vice-president; E. A. Kingsbury, secretary.

—The Boston taxicab companies have been granted an increase in rates, but not as fully as they petitioned police commissioners for two weeks ago. Beginning Sept. 20 the companies may charge 40 instead of 30 cents for the first half mile. The 10-cent limit for each quarter thereafter remains the same. A rate of 50 cents for the first half mile was asked for. For each person in excess of one they may charge 20 cents each. The waiting time for which 10 cents was charged, six minutes, remains the same, the companies asking to have it reduced to four minutes.

—Control of the R. L. M. Morgan Company, motor truck builders, of Worcester, Mass., has passed into a group of New York capitalists headed by Clair Foster, water registrar of New York City, and former managing director of the Standard Plunger Elevator Company. Ralph L. Morgan, founder of the business, will be vice-president of the concern and will have charge of the designing and engineering departments, while Henry E. Whitcomb, the present treasurer of the Morgan company, will continue in the same capacity, with Henry Mason Smith, of New York, as assistant. Henry Bennett Leary, of New York, will be the new secretary, and the board of management will include the following: Frederick A. Philips, Thomas H. Greenwood and Conrad N. Pitcher, all of New York, and John E. Bradley, R. L. Morgan and H. E. Whitcomb, of Worcester.

Middle West News

MINNEAPOLIS SELECTED AS NORTHWESTERN HEADQUARTERS FOR THE FRANKLIN—LOZIER MOVES TO DETROIT NOVEMBER 1—MANY NEW COMPANIES FORMED—INTERESTING ITEMS OF TRADE NEWS

—The Behen-Faught Motor Car Company has secured the St. Louis agency for Michelin tires.

—The St. Louis Automobile Company, 2714 Lafayette avenue, has become the agent for the Clark cars.

—The Hoard Motor Car Company of Galion, Ohio, is taking bids on an automobile factory to cost $60,000, from plans by Architect Vernon Redding of Mansfield, O.

—E. W. Arbogast has severed his connection with the Badger Motor Car Co., and has become associated with the DeTamble Motors Co., as designer and general manager.

—The United Motor Detroit Company, formerly the Maxwell-Briscoe-McLeod Company, will have a branch store in Saginaw, where it will handle Maxwell and Columbia cars.

—Ralph Owen, general manager of the Owen Motor Car Company, and Mrs. Owen, are back from a 2,500-mile tour through the East, covering a period of two weeks.

—W. H. Lalley, European representative of the E-M-F Company, left recently for a trip which will include a swing around the circuit of both the British Isles and the Continent.

—An outgrowth of the Twin City Taxicab Company, the Alco Motor Car Company, of Minneapolis, has been organized to handle the Hudson, Baker and Alco in that territory.

—The Auto Shop Company, of Cleveland, in addition to its handsome new Euclid avenue salesrooms, has taken a long lease on the Fishel building, next door to its Vincent avenue garage.

—The National Gas & Gasoline Trades Association will meet in annual convention at Racine, Wis., one of the centers of the motor car industry in the West, on Dec. 12, 13, 14 and 15, 1910.

—The Haynes Automobile Company of 219 South Sixth street, Minneapolis, has been appointed territory distributor for the Cole "30." They will cover Minnesota and North and South Dakota.

—Morgan & Wright have decided to open a branch store in Denver located in the Majestic Building, 217 Sixteenth street. James Maginnis and Henry Althens have been put in charge of the new branch.

—The Chicago office and headquarters of the Bosch Magneto Company has been removed to 119-121 East Twenty-fourth street. The building is a two-story structure between Michigan and Indiana avenues.

—Interest in Detroit is for the time being focused on the automobile show which will be one of the big features of the State fair, opening September 19. The exhibit will be located in the handsome new building.

—The Regal Motor Car Company, of Detroit, has recently placed at the head of the sales department George D. Wilcox. Mr. Wilcox goes to Detroit from Syracuse, where he has been handling the Regal cars.

—Detroit may be chosen as the location of a plant for the manufacture of a new style transmission perfected by Clark W. Parker, of Springfield, Mass. Officials of the company are in the city looking for a factory site.

—The Rogers Unika Wheel Company, of Boston, is another prospective addition to the Detroit automobile colony. An option has been taken on a large tract of land, and it is the intention of the company to build a large plant.

—The Weber Implement Company has opened downtown salesrooms in St. Louis at Nineteenth and Locust streets, where the Mitchell, Lozier, and Rapid lines are displayed. The main offices will remain at 415 North Main street.

—Louis Geyler has been appointed agent of the Hudson car in the Chicago territory for the coming year. The agency is located at 1532 Michigan avenue until the new building between Twenty-fifth and Twenty-sixth streets is completed.

—Ralph W. Keeler has resigned as general manager of the Keeler-Hupp Company, Detroit, State distributors of Hupmobiles, and will engage in another line of business, retaining his present connections until a successor has been selected.

—The promoters of the Lisbon Auto Truck Company, of Lisbon, Ohio, which was all but ready to start work on a new plant there, are now negotiating for terms in East Liverpool, Ohio, where it is possible the new plant may be located.

—The Missouri Taxicab Company has been incorporated in St. Louis, with Walter Isaacs, 131 shares; Herman Rindskop, 116 shares; Clara Isaacs, 1 1-2 shares, and Addie Rindskop, 1 1-2 shares, incorporators. The paid-up capital stock is $25,000.

—The Studebaker Automobile Company this week shipped the last train load of electric delivery wagons to Gimbel Brothers, New York. This is the last of an order for 66 machines placed by the Gimbels with the Studebaker concern a few months ago.

—The Scioto Auto Company, organized recently with an authorized capital of $150,000, of which $85,000 has been subscribed, will take over the plant of the Arbenz Furniture Company at Chillicothe and will remodel it into an up-to-date automobile plant.

—Racine (Wis.) stockholders in the Thomas Brass & Iron Company and allied companies failed to win their fight to have the plants locate at Racine. The factories at Waukegan, Ill., were destroyed by fire recently. They will be rebuilt at Chicago Heights.

—The Bower Roller Bearing Company is erecting a new plant at Goethe and Hart avenues, Detroit, which will be ready for occupancy this fall. It is to be of concrete construction, 220 feet long, 90 feet in width at the widest point and 60 at the narrowest.

—The Regal line of automobiles, which has been handled up to the present in St. Louis by the General Motor Car Company, will in the future be taken care of by the Grand Motor Car Company, an organization that has just been completed by R. W. Anslem.

—The third annual meeting of the stockholders of the Royal Tourist Car Company for the election of directors and the transaction of business generally will be held on Wednesday, September 21, at 533, Society for Savings, Cleveland, Ohio, at 11 o'clock a. m.

—The crowning feature of last week's convention of Ford Motor Company branch managers from all over the United States and Canada, and from abroad, was the dinner given Wednesday evening in the new convention hall of the Hotel Pontchartrain, Detroit.

—Minneapolis will collect taxes next year on $1,425,300, representing the assessment on automobiles. There are 2,630 machines on the tax lists this year, compared with 1,325 last year. The average of valuations also has jumped. Last year it was $513; this year it is $542.

—The Cummings Auto Sales Company, organized recently with an authorized capital of $20,000, has taken the salesrooms at 153 North Fourth street, Columbus, Ohio, formerly occupied by the Burdell Auto Sales Company. The company will have the Central Ohio agency for the Elmore.

—The Lisbon Auto Truck Company has been formed with a capital of $50,000 and will build a plant at Lisbon, Ohio, for the manufacture of small motor trucks for the use of grocers, hucksters, etc. Among those most largely interested are A. H. Wyatt and W. A. Kitto of Cleveland, O.

—The new officers of the Ideal Electric Company are as follows: Bruce Borland, president; Edwin W. Ryerson, vice-president; Uri B. Grannis, treasurer; Cyrus H. Adams, Jr., secretary, and C. J. Holdrege, general manager. The capital stock of the company has been raised to $50,000.

—The Pierce-Racine car, manufactured by the Pierce Motor Company of Racine, Wis., will hereafter be known as the Case and will be distributed exclusively by the J. I. Case Threshing Machine Co. of Racine, the oldest builder of traction and threshing machinery in the United States.

—The Enger Motor Car Company, of Cincinnati, manufacturer of the Enger automobile, has closed contracts with the Federal Motor Car Company, of Chicago, for 200 cars for 1911. The representative of the Federal company, after visiting the Enger plant, decided to handle the Enger in the Chicago territory.

—The Rubber Products Company of Barberton, O., has increased its capital stock from $150,000 to $300,000. Part of the stock will be given to the stockholders as a stock dividend, and the remainder sold at par pro rata. The increased capital will be devoted to increasing the size and equipment of the plant.

—At the annual meeting of the Firestone Tire & Rubber Company, of Akron, held recently, the old board of directors was re-elected and officers were selected as follows: H. S. Firestone, president and general manager; Will Christy, vice-president; S. G. Carkhuff, secretary, and J. G. Robertson, treasurer.

—The American Tire and Rubber Company of Akron, Ohio, was incorporated with an authorized capital of $200,000 to manufacture and sell all kinds of rubber articles, including automobile and motorcycle tires. The incorporators are: Frank L. Kryder, Adam Duncan, Gilbert C. Waltz, Harvey Musser and J. R. Huffman.

—Minneapolis has been selected by the H. H. Franklin Company of Syracuse, N. Y., as headquarters for their northwestern traveling representative, George S. Rule. His territory includes Minnesota, North and South Dakota, Wisconsin and Northern Michigan, and he has established headquarters at Robertson Motor Company's office at 111 Tenth street, South.

—The Scioto Auto Car Company of Chillicothe, recently incorporated, has been organized by the election of the following directors: Fred G. Stroehmann, Henry J. Arbenz, C. A. Fromm, H. C. Ogden, Wheeling R. Enderlin, Robert W. Manly and F. C. Arbenz. Fred G. Stroehmann was elected president; W. R. Enderlin, vice-president and F. C. Arbenz, secretary and treasurer.

—In accordance with a State requirement the United States Motor Company, Jersey City and Detroit, capital $30,000,000, has filed articles of incorporation with the Secretary of State at Lansing. Other concerns to follow suit are the Alden Sampson Manufacturing Company, Pittsfield, Mass., and Detroit, $300,000, and the G. & J. Tire Company, New York and Detroit, $10,000.

—The McLeary Engineering Company has been incorporated at Toledo by Edward McLeary, Oliver P. Barnhart, Reuben Y. Barnhart, Samuel J. Logan and John F. Kumler, Jr. It has an authorized capital stock of $25,000 and will take over and expand the business of Ed. McLeary, who for years has conducted a machine shop. Both air and auto motors will be added to the output of the concern.

—Studebaker Bros. Manufacturing Company has opened a temporary automobile branch in St. Louis at Tenth and Locust streets in the building formerly occupied by the Midland Automobile Company. Until recently the branch in St. Louis was conducted under the name of the E-M-F Automobile Company, but by present arrangements the Everitt-Metzger-Flanders Company merges its interests in this territory. T. L. Hausmann is manager of the Studebaker company.

—The removal of the general offices of the Lozier Motor Company to Detroit, Michigan, will occur Oct. 1, on the completion of the new factory at Detroit. F. C. Chandler, formerly manager of the Western Sales Agencies and foreign department, has been elected to the vice-presidency of the company, and will be in charge of the sales department; C. A. Emise assumes charge of a new department of publicity and advertising and W. S. M. Mead, who succeeds Mr. Emise as manager of the New York and Metropolitan Agencies, will also have charge of the foreign department, with headquarters at 1751 Broadway, New York City.

—At the annual meeting of the stockholders of the K-R-I-T Motor Car Co. at Detroit, it was decided to add two more stories to the plant at the foot of Lieb street, increasing the capacity to 5,000 cars per year. Directors were elected as follows: W. L. Piggins, B. C. Laughlin, Kenneth Crittenden, William Van Sickle, L. C. Sherwood, J. W. Kanter and George G. Harris. The new officers are: President, W. L. Piggins; vice-president, Kenneth Crittenden; secretary and treasurer, B. C. Laughlin; manager of sales, J. E. Winney. The company will add to its line this year a surrey model for four passengers. The K-R-I-T Motor Sales Co. has been organized to handle cars of this make and will be located at No. 461 Woodward avenue, with Thomas C. Harris in charge.

The South and the Coast

PREPARING FOR ATLANTA'S FALL SPEEDWAY RACES —IMPROVING THE LOUISVILLE-NASHVILLE TURNPIKE—LOS ANGELES DEALERS ABANDON RACING—OREGON STATE A. A. MEETS TO-DAY

—The city of Harrisonburg, Va., has installed two motor cars in the headquarters of its water department.

—Walter E. Smith, Louisville agent for the Matheson car, has joined the salesforce of the Olds Motor Works.

—The Murray Motor Car Company has entered the Seattle field and is located at 1716-18 Broadway. This company has taken on the Hudson car and the Gabrowsky power wagon.

—Charles E. Miller & Bro. have secured the agency for the Owen in Washington, D. C., and vicinity and will be located on Fourteenth street, in the heart of the capital city's motor row.

—F. A. Mitchell, one of the veteran automobile men of Seattle, who has been away from that city for the past two years, has purchased the garage of the White Motor Company on Broadway.

—Edward E. Gerlinger has taken the agency in Portland, Ore., for the Stoddard-Dayton. The agency will cover the State of Oregon and will be known as the Stoddard-Dayton Automobile Company.

—Among the agencies for the Owen closed during the past ten days are: J. P. Burrus, McKinney, Tex.; John Ackard & Sons, Colby, Kan.; O. J. Merrill, Edgar, Nebr.; Bert Gilhousen, Los Angeles, Cal.

—The Standard Auto Equipment Corporation, of Richmond, Va., has been granted a charter by the Virginia Corporation Commission. The incorporators of the company are: B. C. Patte, president; C. Ridgeway Moore, vice-president, and George A. Perry, secretary and treasurer.

—Richmond, Va., is considering motorizing her fire department. A representative of the city has been away inspecting machines at various points and has returned much pleased with the demonstrations.

—After a stormy session, the Licensed Motor Car Dealers' Association of Los Angeles voted to take no further part in racing events of any kind, but will permit members of the association to enter races at their will.

—The Kentucky Automobile Company has secured a building adjoining its present location on Third avenue, south of Breckenridge street, and is moving its offices to that structure. The company is the agent for the Cadillac cars.

—Two Louisville automobile houses have exhibits at the Applachian Exposition at Knoxville, Tenn., September 12 to October 12. The Olds Motor Works and the Studebaker Automobile Company will show machines.

—One of the latest cars to enter the Baltimore field is the Everitt, the agency for which has been taken on by the Pullman Automobile Company, Inc., with office at 1117 Cathedral street and garage and repair shop at 1803 Lovegrove alley.

—Kentucky and Tennessee motorists and citizens living along the line of the old Louisville and Nashville turnpike are agitating the question of improvements for that important and historic highway. A meeting is to be held at or near Smith's Grove in the near future to discuss ways and means of procedure. The road in question received a good deal of undesirable advertising following the 1910 Glidden tour.

Seen in the Show Window

IN these days of stringent speed laws it is sometimes convenient for the autoist to know exactly how fast he is driving, how long he has been upon the road and how far he has traveled. In the Cleveland Speed Indicator (AQ), made by the company of the same name at 1806 Euclid avenue, Cleveland, O., he is provided with a device which tells not only the miles per hour, the trip hours and trip miles, but the season hours and the season miles. The running time record will be excellent evidence for every law-abiding motorist in the event of police interference, as the indicator shows at all times the number of miles and the running time. The instrument is kept in motion by a flexible shaft connection to the automobile wheel. The fastest moving part of the indicator revolves only 30 times for each mile.

A MAKER who regularly equips his cars with the Veeder Odometer (AR), made by the Veeder Mfg. Co., 22 Sargeant street, Hartford, Conn., gives evidence of a confidence in the reliability of his wares that should go far to convince a prospective customer of the honesty of his claims, for this little instrument will act as a tell-tale should he overrate the battery mileage, gasoline and oil consumption, tire mileage or the longevity of the various parts. The dashboard type of odometer has two registers—a total and a trip. The trip can be set back to zero at will; the total cannot be set back. The type of odometer which is designed for attachment to the front wheel is also shown; it is regularly supplied for use on the left wheel, but can, when so ordered, be supplied for the right front wheel.

ROUGH roads deliver hammer blows to the wheels, tires and mechanism of an automobile that would materially shorten their life were it not for the springs. But to successfully cope with such conditions the springs must be necessarily so stiff-acting that riding in a car thus equipped is tiresome in the extreme. The Koehler Cantilever Spring (AS), made by the Universal Auto Spring Company, 8500 Florissant avenue, St. Louis, Mo., is designed to withstand heavy shocks and yet be sufficiently "soft" in action to insure comfortable riding. The company claims that with these springs the use of solid tires on pleasure cars is rendered quite possible; shocks on the engine and the road wheels are minimized, and the life of pneumatic tires lengthened.

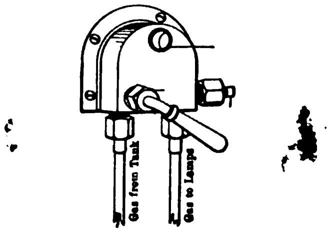
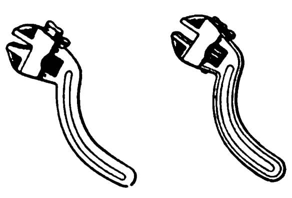
AT



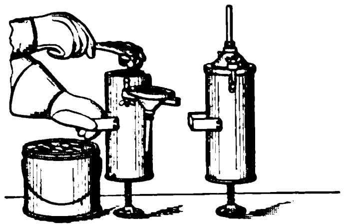
AT—Inst Lighter saves the autoist money

AU



AU—B. & S. Wrenches for tight places

AV



AV—The Little Giant Grease and Oil Gun

WASTEFULNESS in the use of acetylene gas on automobiles costs considerable money in the aggregate. The trouble of lighting and relighting lamps with each succeeding stop when traveling at night usually induces the autoist to allow his lights to remain burning, regardless of the length of the stay. It is to remedy this very situation that the Inst Lighter (AT) has been perfected by the company of the same name at 53 East Main street, Columbus, O. By a turn of a handle and the push of a button the driver of a car, without leaving his seat, has instant control of the lighting and extinguishing of his head lamps. The lighter is installed on the dash and takes up but little room.

THE location of some of the nuts and pipes in the mechanism of an automobile makes them so difficult of access that in the event of their needing tightening the ordinary form of wrenches is found practically useless for the purpose. The Billings & Spencer Co., of Hartford, Conn., realizing the necessity of a new form of wrench to enable the motorist to reach the otherwise un-get-at-able nuts and pipes, has designed the B. & S. adjustable wrenches (AU) here shown. The curved handle enables one to get the jaws of the wrench onto a pipe or a nut that could not be reached with a straight-handled tool. These wrenches are made of drop forged steel and are fitted with a patent nut lock to prevent slipping.

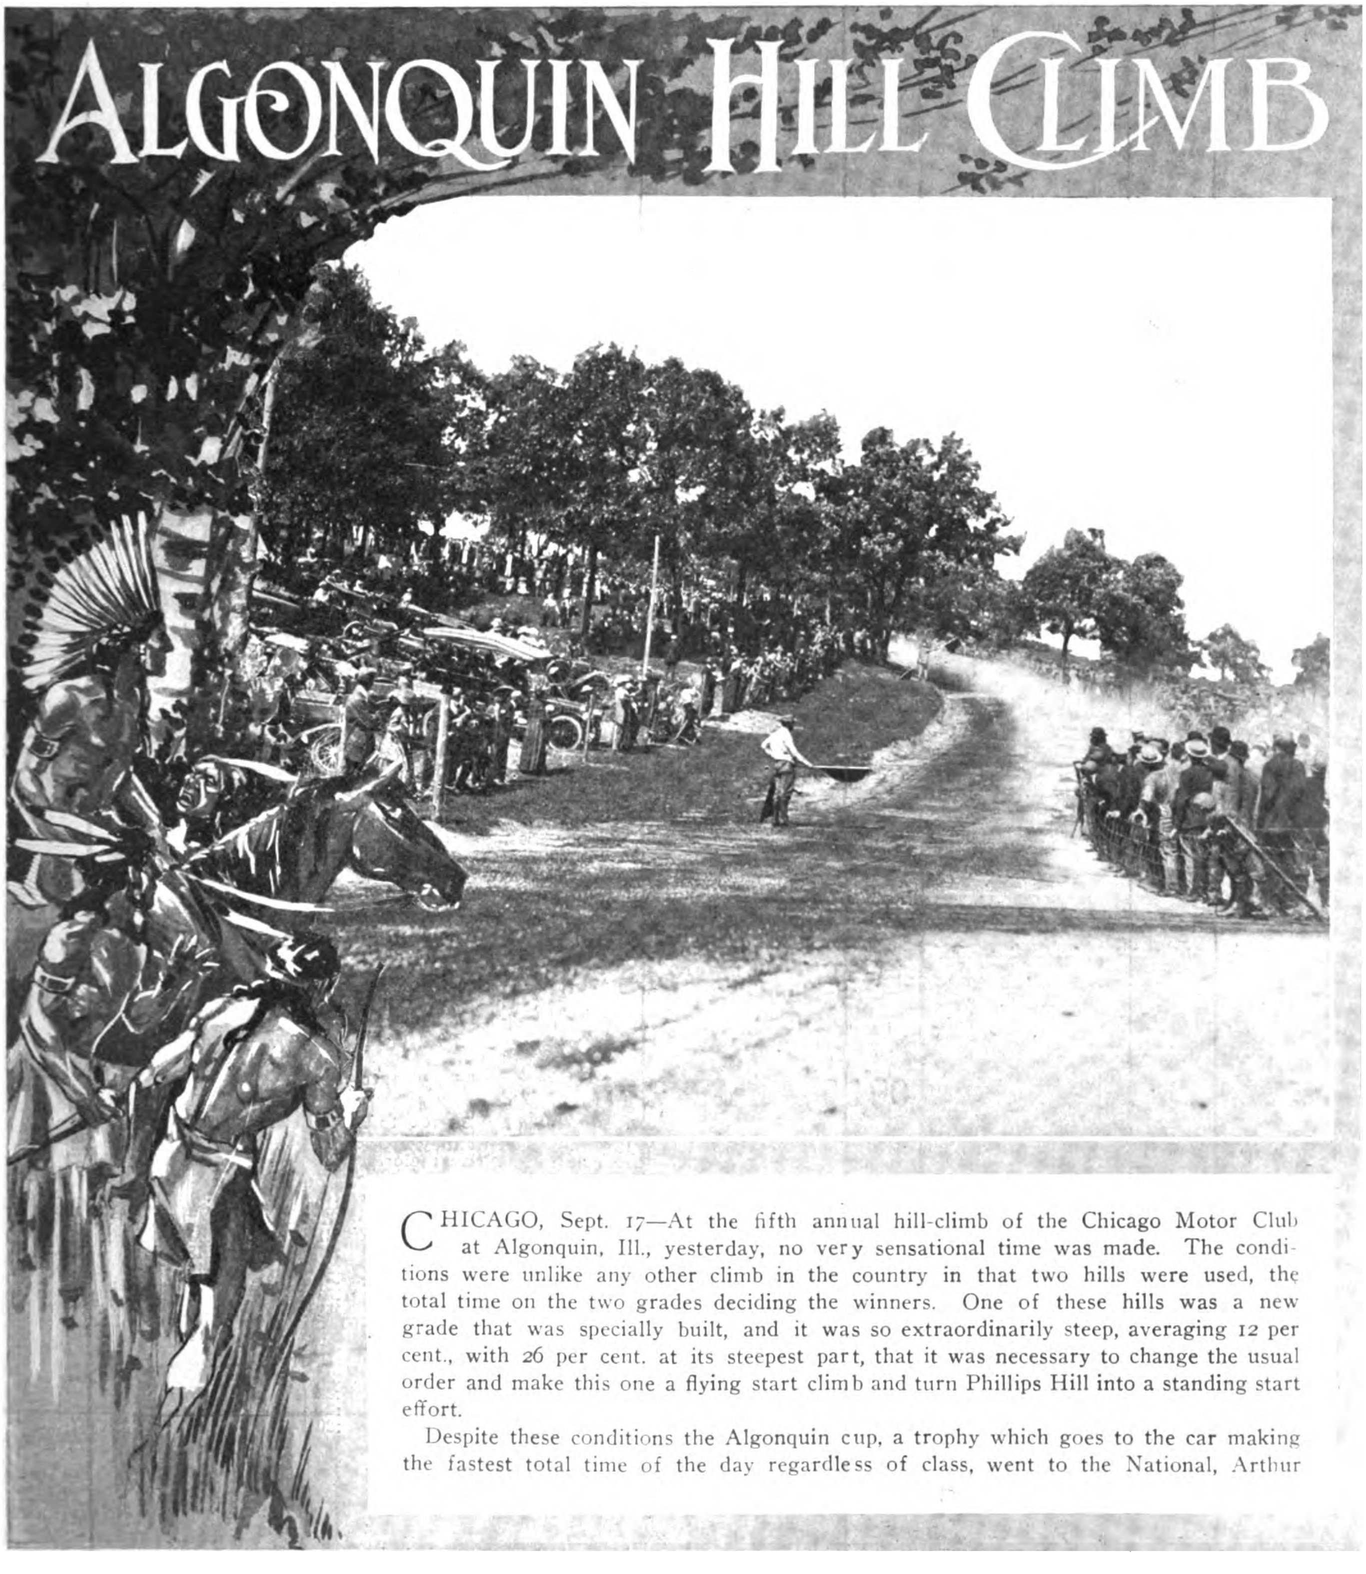
LUBRICATING gear cases and differentials is a nasty job under ordinary conditions. Greasy hands and gloves, soiled clothing and smudged features are the usual accompaniments of the process. In an effort to ameliorate these conditions the Neiman Machine Works, of Freeport, Ill., have designed and are marketing the Little Giant Grease and Oil Gun (AV). The device consists of a metal cylinder holding a quart of oil or 2 1-2 pounds of grease; a removable cover and spout, and a screw piston to quickly propel the lubricant to the point where it is needed. A side handle makes the gun easy to carry.

MAKERS of lubricants, cleaning compounds and other materials that must be sealed in cans will find something to interest them in the announcement that L. & J. A. Steward, of Rutland, Vt., have perfected a machine for sealing open top cans after being filled. The filled cans, with covers laid on top, are placed on a feed belt, which carries them to a header where the covers are forced on and fastened. From there the cans are taken to the dial plate, where each can, remaining stationary while the head revolves, is automatically sealed.

Vol. XXIII New York—Thursday, September 22, 1910—Chicago No. 1

THE AUTOMOBILE

ALGONQUIN HILL CLIMB



CHICAGO, Sept. 17—At the fifth annual hill-climb of the Chicago Motor Club at Algonquin, Ill., yesterday, no very sensational time was made. The conditions were unlike any other climb in the country in that two hills were used, the total time on the two grades deciding the winners. One of these hills was a new grade that was specially built, and it was so extraordinarily steep, averaging 12 per cent., with 26 per cent. at its steepest part, that it was necessary to change the usual order and make this one a flying start climb and turn Phillips Hill into a standing start effort.

Despite these conditions the Algonquin cup, a trophy which goes to the car making the fastest total time of the day regardless of class, went to the National, Arthur

Greiner driver, with an average of 42 miles an hour for the two hills. On the new hill, the National went up to 38.8 miles an hour to the 1,000 feet, while on the half-mile Phillips Hill its time was :39 4-5. A 45-horsepower Benz, driven by Hearne, climbed Algonquin Hill fastest, its :17 2-5 being a shade better than the National's :17 4-5. On Phillips Hill, though, the National did :39 4-5 twice.

33—Midland	Ireland	:20 4-5	:50 3-5	1:11 3-5

The Falcar, Velie, Staver, Jackson, Parry and Moon all won is their respective classes. The formula used consisted of multiplying the cylinder capacity by the time as expressed in seconds and dividing that result by the weight of the car. Under this figuring the winners were the Brush, Cartercar, Staver, Marion and National. The Staver made the best percentage of the lot, its figures being 7.41.

Records Fall at Syracuse

ONE AND FIVE-MILE MARKS FOR CIRCULAR TRACKS REDUCED SMARTLY—NATIONALS WIN THREE RACES AND FORD TAKES ONE

SYRACUSE, N. Y., Sept. 17—Before a crowd estimated at 80,000 persons, the automobiles had a memorable inning at the finish of the State Fair this afternoon. The program consisted of two ten-mile dashes under piston displacement classification, both of which proved victories for Nationals, but the winners turning up in different cars; a five-mile race under similar classification, which was won by an S. P. O. car; a five-mile special for residents of Syracuse, which also went to a National car; a five and a ten mile free-for-all; a ten-mile free-for-all handicap, won by a Ford, which defeated a National which won one of the other events and the S. P. O., and one and five-mile time trials against the world's mile circular track records of 49.29 and 4:24.20 respectively, both of which were reduced by a Fiat. The marks set were 48.92 and 4:11.90. Automatic electric timing devices were used and a claim for official recognition of the marks will be made.

The racing was full of action even if sturdy competition was lacking in the free-for-all races. The feature of the day's racing was the showing of the Nationals and the Ford entry. It was reported that a Simplex 90 which had been entered in several of the events broke a camshaft just before the call to the post. This robbed the free-for-alls of much of the contest element.

Aside from the attractions of the card, the crowd enjoyed an address of Colonel Roosevelt which was carded to take place before the races. The speech was to have been 50 minutes long, but was shortened to half an hour by the anxiety of the crowd to see the racing machines.

The racing officials were: Honorary referees: Colonel Roosevelt and Lieutenant-Governor Horace White. Referee, A. R. Pardington. Announcer, Peter Prunty. Judges: E. L. Broadwell, Thomas J. Wetzell, Alexander T. Brown, Ray B. Smith and H. W. Smith. Clerk of the Course, Nelson C. Hyde. Timers, M. C. Kleck, E. B. Van Wagner, N. H. Oliver, W. C. Poertner, C. M. Hall and Willett L. Brown. Technical Committee: Alden L. McMurtry, John Wilkinson and S. G. Averill.

The summaries:

No. Car	Driver	Time
Five miles, cars under 300 cubic inches—		
1—S. P. O.	John Juhasz	5:28.92
2—Mercer	E. H. Sherwood	
3—Maxwell	Ellery Wright	
Ten miles, cars of 301 to 450 cubic inches—		
1—National	W. King Smith	10:10.76
2—National	Louis Disbrow	
3—Velie	Roy Robbins	
Five miles, free-for-all—		
1—Fiat	Ralph De Palma	4:24.15
2—Ford	Frank Kulick	
3—Knox	M. Lee Brock	
Five miles, special for residents of Syracuse—		
1—National	Charles Rollins	12:49.60
2—Simplex	Roy Hawkins	
3—National	Richard Gleason	
One mile time trials (track record 52 3-5 seconds)—		
1—Fiat	Ralph De Palma	0:49.13

Louisville Club's Run Makes Start

LOUISVILLE, KY., Sept. 20—With less than half the number of cars entered that participated in the 1909 run, the annual Reliability and Economy Contest of the Louisville Automobile Club started this morning. The reason for the small entry list is the fact that local dealers have not yet received their 1911 models to as great an extent as they had last year at the corresponding date.

The run will be 433 miles. The route to-day is to Harrodsburg, with the Lincoln Farm as noon control, a total of 142 miles. To-morrow's route is to Winchester, 149 miles, and the third and final day will be spent in running 142 miles back to Louisville.

The tour is divided into two general divisions: one for reliability and the other for economy. In the economy division, reliability will also count as a factor in winning, but the consumption of oil and gasoline will be taken into consideration.

The cars, entrants and drivers in the reliability division follow:

No.	Car	Entrant	Driver
2	Cadillac "30"	Ira S. Barnett	W. McDonald
3	Oldsmobile Limited	Olds Motor Works	F. W. Tuttle
4	Oldsmobile Special	Olds Motor Works	Harry Smith
5	Hudson	A. L. McCormick	
6	Regal	Atlas Machine Company	W. H. Emler
8	Cadillac "30"	Ira S. Barnett	George Younger
		ECONOMY DIVISION	
1	Cadillac "30"	Ira S. Barnett	
8	Cole "30"	A. L. Martin	

The official cars include the following:

Car	Entrant	Use
Cole "30"	A. L. Martin	Press
Packard	Lee Miles	Pacemaker
Oldsmobile	Olds Motor Works	Confetti

Richmond Endurance Attracts Entries

WASHINGTON, D. C., Sept. 18—Ten cars have been entered to date in the five-day endurance run to Richmond and return under the auspices of the Washington *Post*. The entries are three Buicks, two Oldsmobiles, two Washingtons, two Maxwells and a Columbia. The dates selected are October 14-18, giving four running days with a Sunday layover in Richmond. The distance is 475 miles.

The route is via Leesburg, Winchester, Staunton, Charlottesville, Scottsville, Columbia, Richmond, Louisa, Orange, Locust Dale, Culpeper, Warrenton. The night stops will be Staunton, Richmond and Warrenton.

The probabilities are that 25 cars will compete. In addition to a trophy for each division, there will be a sweepstakes prize.

Southern Race Meet a Success

COLUMBIA, S. C., Sept. 17—The two-day race meeting staged at the Fair Grounds here yesterday and to-day proved a big success from every viewpoint. There was one race yesterday, a 100-mile affair with six entries, which was won by a Buick by two minutes in 1:58.5. To-day's card consisted of three events, one each at one, five and fifty miles. The Ford entry won the mile race in 1:09, the Pullman took the five-mile event in 5:51 3-5 and the fifty-mile trial was annexed by the Ford in 55:53.

The long races were well contested, the win of the Buick having been accomplished through its good fortune in avoiding mechanical and tire trouble at all stages as well as to its speed. The Ford car won rather easily after a series of early brushes which accomplished the downfall of several of the heavier cars.

Engineering Section

DEVOTED TO THE DISCUSSION OF ENGINEERING PHASES OF AUTOMOBILING, INCLUDING DESIGNING AND CONSTRUCTION FEATURES OF PRODUCTS, AND INFORMATION TO AUTOISTS

GOOD MATERIALS MUST BE CAREFULLY STORED AND PREVENTED FROM BEING MIXED—DIAMOND CHAIN METHOD

MAKING a mistake when the proceeds of a day's work as represented in money are being counted, may result in the loss of a few dollars, which in the long run is readily charged off to profit and loss, and the amount of the damage resulting may be directly measured by the magnitude of the error made in the counting. But if in a plant where automobiles are being made a large variety of materials are found to be necessary for the best result, and the materials are not so separately stored that error creeps in, the opportunity for putting the wrong material into a part requiring a better grade of the same will be ever present, and the extent of the loss involved in the event of such an occurrence may be far beyond that as represented in the error of count as before mentioned.

It is out of the question to expect that the average workman will be able to tell a bar of chrome nickel steel from a Bessemer bar, if the two bars are of like diameter and stored in the same rack. Of course, the machinist who has to do the work would know the difference due to the cutting hardness of the one as compared with the other, but even his method of measuring would fall short of the requirement were a comparison to be made between a Bessemer bar and a piece of acid open-hearth steel of the same carbon content.

It would not be out of place to expect excellent results from crankshafts made of acid open-hearth steel, but should the materials be stored promiscuously, and the workman, through some inadvertence, were to use the Bessemer steel in the forging of crankshafts, the cost of this carelessness would be measured by (a) the cost of the Bessemer steel wasted, (b) the cost of forging the same, (c) the cost of machining work done upon it, (d) the cost of bluing, scraping and fitting, (e) the cost of the interruption of service and of the crankshaft brakes, (f) the cost of laying up the car while a new crankshaft is being made and put into position, (g) the extra cost involved in making the new crankshaft, (h) the cost of besmirching the reputation of the maker.

There are now so many sizes and grades of steel used in the better class of automobile work that it is no longer possible for any store-keeper, no matter how skilled he may be, to keep track of the respective grades and to be able to put his hands upon them promptly and on a sufficiently definite basis to satisfy the exacting demand. The illustration, as here afforded, is of the method in vogue in the plant of the Diamond Chain & Manufacturing Company, of Indianapolis, Ind. The racks as shown are placed on the ground floor of a substantial fire-proof building; they are of structural steel and the respective compartments are in point of dimensions fixed in the light of the quantity of each grade of steel carried in stock. In addition to having the respective grades of steel stored in separate compartments, it is the practice at this plant to paint the ends of the bars, using distinctive colors for the respective grades of the materials carried in stock. The question of just which color to adopt for a given grade of steel is a matter of no moment, provided this color is definitely assigned once and for all, and is never used for any other such purpose.

This plan works out to advantage in other ways besides making mistakes impossible. Workmen learn to do things systematically, if the system is plain and attracts their notice, and it has been found in this case that the men who do the work are really fond of daubing paint over the ends of the bars, the reason for which lies in the fact that it is easier work to paint bars than it is to lift steel. Evidently this painting project appeals to the artistic side of the workman, and it is one of the situations that illustrates perfectly the exercise of business acumen involved in a system that caters to the vagaries of men.

1911 Laboratory Prospects

SECOND INSTALLMENT, DEALING WITH THE LABORATORY SUBJECT AS IT IS HANDLED BY MAKERS OF AUTOMOBILES

AUTOMOBILE users' interest in the laboratory question ceases when the road performance of cars is analyzed. It is worth something to the user to know the limitations of automobiles, and to be able to foresee the limit of profitable performance. There are a great many things that it is possible to do with automobiles, but the question is, will it pay? In other words, what are the commercial limitations of the automobile? It seems to be convenient to overlook the fact that it is a commercial enterprise that is represented when a banker is taken from his residence to his place of business, or when the banker's wife is carried in comfort and in style when on shopping bent. It is even a commercial enterprise when the banker's daughter is transferred from her place of abode to the music master, and it is not far-fetched to hold that there is a certain commercial phase represented in the process by which the banker's son invests in a racing automobile and traverses a whole State, touching the high spots only.

Just what is the commercial aspect represented in the mad prank of the banker's son? Does he not represent the only laboratory that was in existence during the earlier life of the automobile art? Who is it of the pioneers of the automobile industry whose memory falls short just before account is taken of the speed-mad laboratories that paid good money for his make of automobile and served in the capacity of the dog on whom the lack of quality of the product was tried out with a view to finding out whether or not it was any good.

That these brave and enthusiastic autoists accomplished all that could have been mastered even in a laboratory at the time is a point that will be well appreciated by all who take into account the fact that in addition to locating the weakness in cars, there was the further advantage of conducting the tests under severe road conditions. Now that the art has progressed, and the automobile has lost much of its glamour, most citizens are willing to decry speeding, and they discountenance recklessness as it is practised by the banker's son who lacks neither money nor red blood.

It is fitting that the users of automobiles shall conduct their experiments in club laboratories rather than to indulge in

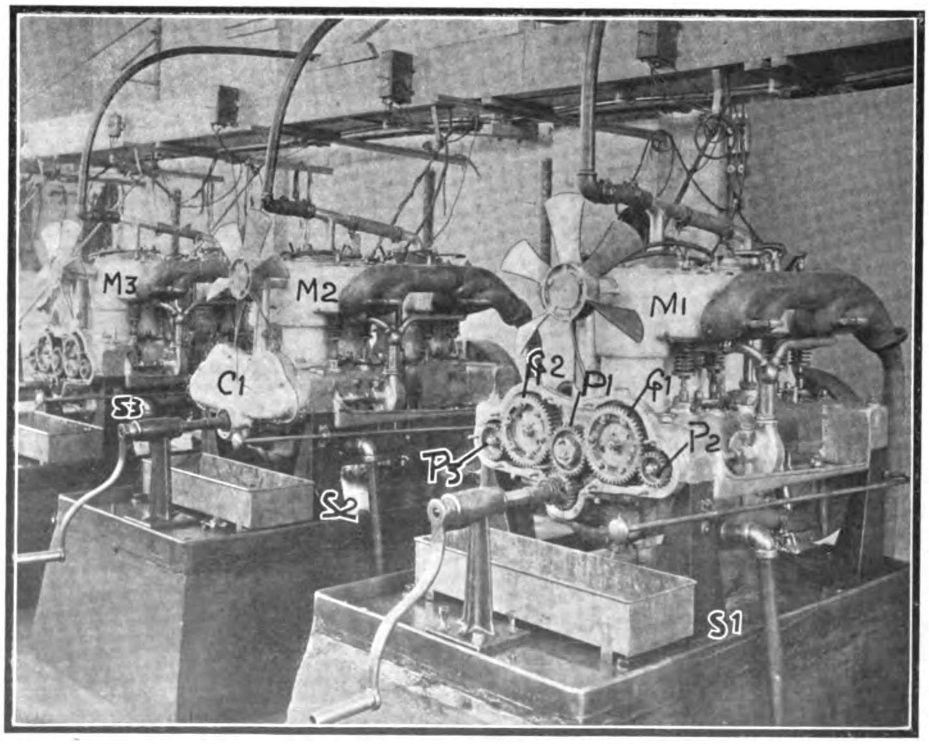

Fig. 16—Run-in test of completed motors at the Lozier plant, with means for loading and determining proper relations of parts

reckless driving on the road, and that the equipment shown as having been installed by the Automobile Club of America is representative of progress from the users' point of view may be taken for granted. The fact remains, notwithstanding anything that users may do along the line as here indicated, that tests should be made and laboratory investigations are better conducted before the cost of building the automobile is incurred. It is like locking the door after the horse is stolen, to avoid making tests during the construction period, only to do this testing work after the cars are built and sold.

The new idea, if indications count, has for its basis a full and proper investigation along laboratory lines during the constructive period of cars and a more or less careful review of the situation on the part of owners after the cars are made. There is one further point of interest, however, that has not been touched upon heretofore, *i. e.*, the Automobile Club of America and kindred establishments, to the extent that they indulge in laboratory work, offer excellent facilities to autoists of the class whose minds run to invention. If a member of the club, as a result of his experience, finds himself in the predicament of having an idea that refuses to down, he may go to the club laboratory and have the same translated into the form of a device or mechanism, and then he may have the plan put to practical test, and if it proves to be efficacious in the filling of a useful niche, all that remains is to add the commercial touches. In this way the experience of capable autoists is given to the world, and it is only in this way that matters such as this can be handled.

In the shops where automobiles and accessories are made commercial success depends upon concentration. The representatives of these plants have no time to devote to incidental experimenting; their success lies in confining their efforts to the undertakings for which the plants are instituted. Of course, there is a bond of sympathy between the man who in using a car discovers something that will benefit the art and the man who in making the car finds out that the degree of perfection he aims at is retarded for lack of something. The club laboratory should serve as the instrument by which a connection can be made between the user who finds out something and the maker who has a place to put it.

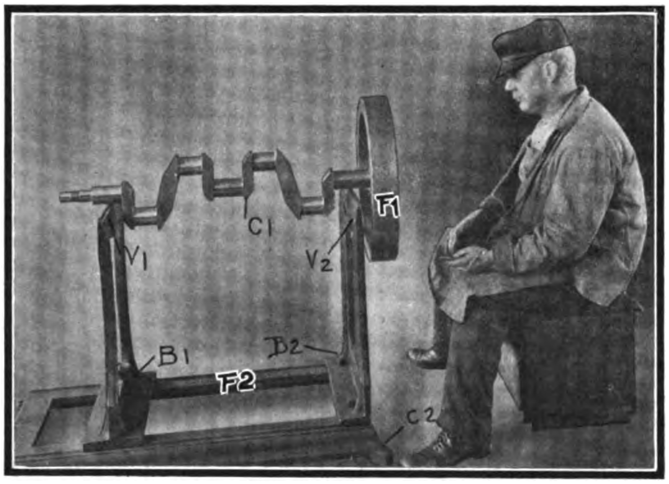

Fig. 12—Method of determining the static balance of a crankshaft after the flywheel is pressed on

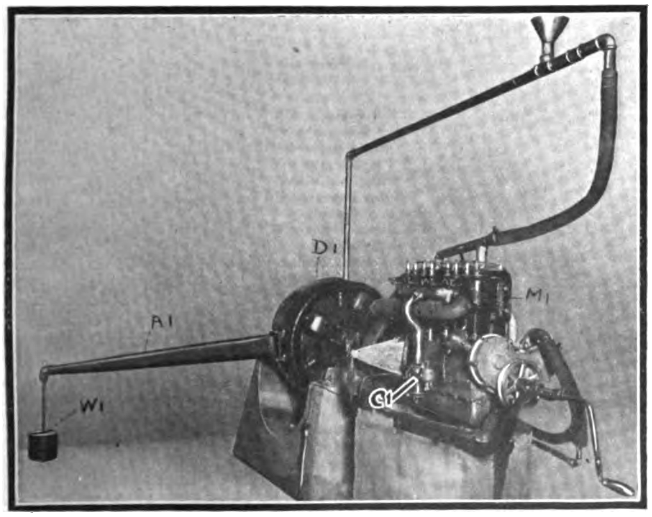

Fig. 15—Electro-dynamometer as used in the Inter-State plant at Muncie, Ind.

Fig. 9—Depicting the method in vogue in the Packard plant for inspecting valves

Some of the Methods in Vogue in the Shops

In some plants instead of having a separate laboratory devoted to testing and the various investigations the instruments of precision and equipment used for testing are distributed about and utilized in an incidental way. In other establishments the laboratory equipment is separated from the manufacturing plant, and the various tests and investigations necessary in the industry are conducted by a corps of men who do nothing else. It will not be the purpose here to attempt to determine as to the respective advantage of each of the methods; it is even possible to foresee that it makes very little difference whether a test is conducted in one room or another so long as the facts are brought out and they are utilized to good advantage. Fig. 9, for illustration, shows how valves are tested for accuracy in the Packard plant, in which L1 is the bed of a small lathe, H1 is the headstock, and T1 is the tailstock. Holders H2 and H3 with adjustments take the V's, V1 and V2, into which the stem S1 of the valve is placed, and the accuracy of the beveled seat B1 is determined by means of the extensometer E1. The work is quickly done, and an error of 0.0002 is readily detected, although the workman is enabled to reach a speed of from 20 to 30 valves per minute. There is no reason why this operation should be conducted in a separate laboratory, and it is even possible to foresee advantage in having the inspection performed during manufacture and as one of the regular operations. The moral effect of letting the machinist see that he must do accurate work, or have it thrown back on his hands, is worth more than can be estimated readily. The workman is most impressed by things that he can see and understand.

In the same plant the motor crankboxes and the transmission gear cases are machined in the regular way, and it is to be presumed that the jigs and fixtures utilized will influence for rapid and accurate work. Notwithstanding the excellence of the facilities afforded, it is deemed fitting to have each unit set up on a face plate and measured by a man skilled in this class of work. Referring to Fig. 10, F1 is the face plate, C1 is the lower half of the crankcase, C2 is the upper half of the same. The two members are bolted together after they are machined and are rested upon legs L1 and L2 at one end, with a screw jack S1

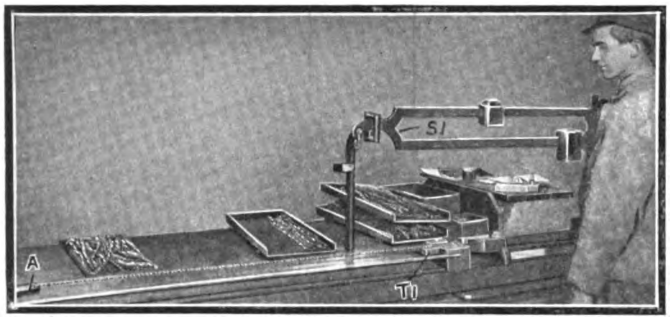

Fig. 14—Testing completed chains in the plant of the Diamond Chain and Manufacturing Company

placed to serve as the third support. The castings are provided with accommodation pieces which are milled off to a fixed distance from the flange faces so that when the legs L1 and L2, which are of a fixed length, are set up in position and the crankcase is rested thereon, the operator using a face gauge F2 fitted with an extensometer E1 has at his disposal a quick and accurate means of checking the work. He is enabled to observe with certainty the limits of tolerance maintained by the workman, and he can do this checking work in the shop alongside of the men who do the machining just as well as it may be done in a separate department devoted to inspection undertakings.

Illustrative of an important phase of constructive investigation work in the shop, reference may be had to Fig. 11, which was taken in the Packard plant, showing the face plate F1, with a crankshaft C1 and V-blocks V1 and V2 with instruments at hand for determining the accuracy of the work. The extensometer E1 is employed to determine if the main bearings are in alignment; it also tells if the centers C2 and C3 are identical as to axis. The fixed gauge G1 is used to size the holes H1, of which there are six, and the micrometer M1 is available for measuring the diameters of the pins, which measurements are taken at both ends, and at 90 degrees, it being the purpose to determine if the pins and bearings are round or elliptical, parallel or conical. The first requisite in the conduct of work of this character is a surface plate that is surfaced to great accuracy and so designed that it will not distort under temperature-changing conditions, to which must be added fixed gauges, extensometers and micrometers of known excellence, all of which in the hands of a skilled inspector.

As a further illustration of the excellence of the incidental method of checking the work during the process of manufacture reference may be had to Fig. 12. Here the crankshaft C1 with its flywheel F1 is mounted on V's V1 and V2, the latter being formed at the upper extremities of a pair of castings which have faced-off bases B1 and B2 designed to rest upon a cast-iron foundation F2, which is also machined with great accuracy, and is provided with crow feet C2, of which there are four with leveling screws attached, thus permitting the workman to level the V's, and after setting the crankcase in place and imparting angular motion thereto, it is allowed to some to rest unhampered, and the operator merely observes if the crankshaft with the flywheel in place is in a true state of static balance.

It is not the purpose of this test to arrive at an understanding of the kinetic conditions of the crankshaft and flywheel. This phase of the problem is taken care of during the designing process; kinetic balance is a mathematical matter to be disposed of, and since the design is symmetrical if the crankshaft and flywheel are machined to drawing size, the static balancing method is a very simple one by means of which inaccuracies in the manufacturing process are readily detected. This is another case of checking as incidental to the manufacture process, and there is no reason why this work should not be done in the very room where the parts are brought together and assembled.

Testing work is not necessarily confined to the processes by which inaccuracies of one or two ten-thousandths of an inch are determined; it is just as necessary to find out, for illustration, if the radiators are tight. Fig. 13 shows how this is done in many of the plants (this particular illustration being taken from the Packard), utilizing a compressed-air tank T1, fitted with a gauge G1, and a safety valve S1 with a pipe leading from the tank along the side wall to a point adjacent to the testing tanks. A length of hose H1 leads to each testing tank and is connected to the radiator R1 to be tested, the latter being submerged in water in the manner as shown, the tanks T2 being deep enough so that when the radiators are immersed therein they will be covered over by water. As the compressed air leads from the tank T1 to the piping and hose H1 to the radiator R1 if any of the air leaks out it will bubble up through the water and indicate the proximity of the fault in the radiator. The air pressure is high enough to develop weaknesses in the structure of the radiators, and it is a quick and efficacious way of locating any leaks that may obtain after the radiators are supposed to be finished. Each radiator bears the number of the workman who would be held responsible for faults, and his attention is directed to any of the faults of workmanship that may be properly charged to him. If the weaknesses developed are due to faulty material this fact is also arrived at, and it is in this way that perfection finally takes up its abode in an automobile. It is a clear case of the elimination of the weakling idea and of the fitting survival of the worthy thought.

Fig. 13—Testing radiators by compressed air to locate leaks and to prove mechanical strength

Checking up the work as it is represented by the component parts that go to complete a unit is only one phase of the great main situation. As the component parts are made and tested, if they are found to be accurate, the next step is by way of assembling the components into units. When these units are assembled they have to be tested also in order to ascertain whether or not they will work in harmony. Fig. 14 is a capable illustration of the idea to be conveyed. It was taken at the works of the Diamond Chain & Manufacturing Company, at Indianapolis, Ind., showing the final test to which chains are put after they are made but before they are packed ready for shipment. The test is made by fastening one end of the chain to an anchor A1, and the other end of the chain to a traveler T1, the latter being actuated by a lever under the control of the inspector, but the pull in pounds is measured on the beam of the scales S1. A certain number of the sprocket chains are tested to destruction in order to find out what the ultimate strength is, but all of the chains that are sent out to do service are tested to some percentage of the ultimate strength, the latter being some multiple of the safe working load. As a rule it is found that of the few chains that do show lack of ability the fault lies in a structural imperfection of the material in some one of the links. The inspection department is fitted out with the facilities by means of which the defective link is at once replaced by a good one and the chain is immediately thereafter retested and if it stands up to the retest it is passed into circulation. There is a certain deliberate accuracy attached to this process. It is quite as scientific as ingenuity is capable of inducing, and yet it has the speed, coupled with precision, that makes for commercial success.

While the opportunity affords it may not be out of place to enlarge somewhat upon the advantages that are inherent in the very process of testing, that instead of impeding progress offers a potential value, as in the case above cited. It is the experience of every shop man that the laboratory and methods of testing and checking to whatever extent they impede progress are unpopular. When a scheme invites accuracy and augments speed, its popularity is assured, and the results obtained under such conditions will be distinctly a commercial success.

Problem Is Intensified as It Leads Up the Line

It will be recognized that the practical inspection and test of the units and the further inspection of the incidental assemblages are all preliminary to the more complete investigation of the assemblies that go to make the completed car. Referring to Fig. 15, which is an electro-dynamometer D1 coupled to a motor M1, this may be taken as one of the units in a considerable testing plant that is designed with a view to testing every motor made with sufficient accuracy to assure the maker that its timing is on a proper basis and that its torquing ability under the several conditions of speed will be up to the standard set by the company for its product. In a test such as this the carbureter C1 is investigated to observe its range of performance. By calibrating the dynamometer and using the curve of calibration the laboratory expert is permitted to note at a glance for every speed within the working range of the motor whether or not the carbureter is delivering a capable mixture. The weight W1 on the end of the arm A1 that will just hold the arm horizontally at any given speed may be fixed by consulting the curve of calibration, and if the carbureter is capable the motor will furnish the necessary power to conform to the general demand as indicated by the curve of calibration. As the speed of the motor is increased in response to the will of the operator the weight W1 is changed accordingly, and the torquing curve of the motor being tested may be plotted in a few moments if the carbureter is working properly, the timing is right, ignition is up to a fitting standard and the conditions of lubrication are as they should be; but should the motor fall below the standard set the means at hand are such as to enable the operator to quickly investigate the situation and put his finger on the festered spot.

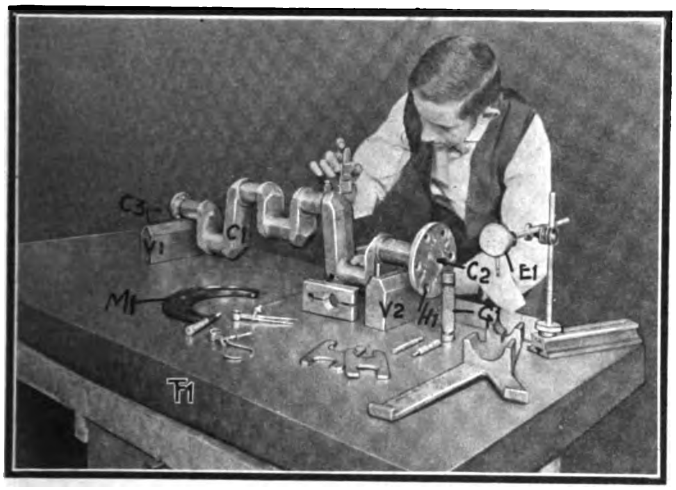

Fig. 11—Inspecting crankshafts in the Packard plant, using micrometers, fixed gauges, and extensometers under proper conditions

As a further advance embodying the laboratory idea with the practical situation, the makers of automobiles undertake to put the units through that which is known as a run-in test. Fig. 16 will suffice for the moment as indicative of the idea in which the motors M1, M2 and M3 are in a long row on test stands S1, S2 and S3, of which there are a sufficient number provided to test all the motors made as fast as they are produced. There is working room around each test stand so that the testers are enabled to inspect the motors under running conditions, finding out if all the joints are tight, and noting whether or not there is any noise or disalignment of relating parts. As the illustration shows, the cover C1 of the half-time gear housing is removed from two of the motors shown, disclosing the pinions P1 and the half-time gears G1 and G2, also the pinion P2 that drives the water pump and the pinion P3, which is placed to actuate the magneto. If this train of gears is not properly installed the tester will be able to note the fact; if there is any noise he will undertake to locate the cause thereof, and in fine the great value of the run-in test lies in the opportunity afforded for determining under working conditions just how good the performance is, and if a remedy becomes a necessity the reason for the same is not hard to find.

Caring for the Automobile Top

As an important feature of proper car equipment, the automobile top is deserving of a degree of attention commensurate with its relative value as a factor in automobile service. It is an expensive part of the car, and it is exposed to a particularly harsh form of service.

It is crushed together, and in this position made to serve as a receiver of highway dust and dirt, and during storms its extended surface is mercilessly assailed by the elements, so that, on the whole, unless given exceptional care and fortified with some preservative material designed to strengthen and enlarge its capacity for service, the days of its usefulness are destined to be few.

The directions for caring for the top are, in the main, simple and not many. Clean as often as possible of mud, road dust and dirt accumulations of every sort, all of which are injurious to the leather, rubber or other fabric composing the top. In case these accumulations have taken hold of the surface of the top so that a light dusting will not suffice to remove the matter, whip a bit of castile soap in some clean, tepid water to make a froth of suds, and wetting up a soft sponge in the water, go over the top until thoroughly cleansed.

Never let this dirt and fetid matter remain long upon the top. Such substances destroy the enamel of the leather or rubber and this gone it is a short shift to decay for the top. After sponging off the top always dry it off with a wash leather.

With leather and rubber tops upon which the enamel remains intact and vigorous, this bathing in water, smoothed out with a spray of castle soap, as often as the top becomes foul with the filth of the road will to no mean extent prolong the wear of the fabric.

For the rubber top with a worn, broken and fractured enamel, showing a generally service-stricken surface, a dressing of real worth may be prepared as follows: Liquid asphaltum, one part; unrefined castor oil, three parts. Confine in a close vessel and agitate until a complete unity of the ingredients is secured. Should the dressing lack a sufficiency of black, add a bit of drop black cut with turpentine to a paint consistency. This will also do for the leather top. The castor oil renders the rubber or leather soft and flexible and neutralizes the tendency of the asphaltum to become brittle.

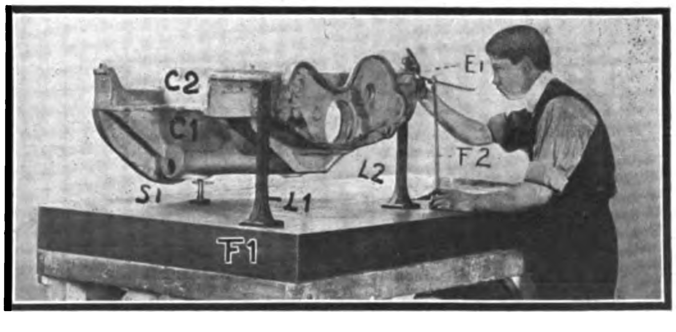

Fig. 10—Surface plate and gauge as used in the Packard plant in measuring up crankcases

Questions That Arise

CONCERNING THE POWER OF A MOTOR IN DIRECT PROPORTION TO SPEED; WORM-GEAR FORMULAE; CLEARANCE VOLUME IN CYLINDERS; TESTING PISTON DEFORMATION

[225]—Is the power obtainable from a motor in direct proportion to speed? If not, how does the power increase and when does it begin to recede as a result of the ills that creep in with increasing speed?

The following test is representative as a good average result, although the conditions indicated are considerably below the best expectation. In this chart (Fig. 1) the speed is plotted in revolutions per minute as ordinates and the horsepower output of the motor is given as abscissa. It will be observed that the line of increasing power is almost straight between 1,000 and 1,500 revolutions per minute. The peak of the curve takes place at 1,600 revolutions per minute, from which point on the power falls off at a rapid rate, it being substantially the same at 2,000 revolutions as it is at 1,000 revolutions per minute. For the purpose of showing that the power did not increase in direct proportion to speed at any time, it is only necessary to point out that at 1,000 revolutions per minute the power was 21 horsepower. The power should be 42 horsepower at a 50 per cent. increase in speed (1,500 revolutions per minute), but instead of 42 horsepower at this higher speed, the actual delivery was 40 horsepower.

[226]—What is the most simple formula of the worm gear, by means of which it will be possible to design worm gears for various purposes, including worm and sectors for steering equipment?

The following is conventional and sufficiently complete for the purposes named. It will be understood that a sector as used in steering gear is designed as a complete worm gear so that the formulæ of the worm gear applies perfectly. The illustration given is for the purpose of illuminating the text (Fig. 5).

CONVENTIONAL FORMULAE OF WORM GEARS USED IN DESIGNING

$$D = \frac{y\,P}{\pi} = 0.3183\,y\,P;$$

$$B = D + 0.6366\,P;$$

$$C = B + 2\,(N - N\cos A);$$

$$F = \frac{D + D'}{2};$$

$$M = \frac{D'}{2} + 0.368\,P;$$

$$N = \frac{D'}{2} + 0.3183\,P;$$

$$E = D' + 0.6366\,P;$$

$$B' = D' - 0.736\,P;$$

$$\text{Tang. } S = \frac{L}{\pi D};$$

$$L = P\,Z;$$

$$P = \frac{L}{Z};$$

$$Z = \frac{L}{P};$$

y = number of teeth in the worm wheel;
P = circular pitch;
S = lead angle in degrees;
tooth angle = 29 degrees.

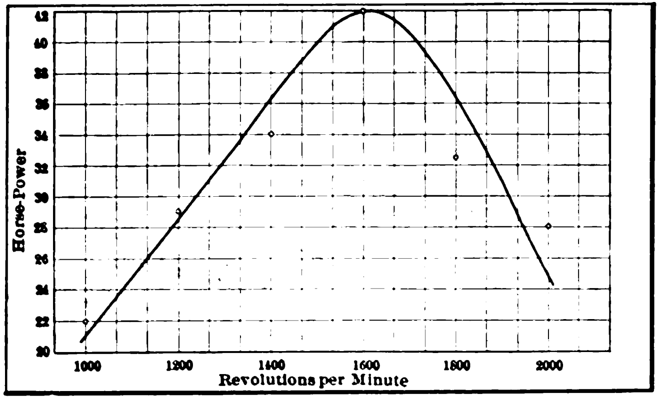

Fig. 1—Torque curve showing how the power increases with the speed up to a certain point and then falls away

[227]—Is the clearance volume exactly the same in each cylinder, considering motors turned out in regular practice?

There seems to be quite a little difference considering the tests available for inspection. With the difference as noted in the test here given, the performance of the motor appears to be up to every reasonable standard.

ACTUAL CLEARANCE VOLUMES

	CC	Cubic Inches	Per cent. of total volume
1	302.5	18.5	19.1
2	297.5	18.2	18.75
3	285.5	17.4	18.2
4	302.5	18.5	19.1
5	302.5	18.5	19.1
6	305.0	18.8	19.4

Piston displacement 78.8 cubic inches.

[228]—What is the practical performance of ordinary spark coils? Is there much lag?

The curve as given in Fig. 4 shows the performance of an ordinary spark coil; the lag is given as ordinates in degrees and the sparks per minute are given as abscissæ. Up to substantially 2,600 sparks per minute the plotting shows a straight line with a maximum lag of 20 deg.; after this the lag increases at an enormous rate, reaching nearly 50 deg. at 3,000 sparks per minute.

[229]—Is it possible to make pistons so light, that is to say, have the walls so thin that they will buckle in service?

It is suspected that this is a very ordinary difficulty and that it occurs in more cases than most autoists are cognizant of. The following test was made to ascertain the extent of piston deformation in one case; it is unimportant excepting to point out that piston deformation takes place if design is not proper:

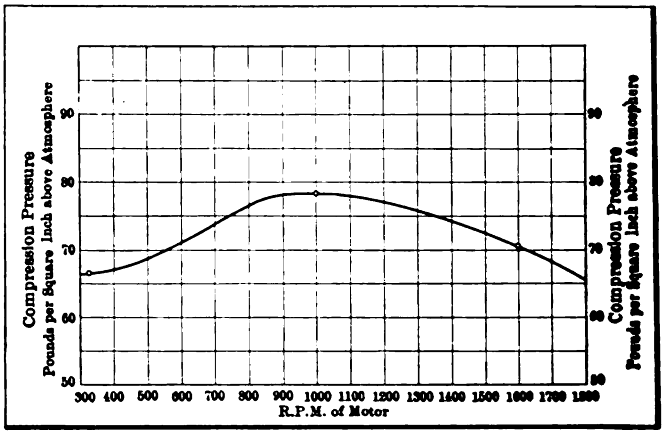

Fig. 2—Curve plotted to show how the compression changes as the speed of a motor is changed

Block Test to Determine Piston Deformation

Engine has been through testing block room and was taken out of stock. A marked heating effect was noticed, and after non-continuous running for a day the motor was torn down and the following measurements taken. Cylinder should be 3.625". Drawing calls for 3.622 straight except light chamfer near top bridge. Pistons are rough turned and filed, being in some cases touched up with emery cloth.

6	3.6253	3.6258	....	....

[230]—What is the usual arithmetical way of ascertaining percentage clearance in an internal combustion motor cylinder?

The first operation will be completed when the volume of clearance in cubic inches is known; the next step is to determine the volume in cubic inches of the space swept by the piston. With these data available the following will hold:

$$\text{Percentage clearance} = \frac{\text{Volume of clearance}}{\text{Volume of clearance} + \text{volume of piston displacement.}}$$

Volumes to be measured in cubic inches.

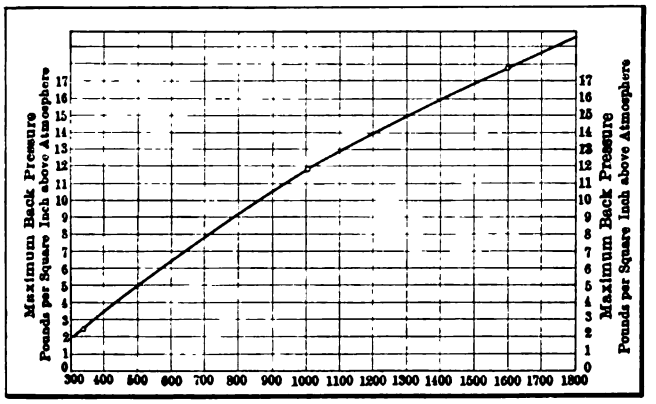

Fig. 3—Curve plotted to indicate the extent of back pressure of a muffler and the effect of increasing speed on the same

A numerical example is as follows:

Volume of clearance = 13.73 cubic inches.

Volume of piston displacement = 44.51 cubic inches.

$$\text{Percentage clearance} = \frac{13.73}{13.73 + 44.51} = 23.6.$$

[231]—Is the compression pressure constant or does it change with the speed of the motor?

In poorly designed motors the "cold" compression represents the highest point in the compression line. With such motors as the speed increases the compression decreases. This is due to wire drawing and other obstructive troubles to some extent and to back pressure on the exhaust side and inferior cooling for the rest. In fairly well-designed motors the compression increases with the speed of the motor for a part of the range, holds substantially constant over the working range and falls off slowly with increasing speed beyond this point. The curve, as given in Fig. 2, is representative of what might be termed good performance, in which the speed of the motor is represented as ordinates and the compression pressure is given in pounds per square inch above the atmosphere. An approximate tabulation of the results obtained in this case may be stated thus:

VARIATIONS IN COMPRESSION PRESSURE FOR VARIOUS SPEEDS

Revolutions per minute	Compression pressure in pounds per square inch above atmosphere
400	67.0
600	71.0
800	76.5
1000	78.5
1200	77.1
1400	74.3

The curve shows that the compression increased gradually up to about 800 revolutions per minute, remained almost constant between 800 and 1,300 revolutions per minute and fell away gradually as the speed increased up to 1,800 revolutions per minute. The running compression was almost as high as 1,800 revolutions per minute as it was cold.

[232]—Can mufflers be relied upon to eliminate the disagreeable sound without inducing back pressure?

As a rule, the reduction of sound from the exhaust of an internal combustion motor is at the expense of power. There are certain forms of mufflers that do better than others, but how much better can only be ascertained by proper tests. For the purpose of showing that back pressure does obtain and that it is in sufficient presence to merit serious consideration, a chart is offered (Fig. 3), a study of which will be enlightening. The speeds of the motor ranging between 300 and 1,800 revolutions per minute are charted as ordinates. The back pressure, which is given in turns in pounds per square inch above atmosphere, increases with speed as the curve shows and the variations in pressure are shown as abscissa. This chart says that for the particular muffler employed the back pressure increased with the speed as follows:

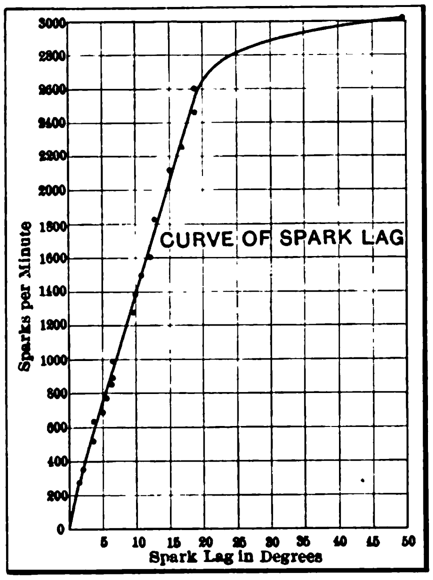

Fig. 4—Curve plotted to show the lag of spark of a spark coil as the speed of sparking is increased

APPROXIMATE INCREASE IN BACK PRESSURE WITH INCREASING SPEED

Revolutions per minute	Pounds per square inch above atmosphere
400	3.22
600	6.2
800	9.11
1000	11.95
1200	14.1
1400	16.0

Letters

COMMUNICATIONS FROM READERS MAINLY ALONG TECHNICAL LINES; LENGTHENING THE LIFE OF TIRES; CLAIMS OF THE KNIGHT PATENT; BRAKES SHOULD BE ADJUSTED WITH CAR LOADED; CARBURETER POPPING DUE TO POOR MIXTURE

Life of a Tire May Be Increased Considerably

Editor The Automobile:

[2,367]—I do not wish to complain, but it occurs to me that my tire bills are out of proportion, they being too high, and I fail to see how some of your good (?) advice can be taken excepting with a grain of salt. You say keep the tires fully inflated and they will last very much longer than otherwise, due to the fact that flexure will be reduced to a minimum. This is all very well, and there probably is something in it, but when I inflate the tires on the wheels of my car so that flexure is prevented it rides like a lumber wagon every time the speed is brought up to 40 or 50 miles per hour. Is it not a fact that the life of the rest of the automobile will be reduced to pulp if I inflate the tires so solidly that they will not cushion, since then the shock at high speed is so pronounced that it becomes uncomfortable to ride in the car?

New Rochelle, N. Y. C. M.

Take another grain of salt and think it over. Why should you drive your car so fast that you not only disrupt the speed limit but reduce the automobile to pulp as well? Perhaps your pocket book is perfectly capable of standing the strain even if the tires will not. There is a legitimate expectation from every make of automobile. You persist in passing beyond that point and prefer to ruin the tires of the automobile in order that you can indulge in your mad desire to wipe out the scenery, whereas were you to blindfold yourself you would not be bothered by scenic considerations, and with the speed reduced to a proper level the car would perform comfortably, the tires would last for a long time, and the cost would be low enough to permit an ordinary millionaire to pay the bill. Running on partially inflated tires results in all sorts of penalties, one of which is here illustrated. (Fig. 1.) In this case the tire was so soft that it picked up a railroad spike.

Yoke Type of Universal Joint

Editor The Automobile:

[2,368]—I have ball and socket joints on the steering rods of my car and it is my belief that they are not as good as if the bearings were long as in the usual form of bearing; since the action has to be universal, how must the joints be made?

W. W. Crandall.

New York City.

The idea can better be illustrated than described. Fig. 2 will suffice for the purpose.

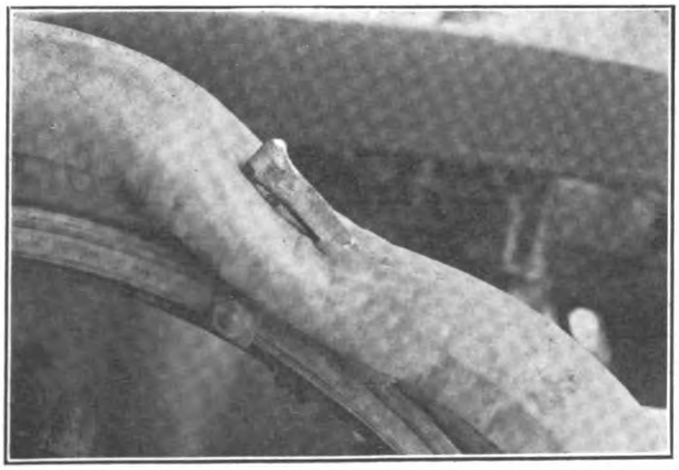

Fig. 1—Running on a soft tire—picked up a railroad spike

Sawdust May Be Put to Good Account

Editor The Automobile:

[2,369]—Is there anything that will effectually remove grease and grit from the hands after working with machinery? G. B.

Chihuahua, Mexico.

Take a quantity of sawdust, wet it with gasoline, add soap and use it for the purpose.

Letters Patent of the U. S. Issued to Knight

Editor The Automobile:

[2,370]—In The Automobile of Sept. 8 it was stated that the Knight patent has been issued; what is its principal claim?

Chicago, Ill. C. L. G.

The Knight patent was issued on Aug. 23, to Chas. Y. Knight, of Oak Park, Ill., the number of which is 968,166; a one-half interest in this patent is assigned to Lyman Bernard Kilbourne; the present control of the patent, according to advices, is vested in Knight & Kilbourne, of Chicago, Ill. The original application for the patent was made April 4, 1904. There are 28 claims; they are broad and sweeping; the "combination" claim is as follows: 28.—"In an internal combustion engine the combination of a fixed cylinder having intake and exhaust port, a cylindrical head projecting into said cylinder and spaced from the walls thereof and forming an annular space therewith, two concentric cylindrical elements telescoped with said cylinder over said head, around the combustion space of the engine, reciprocally in said annular space, the inner one of said elements having ports adapted to communicate with the said intake and exhaust ports and engaging the exterior of said head for controlling said ports therein and the outer one of said elements engaging the interior face of the fixed cylinder for controlling the said ports therein, a working piston reciprocating axillary with relation to said elements and surrounded by the inner one thereof, speed reducing means positively connecting the piston with said elements for reciprocating them with relation to the said head and fixed cylinder, and means for firing a charge in the explosion space." (See Figs. 3 and 4.)

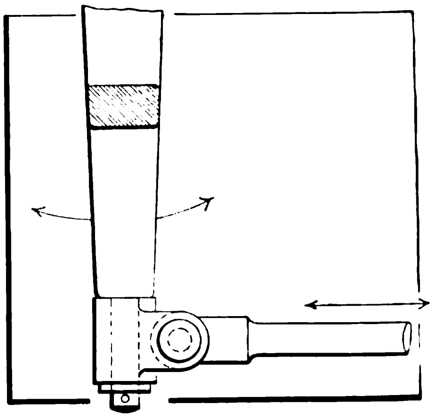

Fig. 2—Idea of a lever and rod with a universal joint connection, designed to supplant the usual ball and socket joint

See Page 287, The Automobile of August 18th

Editor The Automobile:

[2,371]—I was much interested in reading in your last issue your article giving the decision on the Selden patent.

For the information of myself and a great many other automobile owners, will you kindly give us the information as to when this patent expires, and if owners of unlicensed cars are in any way liable under such patent. M.

New York City.

The decree handed down by U. S. Circuit Judge Hough on

July 19 was given in full in The Automobile on page 106, issue of July 21. This decree was put into force by the action of the same judge, a memorandum of which was printed on page 287 of The Automobile of August 18. According to the information afforded, letters patent of the United States were issued to George B. Selden on November 5, 1895, No. 549.160, for improvements in road engines. The patent expires in 16 years from the date of issue. The Automobile, realizing the great importance of this patent, and having in mind the possibility of a new lease of life of the same, went into the matter at some length, even to the extent of consulting with legal talent, and as a result of this effort it was concluded that a reissue is not impossible. Should there be a reissue, it will be for 16 years.

Emergency Brakes of No Value Whatever

Editor The Automobile:

[2,372]—The puzzle that I have to solve has been with me for some time and I have tried to have it straightened out several times. Up to the present I have expended $70 without any good result, and a friend of mine who takes The Automobile states that you will solve my problem promptly and without any payment at all. The difficulty is this: When I tighten up the emergency brakes just as tight as they can be without dragging they seem to work, but when I go out on the road with the car I soon realize that the brakes are not working. I am sure that they work when I tighten them up and the question is: What is it that creeps in after I take the car out on the road? The car is a five-passenger light touring body and it gives good satisfaction excepting that it annoys me to think that I have no emergency brakes to fall back upon in a pinch. J. K.

Yonkers, N. Y.

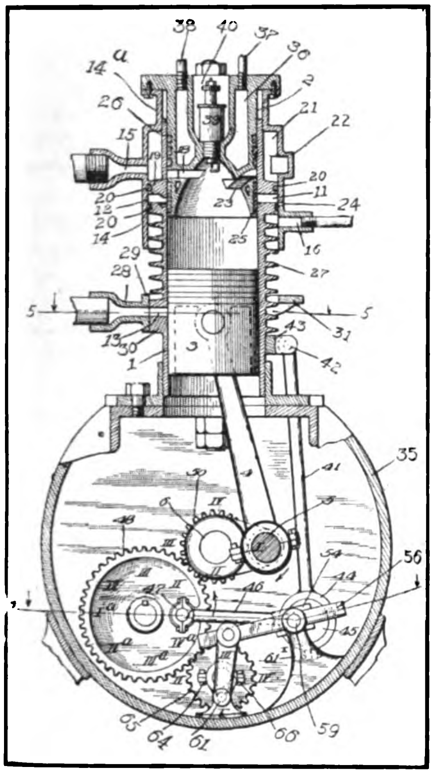

Fig. 3—Knight motor as shown in the original Patent Office drawing

The reason why the brakes do not work after the car is taken out on the road is that the adjustment is made when the tonneau is empty. The distance between the center of the rear axle and the point of fastening of the brakeshaft is too short. Tighten the brakes up so that they drag a little when the tonneau is empty and they will be free when the same is loaded down; another way is to adjust the brakes with the passengers in the tonneau. The real remedy lies in rebuilding the emergency brake system so as to increase the distances referred to. Fig. 5 is intended to show just what the trouble is, and why.

Looks Like Poor Distribution of Mixture

Editor The Automobile:

[2,373]—I have a 1909, 30-horsepower automobile that has caused me to awaken quite early in the morning. Cylinder No. 4 pops back and shoots out of the carbureter a portion of the charge. Have taken the machine to three shops, each of which stands high in its superior knowledge of gasoline engines, but have received no benefit. The cams have been examined; the valves set and polished, and the engine tested for a hidden crack, but all to no good. I have discovered by taking out the regular auto gasoline and putting in the tank 72 test that I can to a great extent overcome it, but it is not always convenient to use high-grade gasoline. Now, I notice that the manifold pipe is of a rather large size, and I also notice that the back end or the point farthest from the front cylinder is about three-eighths of an inch low, or the point where it is fastened to the cylinder No. 4 would have to be raised three-eighths of an inch to make it on a level. Now would gas drift faster to the higher end of the pipe, and would it have a tendency to form a pocket in the lower end of the manifold pipe? Should the manifold pipe be on a level when the machine is on level ground? T. J. Bossert.

Hollywood, Cal.

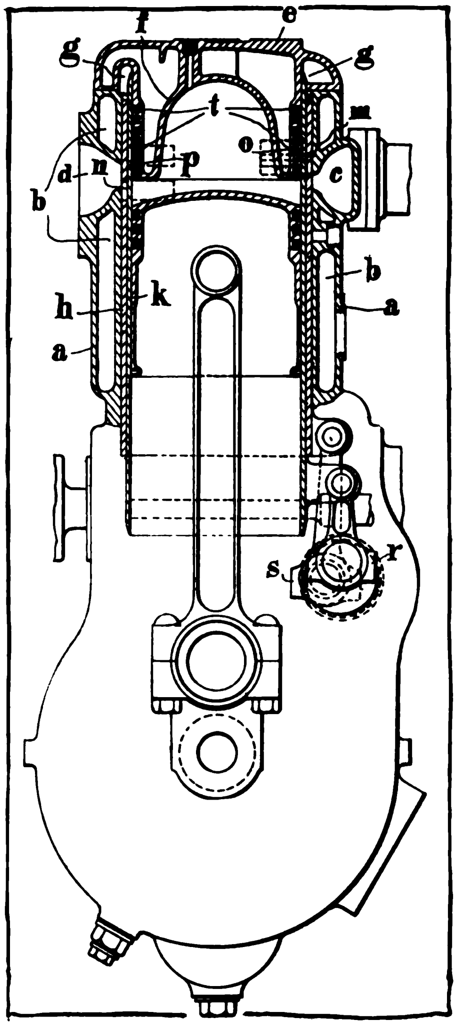

Fig. 4—Cross-section of the Knight motor as it was put into practice in the British Daimler plant

Popping in the carbureter is due primarily to the fact that the speed of travel of the incoming mixture is below the speed at which the flame propagates in the same. When the mixture is ignited in the cylinder of a motor it burns with a certain speed depending upon the proportion of gasoline to air, and also to the amount of the compression, conditions of scavenging and tem-

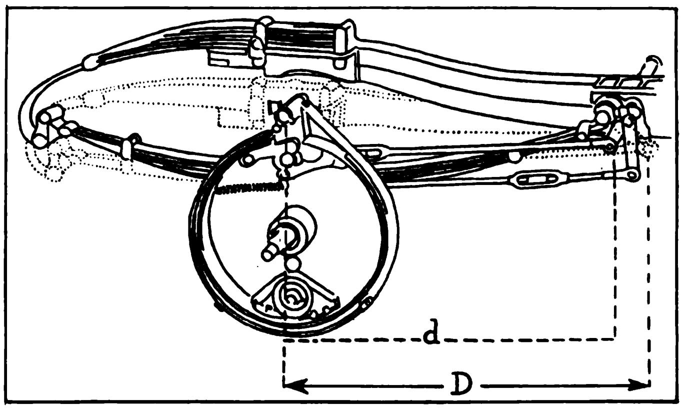

Fig. 5—Lever motion coupled up too short, so that brakes are thrown out of action when tonneau is loaded

perature. The speed at which the mixture passes through the intake depends first upon the depression, or difference in pressure, and second upon the size of the intake manifold. If the manifold is too large the speed of the gas will be so low, all other conditions fixed, that the flame will travel back into the carbureter, producing the phenomenon complained of. The way to overcome this difficulty is to use a manifold small enough in area to bring about the desired speed of travel of the gas in the direction of the cylinder. A way to reduce the tendency to this is to lower the inflammability of the mixture; this may be done by adding gasoline to the same. The latter may be accomplished by increasing the depression in the depression chamber of the carbureter, and this is brought about by reducing the quantity of auxiliary air admitted. But if the manifold is so designed that popping back takes place due to bad distribution, there are only two ways that we now think of for overcoming the trouble. The first remedy lies in the replacing of the defective manifold with one that is properly designed. The second remedy depends upon so timing the motor that there will be a definite lapse of time between the closing of the inlet and the opening of the exhaust valve. If the exhaust valve is closed 10 degrees after center, and the inlet valve is open 15 degrees after center, the difference represented by 5 degrees will be sufficient to overcome the trouble, it is believed. In addition to this timing remedy, it will be well to adjust the carbureter so that it will deliver a somewhat richer mixture than it does when popping occurs.

Don't

BEING STILL ANOTHER INSTALLMENT OF TERSELY-PUT ADVICE—THIS TIME DIRECTED TO THE PROSPECTIVE PURCHASER OF A CAR, AND THE READING OF WHICH MAY SAVE HIM TIME, TROUBLE AND MONEY

Don't make the mistake of examining every automobile manufactured if you only want to buy one.

Don't persuade yourself to believe that you can see so many things that you have no use for and then pick out the one idea that conforms with your needs.

Don't flatter yourself that you are so much smarter than anyone else as to permit you to enjoy many demonstrations and not have to pay for taking up the time of the many demonstrators.

Don't get the idea here that they will ask you for money; certainly not, but they will fill you so full of nonsense that you would not know a good automobile if it ran over you.

Don't measure the ability of an automobile based upon its high gear performance on a grade; it may be fitted out with a low gear ratio.

Don't decide as to the general ability of an automobile without observing its performance first on a level and then in hill-climbing work. If the car will travel fast on a level hard road and in addition to this quality has good hill-climbing ability, it is a sign of power and harmony.

Don't select the automobile that you are to pay good money for because it will go like the dickens on a billiard board or a boulevard; you might have to hire a horse to pull it up hill.

Don't figure out that the radiator is amply large for its intended purpose based upon your observation while the car is traveling fast; a good automobile can almost do without a radiator at the higher speed.

Don't forget that the ability of a radiator and the cooling system in general will best be brought out when a car is traveling on a long sandy road with the motor working at approximately full load and the sun beating down doing its prettiest.

Don't abandon the idea of finding out how good the cooling system is if a long sandy road on a hot day is not available. With the car standing at the curb and the spark retarded, the average poor radiator will throw up its hands.

Don't let the demonstrator persuade you to believe that the radiator is big enough if it offers all the evidences of a steam boiler blowing off.

Don't give up if the demonstrator who sold you a car was able to make it run to your satisfaction and you are not able to duplicate the performance; it merely goes to show that the demonstrator knew how to run the car—you don't.

Don't inflict your new-found trouble on your unprotected neighbors; they might want to go to Sunday-school. Anyway, if you persist in running your car on a retarded spark, the motor will overheat, but if you do not know what lubricating oil is for, the bearings will squeak. What you want is horse sense, not your neighbor's sympathy.

Don't race off to the sales agency and talk about being stuck after you buy a car and it fails to come up to your final expectation. Don't expect anything. Decide on what you want first, then buy the car.

Don't mistake a fine line of talk from an engaging salesman for chrome nickel steel in a crankshaft or other refinements in a car. Just keep in mind the fact that the salesman don't make the car.

Don't try to tell the maker of an automobile how to build it just because you want one. Put in your time finding the particular make that will do the work you have to perform.

Don't think you know more about it than the designer just because you read a technical paper; the paper may be barking up the wrong tree.

Don't overlook the fact that there are 360 degrees in a circle and a statement may be based upon the perspective as viewed from any one of these angles; this is the reason why a little knowledge is dangerous.

Don't jump to the conclusion that the cost of maintenance of a car will be low if the purchase price is high. The actual cost of maintenance is more likely to be in proportion to the square of the velocity of the car and substantially independent of the purchase price.

Don't buy a seven-passenger car before your family expands sufficiently to take up the reserved seats in the tonneau; your neighbors are mighty apt to fill the vacancies.

Don't imagine that an empty tonneau costs little or nothing; it is difficult to keep the rear wheels on the road when the car thrashes along at high speed under the influence of a heavy body that is not properly weighted down.

Don't forget that it is a costly expedient filling the tonneau even if it is the lesser of two evils.

Don't reach the conclusion that the carbureter is large enough for the intended purpose even if it does carburet at both high and low speeds. The carbureter might fail when the car is half-way up a long steep hill.

Don't assume anything. If the car you put your money in has no means for telling you how much lubricating oil there is in the crankcase, take all your chances in one direction only; keep putting in lubricating oil.

Don't use the Kentuckian's whiskey test as a means for determining the character of the lubricating oil you propose to use in your motor; it may look like oil, or it may smell like oil, and it might even taste like oil, but in spite of all these necessary qualifications it might act like trouble.

Don't experiment with lubricating oil; if the brand you are using proves to be efficacious it is your good friend—stick to your friends.

Kingston Carbureter

SECTIONAL ILLUSTRATION INDICATING RELATIONS OF PARTS: FLOAT IS CONCENTRIC; FLOATING BALLS METHOD OF REGULATING AUXILIARY AIR DEPICTED

JUST in proportion as the fuel problem becomes an issue, so does the problem of carburetion have to receive the attention that will bring the capability of the carbureter up to the more exacting requirement. There are other conditions that are slowly being recognized as of such influence that it will be to the point to discuss them and to try and form an estimate of their influence on the performance of motors and ultimately upon the automobile art.

As the number of automobiles in use increase, and the character of the skill of the owners thereof falls to lower levels, it is rendered more apparent to those who have to cope with the problems involved that greater effort must be made to simplify the equipment used, and by so doing compensate for the shortcomings of the users. That there is a falling off in skill, taking it under average conditions, is true, and this growing condition is ascribed to the fact that the major portion of the new additions to the ranks are men who know little or nothing about the mechanical problems involved in the make-up and maintenance of automobiles.

The time was when it seemed that the owners of automobiles would have to learn how to master the complex problems involved, but the whole situation was so much improved within the last few years that the real hope of betterment lies in another direction. Primarily, it would be a Herculean task to teach the better portion of 500,000 owners of automobiles how to do all the things that would have to be accomplished were it not for the improvements wrought, and the simplification of the automobile down to the level that makes it possible to place so complex a machine in the hands of the average man.

That carbureters represent much in the operation of a motor is a matter that is now well recognized, and in order to fully appreciate the questions of carburetion it will be necessary to digress a little and recount some of the more pressing demands. Taking the Kingston type of carbureter as the subject: using it to illustrate the points to be made, attention is called to Fig. 1, which is a section of the carbureter in which D is the primary air intake through which the initial air passes along to the depression chamber, by the nozzle, up to the mixing chamber above. The flow from the mixing chamber is impeded by the butterfly valve, and when the same is opened, the mixture flows past to C, which is the point of connection of the intake manifold, the same leading to the combustion chamber of the respective cylinders of the motor.

In the meantime the gasoline flows in through G into the float bowl when the float K lowers, there being a needle valve in the narrowed portion of the passageway, and as the depression is induced by the suction of the motor, the gasoline passes out of the float bowl to the nozzle. There is a needle valve A placed to alter the size of the nozzle and regulate the amount of gasoline that can pass out of the nozzle into the depression chamber under a given difference in pressure.

The mixture that is made by the flow of initial air past the nozzle in the depression chamber is too rich to be of service, and the next step in the process of carburetion is in the form of auxiliary air; this air is taken in through orifices, of which there are five; one of the orifices shows in section in Fig. 1 at L and the cover to the same is indicated as N at a point just over the ball. Referring to Fig. 8, the five covers over the same number of floating balls are indicated as B1, B2, B3, B4 and B5. In this figure the covers over the gasoline intake is indicated as G1.

In order that the reader will better understand the design and construction of the carbureter, reference will be had to reproductions of the carbureter. Fig. 4 shows the exterior of the carbureter looking at one side in which G1 is the gasoline intake, A2 is the fitting at the bottom for the primary intake, A1 indicates one of the auxiliary air intakes, and P1 is the mechanism for use in priming the motor if the occasion requires. Transferring the attention for the moment to Fig. 5, the letters of reference denote the following: A2 is the orifice of the primary air intake, B6 is the float bowl of the carbureter, G1 is the gasoline intake, A1 is one of the five orifices of the auxiliary intake, L1 is the lever placed to control the butterfly valve, and N1 is the exposed portion of the stem of the needle valve connected with the nozzle; this valve is manipulated by screwing it in to reduce the supply and out to increase the same. In order that the adjustment will stay permanent, a clamping screw is provided. Figs. 9 and 10 show several of the component parts of the carbureter and are offered for the purpose of acquainting the reader with the mechanical refinements that obtain in this work.

Necessities of the Occasion Discussed in Detail

If the reader can be brought to a good realization of the requirements and the methods in vogue for accomplishing them, the aim will have been accomplished. Take the needle valve for illustration: by referring to Fig. 2 the results obtained by manipulating the same will be understood. In this figure the ordinates read needle valve setting in degrees, and the abscissæ are plotted in terms of thermal efficiency. The particular motor was run at 1,000 revolutions per minute and the load was changed from 10 to 30 horsepower by 5-horsepower increments. The thermal efficiency was maximum when the least amount of gasoline was used, considering the delivery of the horsepower stated in each case. It will also be observed that the thermal

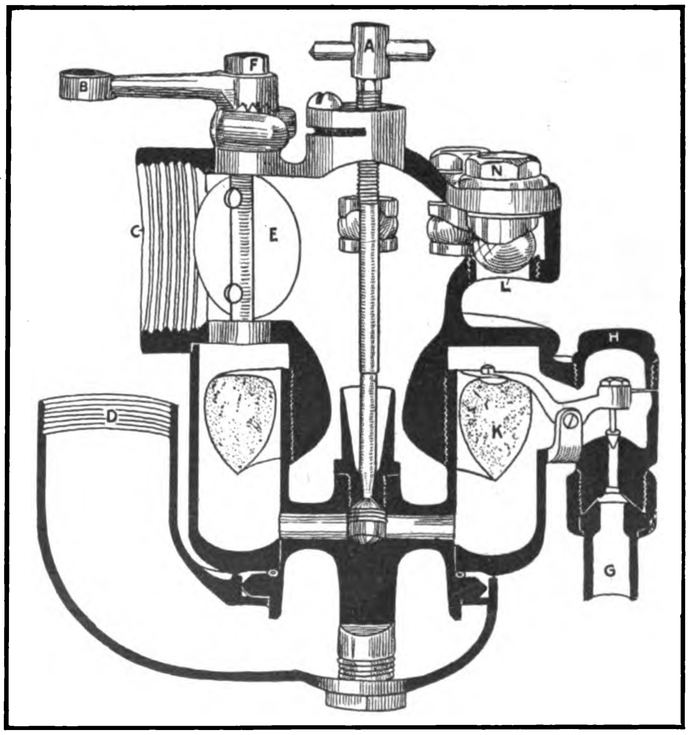

Fig. 1—Cross-section of the carbureter showing the primary intake, needle in the nozzle, floating balls, concentric float in the bowl, and method of adjustment

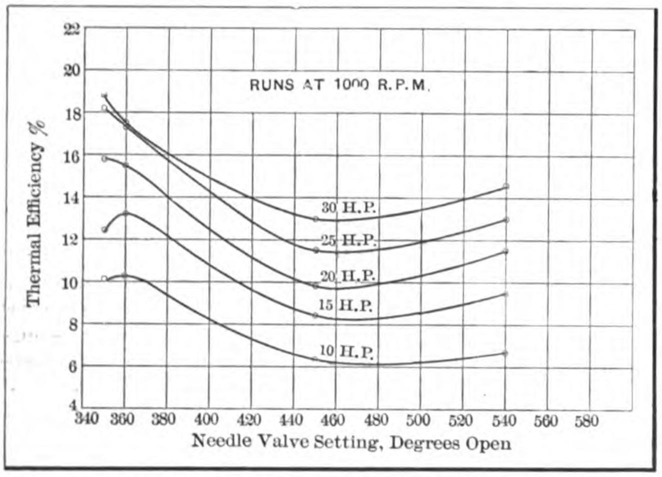

Fig. 2—Chart designed to tell the thermal efficiency of a motor running at different powers and a constant speed for several settings of the needle

efficiency was maximum at maximum loading of the motor.

The thermal efficiency for different loadings, at a constant speed and with 350 degrees of nozzle opening, according to the chart, may be repeated as follows:

THERMAL EFFICIENCY FOR DIFFERENT LOADS AT A CONSTANT SPEED

Horsepower with Nozzle at 350 Degrees Open	Thermal Efficiency in Per Cent.
10	10
15	12.3
20	15.89
25	18 12
30	18.83

The curves plotted for each horsepower output show a decreasing thermal efficiency as the nozzle is opened more, and in every instance the efficiency falls off rapidly as the quantity of gasoline is increased, which is what happens if the nozzle is opened more. One more point and this part of the subject will be passed: as the flow of gasoline is increased beyond a certain point, the thermal efficiency increases perceptibly, but the amount of this increase is not sufficient to be of any avail in every-day work; the best position of the nozzle is that which will afford the highest thermal efficiency, but the reason underlying this fact is not merely on account of the saving in gasoline that will be effected. It will be understood that gasoline, if it is fed into the cylinders of the motor in liquid form, and in excess, will "coke," and the serious trouble that follows the deposits of carbon over the combustion chamber surfaces will then have to be coped with. It is proper, therefore, to limit the flow of gasoline to that amount that will afford the highest thermal efficiency, independently of the fact that a little more might be obtained from the motor by enriching the fuel.

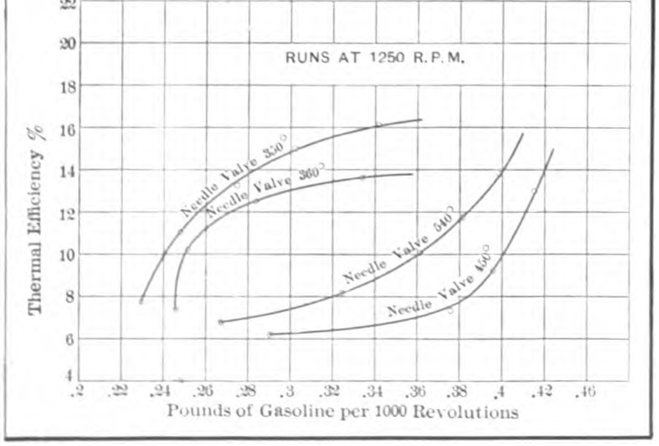

Fig. 3—Chart designed to show the thermal efficiency under different conditions of gasoline consumption at a constant speed

Referring to Fig. 3, another phase of this story will be recognized. In this chart the ordinates are plotted in terms of "pounds of gasoline per 1,000 revolutions of the motor" and abscissæ are plotted in terms of "thermal efficiency." In this case the speed of the motor was maintained at 1,250 revolutions per minute, and the needle valve was adjusted to 350, 360, 540 and 550 degrees; a run was made for each of these adjustments and the thermal efficiency was noted in each single instance.

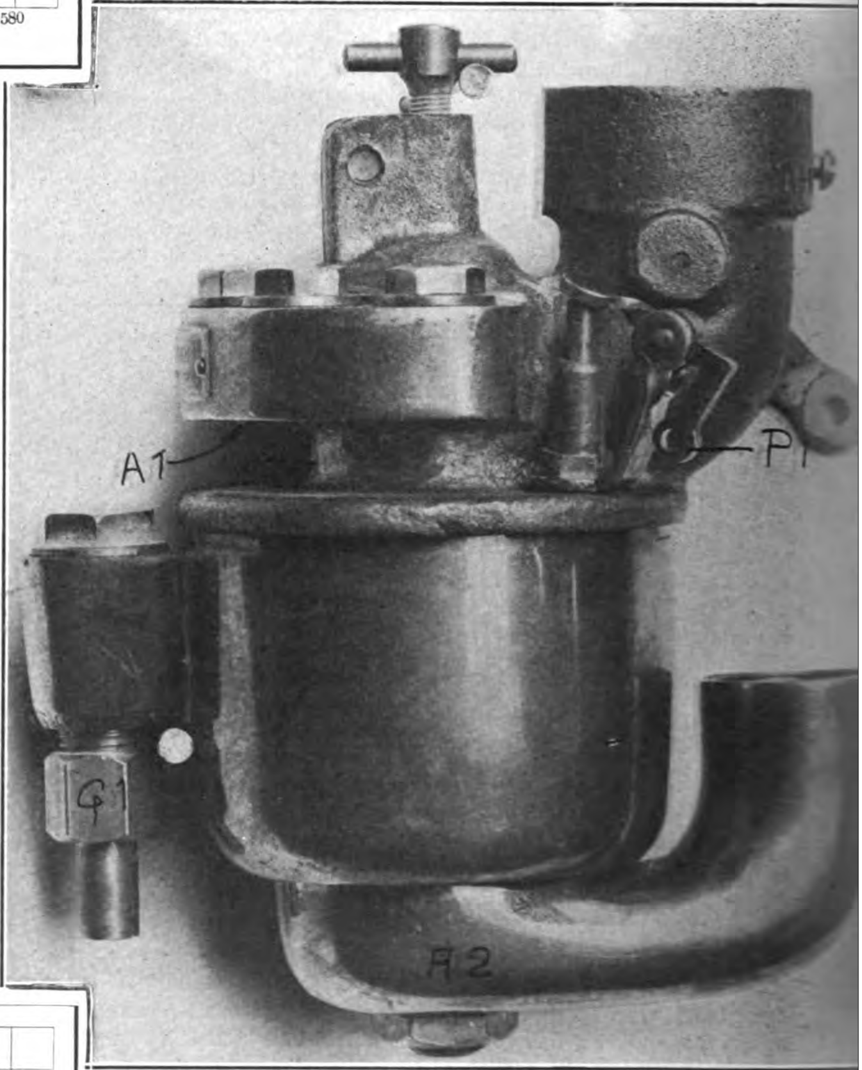

Fig. 4—Illustration of one side of the carbureter, showing the locati
the priming mechanism

The highest thermal efficiency was realized with the closest adjustment of the needle, *i. e.*, 350 degrees; this is as it should be, according to the information obtained in Fig. 2. With this close adjustment, the thermal efficiency was below 8 per cent. with the lowest power taken from the motor, and slightly above 16 per cent. with the highest register of power. The gasoline consumption of the motor advanced from 0.228 pounds per 1,000 revolutions with the lowest power, to 0.34 pounds of gasoline per 1,000 revolutions when the motor was delivering maximum power. This shows that the increase in gasoline that is necessary for good performance may be expected to take place automatically within limits. The second curve, with the needle turned to 360 degrees, shows that the thermal efficiency increases rapidly at first, but falls away, never reaching the level that obtains with the nozzle turned to 350 degrees. This performance offers a bare insight into the fact that if the motor is to operate at low power, slightly more gasoline will be worth considering, but under the conditions that obtain in automobile work, flexibility and a wide range of performance are assets that cannot be disregarded. Glancing at the curve with the needle turned to 540 degrees, it presents the astonishing condition which is represented by a reversal of the curvature as compared with the curvature when the nozzle is turned to a maximum of 360 degrees. The 450 degree position of the needle valve is the worst of all. This is further evidence of the fact that carbureters are very prone to dead points in their performance, and how to eliminate these dead points is one of the serious problems to be coped with by makers and autoists.

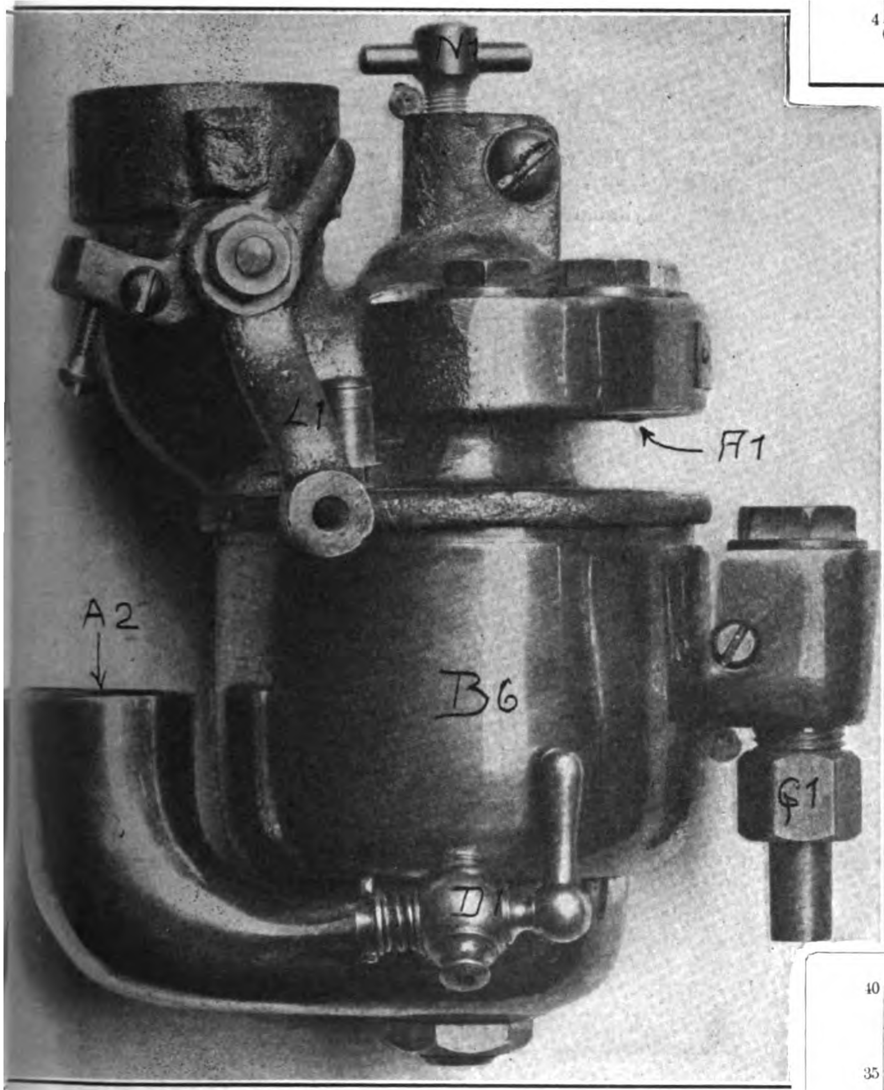

Fig. 5—Illustrating the other side of the carbureter and the location of the butterfly valve lever, draincock, and needle valve adjustment

Referring to Fig. 6, which is a chart designed to show the thermal efficiency and delivered horsepower when the motor is running at 1250 revolutions per minute, and the needle valve is given positions represented by 350, 360, 450, and 540 degrees of opening, this chart is corroborative of the information afforded in the charts Figs. 2 and 3. In this case the horsepower is plotted as ordinates and the thermal efficiency is given value as abscissa. Here again it is indicated that the highest thermal efficiency comes with the needle valve given the least opening, *i. e.*, 350 degrees. It is also shown that the thermal efficiency is lowest when the horsepower output is lowest, and at 350 degrees opening of the needle, the following is approximately true:

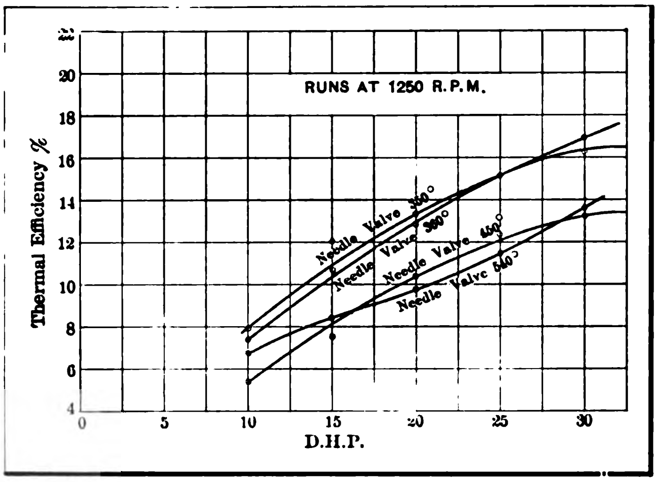

Fig. 6—Chart constructed to show the thermal efficiency for different needle valve settings and varying power with the motor running at a constant speed

HORSEPOWER AND THERMAL EFFICIENCY AT A CONSTANT SPEED

Delivered Horsepower at 1250 Rev. Per Minute	Thermal Efficiency in Per Cent.
10	8
15	10.45
20	13.56
25	15.2
30	16.21

An examination of the curve plotted for 360 degrees shows that the thermal efficiency is lower at all ratings up to 25 horsepower. Beyond 25 horsepower the slightly increased flow of gasoline adds somewhat to the thermal efficiency; the difference is not great, however. It is only when the needle valve is given a twist of 450 degrees that the thermal efficiency falls off considerably, and the 540 degree position of the needle valve affords varying results interlaced with the 450 degree position.

At all events, a study of these charts shows the interrelations of power, speed, and thermal efficiency, and points the way to proper carburetion. It is obvious that the auxiliary air control must be in precise accord with the requirements as measured by the flow of gasoline if the mixture is to be efficacious for the purpose. It is recognized that the amount of energy which will be taken into the cylinder of a motor is in direct proportion to the weight of gasoline sucked in, but this in itself is of

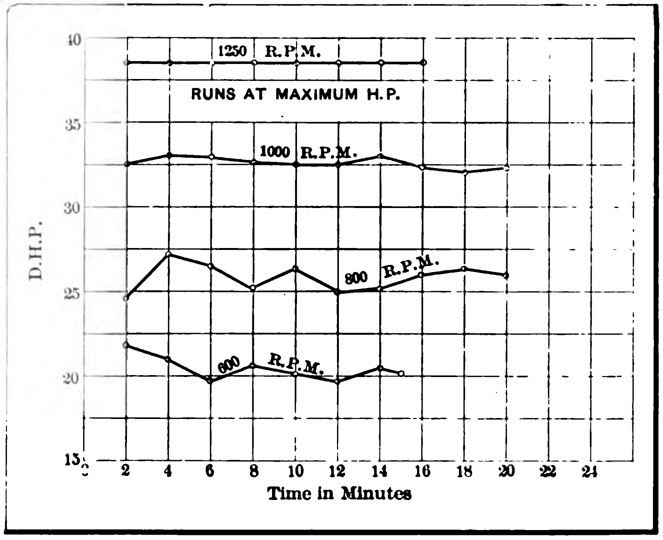

Fig. 7—Chart designed to show the constancy of the power delivered at different speeds in time

small avail. The energy must not only be taken into the cylinder but it must be in an acceptable form. To be in this form it is necessary that 8,000 volumes of air shall have intermingled with it one volume of (liquid) gasoline, the same to be vaporized, and so thoroughly intermingled with the air that during the process of combustion each molecule of hydrogen or carbon will be introduced to its affinity, oxygen, and the products of combustion resulting will be in the form of water and carbonic acid plus the regular quota of nitrogen, in the absence of unburned carbon, or any of the other compounds having a fuel value.

Fig. 7 is a chart which was designed to show the performance of a motor at the various speeds, and the variations in the horsepower at the speeds, also the effect of the malperformance of the carbureter, ignition, etc. At 1250 revolutions per minute the particular motor delivered 37.6 horsepower uninterruptedly and without variation during the time of the test. When the speed of the motor was dropped to 1,000 revolutions per minute, the power was substantially 32.5 horsepower, but there were a few variations above and below this level during the time of the test. At 800 revolutions per minute, the lowest point in the power curve was 24.5, the highest point 27.2, and there were considerable variations in the power delivery during the time of the test; but when the speed was dropped to 600 revolutions per minute, the lowest delivery was slightly under 20 horsepower; the maximum was about 22, but the variations were sharp and relatively wide. When a carbureter is doing exactly what is required from the best point of view, the performance will be in the form of a straight line as here shown for 1250 revolutions per minute, but when the carbureter falls below this fitting requirement and reaches the level as here indicated at 600 revolutions per minute, flexibility and range are scarcely normal expectations.

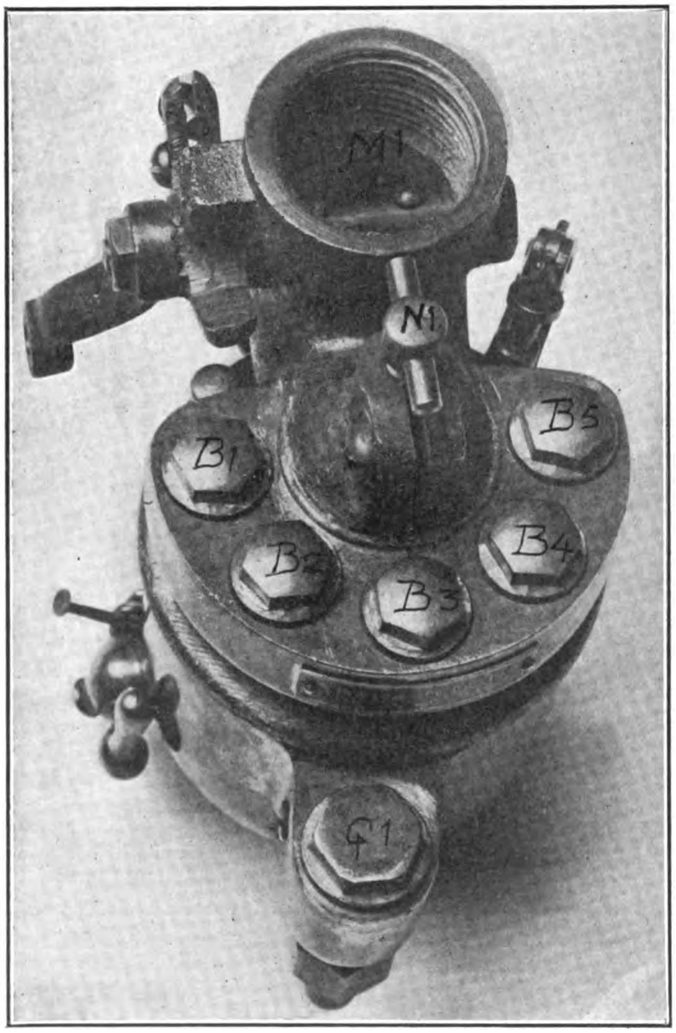

Fig. 8—Looking down upon the carbureter, showing the orifice for connecting the intake manifold and the caps covering the floating balls

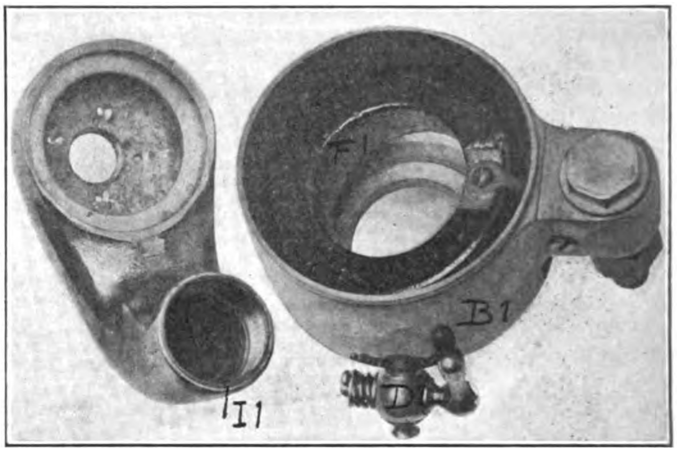

Fig. 9—To the left the primary intake casting, to the right the float chamber, with the concentric float in position

Since it is admitted that the difficulties involved in fixing the flow of gasoline out of a nozzle are few and readily coped with through the good office of a needle valve or in other suitable ways, the troubles which bring on lack of flexibility and crankiness of performance must be due to lack of proper proportion of the interrelating functional members.

The particular point involved in the construction of this carbureter that has to do with the softening of the performance and the smoothing out of the variables, is wrapped up in the plan of employing bronze spheres to obstruct the flow of auxiliary air, excepting in so far as the spheres are lifted by suction, and the air flows in through the openings thus afforded, under the impetus of a difference in pressure as represented by the depression within the mixing chamber overcome by the atmospheric pressure of 14.7 pounds per square inch.

These balls are prevented from departing from their position of vantage by the plugs in Fig. 1, which have concave ends conforming to the curvature of the spheres and which are screwed down so closely that the spheres are permitted to lift off of the seat a predetermined distance. The spheres are regulated as to weight by selecting materials of the right specific gravity, so that they lift when the depression is so regulated as to demand the presence of auxiliary air. The five spheres are of one diameter, and as the material is the same in each of them, and of same weight, they do not lift simultaneously under a given depression because they do not all occupy positions of vantage in the stream of inrushing primary air, hence there is

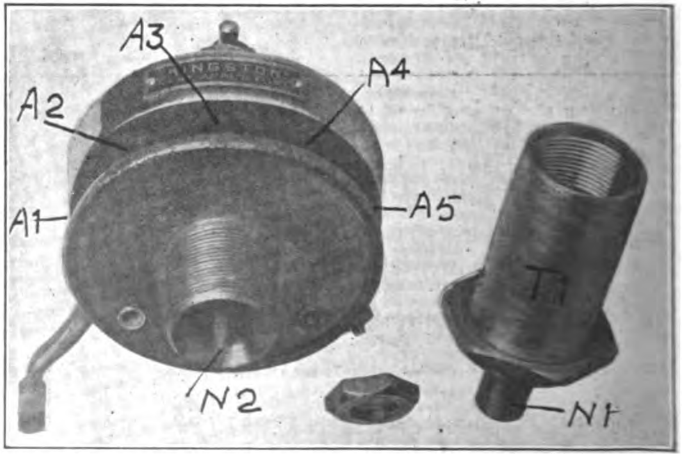

Fig. 10—To the left, showing the floating ball housing and the method of connecting the same to the lower half; to the right, the accommodation casting by means of which the two parts are joined

a variation in the depression, considering it locally, sufficient to permit of taking advantage of a difference in the time of the lifting of the several balls, so that great flexibility of the motor performance is to be relied upon, and finally it is worth while remembering that the balls are constant as to weight, cannot vary in the amount of the lift and are free from any mechanical incongruity such as would tend to alter their ability to function in service, as the result of wear, atmospheric conditions, or changed environment. It is claimed, therefore, for this type of carbureter, that having fixed the proper sizes of the balls, the right number, and the position that they should occupy, on a laboratory basis, the experimental phase of this situation is done for on a basis of finality, leaving nothing for the automobilist to adjust in practice, excepting to coax his motor up to its right performance by altering the flow of mixture from the carbureter through the combustion chamber, by changing the position of the butterfly valve E, Fig. 1, which is a matter of altering the angular position of the lever B, the same to be connected up with an accelerator pedal which may be located at a convenient point.

G. & A. Carbureter

DESCRIPTION OF AN AUTOMATIC ADJUSTMENTLESS CARBURETER OF FRENCH DESIGN WHICH IS BASED ON THE PRINCIPLE OF THE VENTURI TUBE

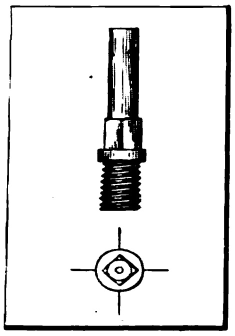

Fig. 1—G. & A. carbureter jet

IT has been the aim of designers of carbureters to evolve something that is entirely automatic, requiring no adjustment whatsoever, consequently having nothing to get out of order.

Messrs. Grouvelle & Arquembourg, of Paris, have for many years been gaining a reputation with their carbureter on famous racing cars, and for this reason they have made a more careful and scientific study of this matter. In fact, these studies date back to the very early days of the automobile. Their experiments have been thorough and extensive. In all this time data has been collected and tabulated on carbureters of several of the most successful cars, until to-day the product of all this experience is a carbureter without an adjustment.

Grouvelle & Arquembourg were among the first to manufacture radiators for the different well-known cars, such as Panhard, Mors, Darracq, etc. The distinctive features of their carbureter are the shape of the choke tube, the ball cage air valve and position of the jet.

The Venturi tube, which is the basic principle of the carbureter under discussion, derives its name from an Italian physicist who became known in 1791. Experiments show that Venturi invented nothing, but rather controlled a fact known to the Romans. A concession of water in ancient Rome was given according to the diameter of pipe and was so charged for, but the defrauder, to increase the amount of water supply, placed a cone in the outlet. Venturi in his book on Industrial Physics says that the supply of air through an outlet is made of two cones, one convergent of 30 degrees and the other divergent of 7 degrees; then the quantity of air going out is four times greater than if the outlet was plain.

Piston displacement was taken as a basis from which all calculations were made, and although many criticisms may be offered for using this as a starting point, the contentions to the contrary are as follows:

It has been shown by many eminent engineers, and notably by Arnoux in France, that piston speeds have practically reached an upper limit; in other words, that piston speed and maximum power are the same, regardless of the stroke. It is, therefore, very reasonable that piston displacement should be taken as a basis, for in ordinary practice it is the displacement of the piston in the main which determines the gas speeds in the carbureter passages.

It has been shown that when any fluid passes through a pipe of variable section the quantity passing any given section in a given time is the same; such being the case, the velocity of the fluid in the various sections is inversely proportional to the areas of the sections. Hence, it is evident from the foregoing considerations that the pressure is greatest at the largest section and least in the smaller. A practical application of this principle was made in the construction of the Herschel-Venturi water meter, and in later years this principle has been applied to the curbureter design.

To thoroughly understand the principle and appreciate the advantages of the Venturi tube in the carbureter design we will consider Fig. 6. The form of discharge tube here shown is interesting in that the discharge is greatly increased in the addition of the divergent nozzle at the outlet end, for it is found that the velocity of flow in the throat at (a) is greater than that produced by the head (h). When a pressure gauge is placed at (a) the pressure is found to be less than atmospheric; in fact the fluid is discharging into a partial vacuum, and the velocity at (a) is due to head (h), plus the head due to the vacuum.

An interesting experiment, which shows this phenomenon very strikingly, may be made by taking a glass tube three-quarters of an inch bore, and drawing it to a gradual waist of about one-twentieth of an inch diameter at the center. It is found that when water is forced through the tube at high velocity the pressure is so reduced at the waist that the water boils and hisses loudly—a phenomenon heretofore observed under certain circumstances in the action of carbureters, but one which has not been satisfactorily explained before, as far as can be learned.

In a case that came under observation when a Venturi car-

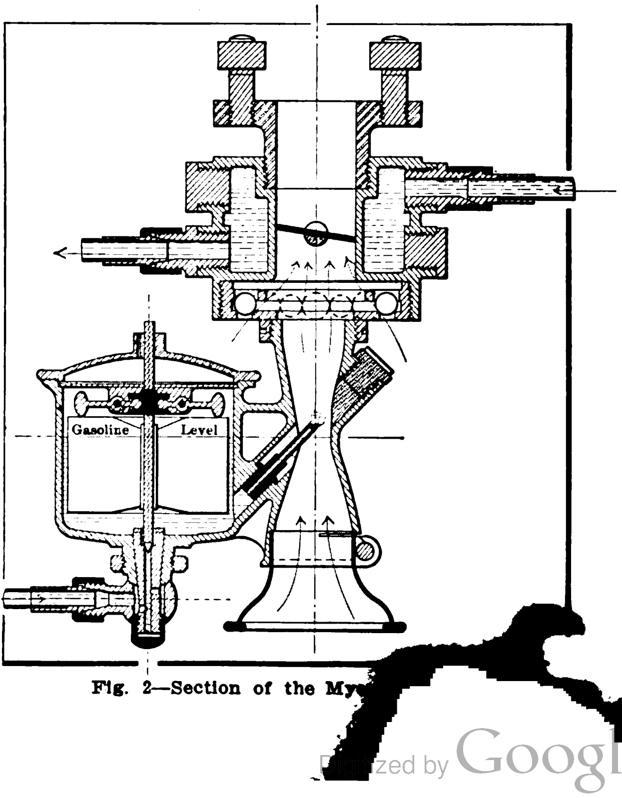

Fig. 2—Section of the My

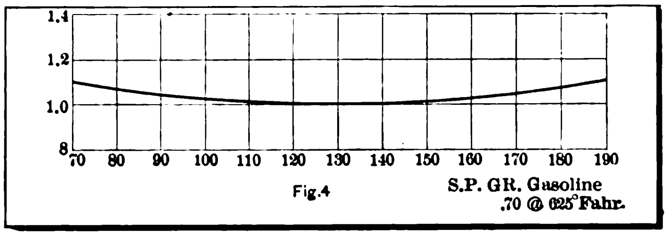

Fig. 3—Diagram showing gasoline consumption in relation to temperature of carbureter jacket

bureter was being tested the hissing was so loud as to be disagreeable. By making the "upstream" end smaller, thereby decreasing the ratio of upstream area to the throat area, the hissing practically ceased. Of interest is the fact that the gasoline in the Venturi throat is actually undergoing ebullition at reduced atmospheric pressure, and this is one of the many causes operating to effect homogeneity of mixture.

The employment of the Venturi possesses the following important advantages: Homogeneity of mixture, as explained above; reduction of wire drawing to minimum; compactness; light weight; ease with which the mixing chamber may be jacketed by water; mixing chamber may be placed in any plane, thus adapting it to any motor design, no adjustable or movable parts.

Mathematical Considerations Regarding the Flow of Fluids in a Venturi tube.

If we consider that there exists a certain pressure head, say "h," causing a flow of liquid in the Venturi tube, it will be seen from Fig. 9 that the principles stated above regarding the flow of a fluid in a tube having various cross-sections A and A' that at (1) the pressure head is

$$h_1 = \frac{V_1^2}{2g}$$

and at (2) the pressure head is

$$h_2 = \frac{V_2^2}{2g}$$

It is clear then that the loss of head between (1) and (2) or the head on the Venturi is given by

$$h = h_2 - h_1 = \frac{V_2^2}{2g} - \frac{V_1^2}{2g} = \frac{V_2^2 - V_1^2}{2g}$$

It will be recalled that the velocities in the different sections are inverse to the areas of these cross-sections; hence we have

$$V_2 = \frac{A_1}{\sqrt{A_1^2 - A_2^2}} \times \sqrt{2gH}.$$

While the velocity of the upstream end of the tube is given by

$$V_1 = \frac{A_2}{A_1} V_2, \text{ and } V_1^2 = \frac{A_2^2}{A_1^2} V_2^2.$$

Now

$$H = \frac{V_2^2 - \frac{A_2^2}{A_1^2} V_2^2}{2g} = \frac{\left(1 - \frac{A_2^2}{A_1^2}\right) V_2^2}{2g}$$

$$= \frac{\frac{A_1^2 - A_2^2}{A_2^2} V_2^2}{2g};$$

hence

$$V_2^2 = \frac{2ghA_1^2}{A_1^2 - A_2^2},$$

from which we find that the velocity at the throat is given by

$$V_2 = \frac{A_1}{\sqrt{A_1^2 - A_2^2}} \sqrt{2gH}.$$

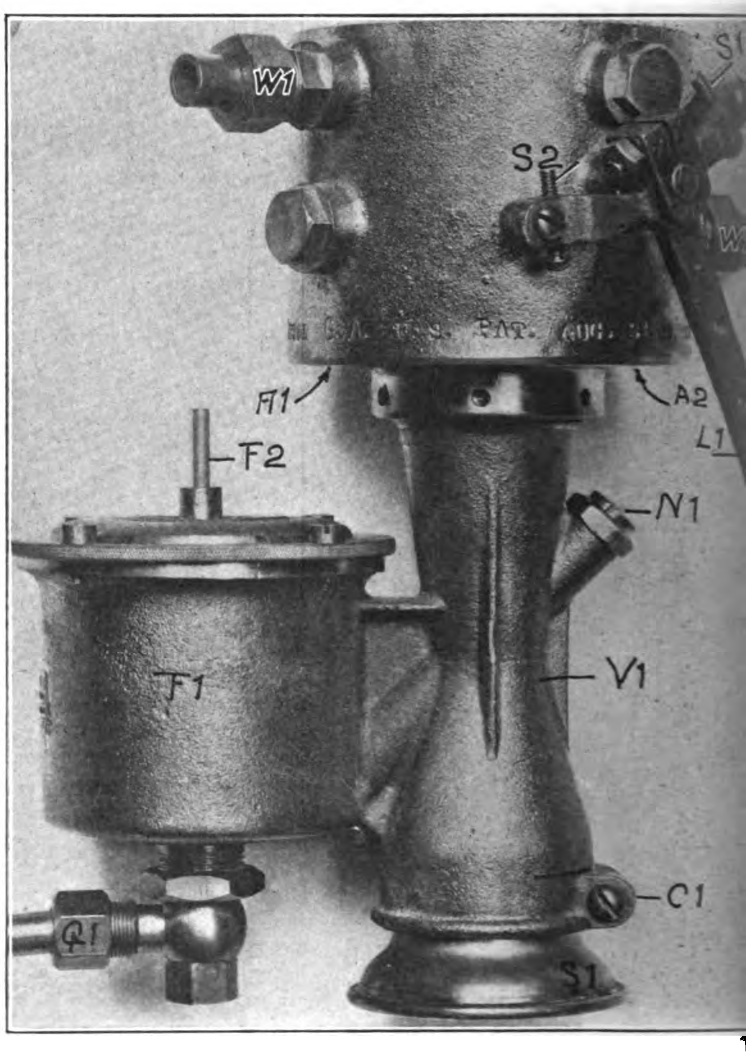

Fig. 4—Throttle side of G. & A. carbureter: S1, adjusting screw for op sition of throttle; S2, adjusting screw for closed position of throttle; W1, for water circulation round water jacket; W2, inlet for water circu round water jacket; A1, ball valves for supplementary air at high speed ball valves for supplementary air at high speeds; L1, lever operating th N1, spray cone, which can be removed to take out jet; S, brass cove with covered bottom; C1, release screw for same; F1, float chamber; F2, needle G1, gasoline intake.

$$\text{Throat ratio} = \frac{A_2}{A_1}.$$

The throat ratio for G. & A. carbureters has been taken as 1:4; we then have

$$\frac{A_1}{\sqrt{A_1^2 - A_2^2}} = \frac{4}{\sqrt{4^2 - 1^2}} = \frac{4}{\sqrt{15}} = 1.0328.$$

Hence

$$V_2 = 1.0328 \sqrt{2gH}.$$

From this expression we have

$$V_2^2 = \frac{2ghA_1^2}{A_1^2 - A_2^2} = \frac{2gh}{\frac{A_1^2 - A_2^2}{A_1^2}} = \frac{2gh}{1 - \frac{A_2^2}{A_1^2}}$$

$$= \frac{\frac{2gh}{1 - A_2^2}}{A_1^2}$$

and

$$2gH = V_2^2 - \frac{A_2^2}{A_1^2} V_2^2.$$

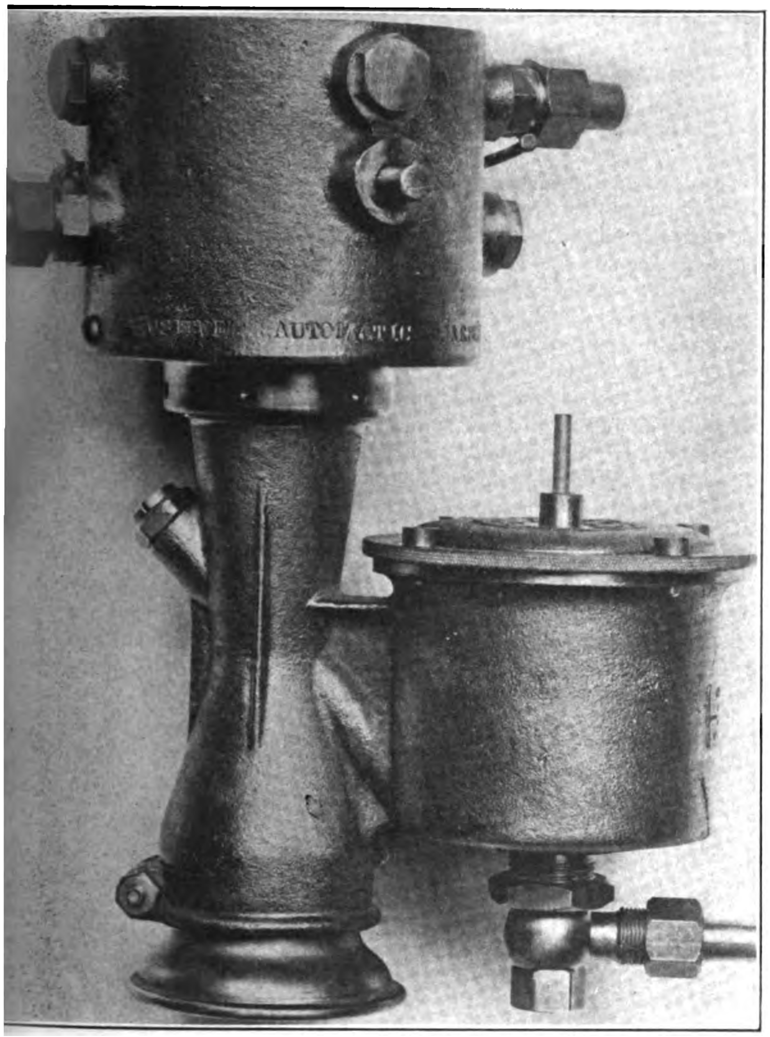

Fig. 5—Opposite side of G. & A. automatic carbureter

hence

$$V_2^2 = 2gH + \frac{A_2^2}{A_1^2} V_2^2$$

$$= 2gH + V_1^2$$

$$= 2g\left(H + \frac{V_1^2}{2g}\right)$$

and

$$V_2 = \sqrt{2g\left(H + \frac{V_1^2}{2g}\right)}$$

Thus it is seen that the velocity at the throat will be that corresponding to the head on the Venturi plus the head corresponding to the velocity of approach in (1). By velocity of approach

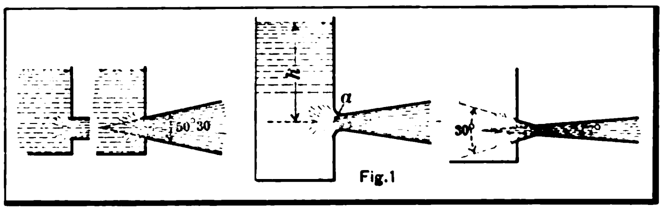

Fig. 6—Example of discharge tube with convergent cones

we mean the additional velocity gained by the moving liquid prior to reaching the throat. From measurements made upon carbureters which give very good speed torque characteristics, the following formulæ for the design of the Venturi are derived.

Referring to Fig. 7—

Let V = piston displacement in cubic centimeters,

d_1 = diameter in centimeters of Venturi throat,

d_2 = diameter in centimeters of Venturi facing upstream,

d_3 = diameter in centimeters of Venturi facing downstream,

A_1 = area in square millimeters of Venturi facing upstream,

A_2 = area in square millimeters of Venturi throat,

A_3 = area in square millimeters of Venturi facing downstream,

L = over all length in centimeters,

t = thickness of tube in millimeters; then the following formulæ give excellent results:

$$\frac{V}{A_2} = 496$$

$$A_2 = \frac{V}{496}$$

$$d_2 = \sqrt{a_2} \times 1.128$$

$$d_1 = \sqrt{a_2} \times 2.584$$

$$d_3 = d_1 - .5\text{cm.}$$

$$A_1 = A_2 \times 5.42$$

$$L = 6.05 \times d_2$$

$$t = 1.5 \text{ to } 2.5 \text{ m/m}$$

Heat Jacketed Carbureters

From tests that have been carried out it seems that the fuel consumption decreased with an increase of jacket temperature for a given output, but only up to a certain point, after which an increase was observed. The most effective temperature seems to be about 110 deg. Fahr.

During these tests it was incidentally found that in order to keep the Venturi tube of the carbureter at 110 deg. Fahr, supplying mixture to a motor of 100 m/m (3.93 in.) x 112 m/m (4.40 in.) it required an expenditure of 45.5 B.T.U. per minute, or approximately 1 horsepower. The motor ran at 1300 revolutions per minute and consumed 1.1 pints of gasoline per horsepower-per hour. Water jacketing the carbureter is, therefore, instrumental in effecting fuel economy and doing a portion of the work of the radiator. The results of these tests are shown in Fig. 3.

Calculation of Spray Nozzle Orifice

It was at one time thought that the size of the orifice in the spray nozzle could not be calculated, except by a lengthy process of trial and error, but observation of the orifices having the same shape proved that these may be calculated when the Venturi or throat area was determined.

When we deal with a gaseous combustible the determinations of the sections for air and combustible to pass weights of materials in proper

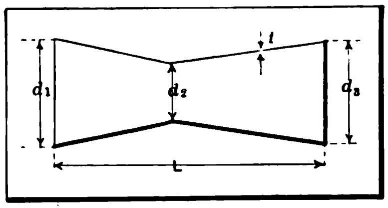

Fig. 7—Diagram of Venturi tube

proportion are given by the following equation, according to Krebs:

$$C = \frac{s\Delta\sqrt{2gH - \frac{D}{\Delta}}}{sd\sqrt{2gH - \frac{D}{d}}}$$

and simplifying

$$C = \frac{s\Delta}{sd}\sqrt{\frac{d}{\Delta}}$$

where

D = density of water,
Δ = density of air,
d = density of combustible,
S = section or area for entrance of air,
s = section or area for entrance of combustible,
H = pressure in millimeters of water,

the ratio between the two areas remains constant, no matter what vacuum is produced by the motor. When, however, the combustible is in the form of a liquid experience shows that the flow of liquid does not follow the air flow, and certain corrective factors must be introduced due to

(a) Differences in level existing between liquid in float and that in the nozzle,

(b) The necessary effort required to overcome the capillary attraction between liquid and nozzle, including the surface tension.

It has been found that when using the Venturi form of mixing chamber and a nozzle having the shape and outside dimensions shown in Fig. 1, the area of the Venturi throat and the nozzle orifice area are connected by the following relation:

$$\frac{S}{s} = 159.$$

Where $S = A_2$,
s = spray jet orifice area.

It is now easy to calculate the size of the spray nozzle orifice by the equation:

$$Sd = \sqrt{s \times 1.128} \text{ in m/m},$$

where Sd = diameter of the orifice.

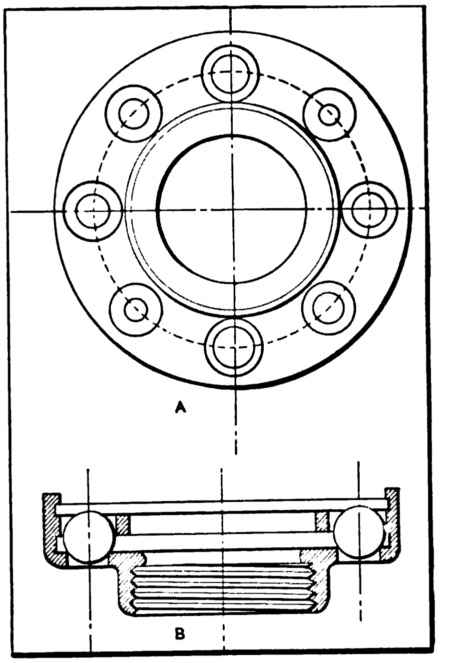

Fig. 8—(a) Top view of supplementary air intake; (b) side view of same

If the shape shown in Fig. 1 is deviated from, the above formula does not apply, for experiments show that the discharge coefficient varies with the shape and size of the nozzle; indeed, recent experiments made show that the discharge coefficient varies also with the variation in bore when the head is constant; this might be expected, since the effect of surface tension and wall friction is smaller in larger nozzles.

The exact size of the spray nozzle orifice also depends on the fitting and workmanship of each motor, as imperfections in igniters, pistons, valve stems, etc., introduce leaks which have to be taken care of by using a little larger jet.

The jet on the G. & A. carbureter can be very easily taken out by undoing the nut N1 (Fig. 4) and using a special tube wrench supplied with the car. It will be noticed that the jet is placed obliquely (Fig. 2), the gasoline atomizing in a conical shape in the smallest part of the tube where the suction is greatest.

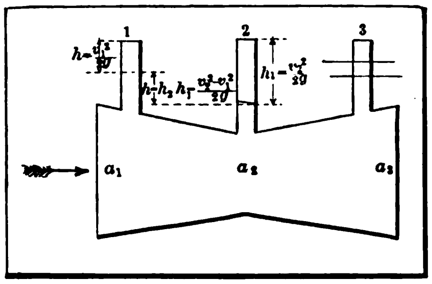

Fig. 9—Venturi tube with various cross-sections

Calculation of Size of Supplementary Air Ports

The flow of liquid from the spray nozzle orifice does not follow the air flow; in fact, as the speed of the motor increases, the liquid from the jet, in virtue of its inertia, flows more nearly in uniform stream, and means must be taken to vary this flow.

In practice it is comparatively simple to control the liquid flow by altering the vacuum or suction by causing an additional air supply at the downstream end.

It will be noticed in Figs. 8a and 8b that the auxiliary air is controlled by a series of bronze balls in a cage placed at the downstream end. These bronze balls are of various sizes and weights, and the ports also vary in diameter. Thus it will readily be seen that the bronze balls will lift successively and progressively, allowing the pressure at the upstream end to be relieved. Each ball has been calculated to the resistance of the port which it controls. Thus it has all the characteristics of the spring valve, but never varying in any change of temperature, giving also a positive mixture at any speed of the motor. This action also answers the purpose of a mechanical turbine.

The suction caused around the nozzle of the carbureter may be kept within the limits necessary to produce a uniform combustible mixture at all speeds by supplying auxiliary air through ports, the areas of which are determined from the equation developed by Krebs. The equation is as follows:

$$S = sC\sqrt{\frac{d}{\Delta}}\sqrt{\frac{H-h}{H}} - A_2.$$

Where Δ is the density of air,
d is the density of combustible,
S is the total auxiliary air area,
s = area of spray nozzle orifice,
H = depression produced by aspiration of motor,
A_2 = Venturi throat area,
h = a factor depending on the difference in level which exists between the liquid in the float chamber and nozzle; also on the necessary effort to overcome the capillary attraction of the nozzle.

A. J. Myers (Inc.), of 244 West Forty-ninth street, manufacture the G. & A. carbureter in New York City, and have delivered several for submarine work. From tests carried out with several 250-horsepower motors it is possible with the G. & A. to run as slow as 90 revolutions per minute and as high as 1,200 revolutions per minute. These submarines are fitted with Jencick motors having eight cylinders of 7-inch bore and 8-inch stroke; the size of the interior of the G. & A. used is 4 inches. Twenty-six of these have been ordered for the United States Government.

Protect the Magneto and Save Trouble

Always keep the magneto covered with a leather or vulcanite protector as it will exclude dust and flies and rain that find their way to this valuable part of the car equipment.

EXTRACTS ON TECHNICAL LINES FROM FIFTY FOREIGN PAPERS—DEVELOPMENT OF THE ELECTRIC FURNACE WITH "WHITE COAL"—SAVING IN TIRE MAINTENANCE—CAUSE OF REFINEMENT OF STEEL—SPREAD OF AUTOGENOUS WELDING

"White coal" and the electric furnace are entering into combinations in Europe which are attracting great attention the technical world and seem to have a tendency to wipe out the national boundaries of important industries, causing them to move to wherever the desired combinations of "white coal" and shipping facilities may be obtained in most liberal measure. The coast of Norway, where countless millions of horsepowers are stored in rapid rivers in the immediate vicinity of deep water ports which are open practically all the year round, seems to be the most favored locality and bids fair to become the seat of industries rivaling or exceeding in magnitude those clustered around Niagara Falls. With the electric furnace applied to steel making and with iron ore of excellent qualities available from Swedish and Norwegian mines, the outlook offers food for reflection also among automobile manufacturers. The manufacture of nitrates used for fertilizing purposes and of nitric acid is one of the new industries located largely in this region, though two large companies have been formed to work on the same general plan at Johannesburg, South Africa, and an Austrian company located at Patsch, near Innsbruck, has parted with rights under its patents to the French company, "La Nitrogène" which contemplates another large installation of this industry, also with water-power, in France. Briefly, the industry consists in robbing the atmosphere of its nitrogen by means of an electric arc furnace which shatters the air into its constituent parts. The Norwegian Nitrogen Company, capitalized at 41 million francs, uses for this purpose 40,000 horsepower taken from the waterfall Svaelgfos at Notodden, Norway, and 15,000 horsepower from Lienfos, another cataract near by. The company's latest public statement shows that a large profit has been earned almost since the inception of the work in 1908, and the company has now taken over a larger waterfall called Rjukan and is arranging to utilize 220,000 horsepower from this source for the German chemical factories of Saaheim. It has also acquired Wamma, Matre and Tyrin, three other "white coal" supplies, and in 1914 will have 500,000 horsepower near tidewater to offer manufacturers at a price of about $40 per horsepower per year. The cost to the Norwegian company is said to be less than $8. The method developed by Birkeland and Eyde for taking nitrogen from the air is of general interest, inasmuch as the heat of an electric arc is applied to a large surface. To this end, two electrodes, consisting of water-cooled copper tubes with closed ends, are placed in a horizontal plane and an arc is produced between them by a 5,000-volt alternating current. At right angles with the electrodes in the same horizontal plane there is placed an electromagnet excited from direct current. The electromagnet deviates the arc into a vertical semi-circle alternately above and below the horizontal plane, and if the alternation is sufficiently rapid the result is a large electric flame half over and half under the electrodes. In practice, the flat electric flame disk is two meters in diameter, and the air carries this flame with it into the furnace and is heated by it to 3,000 deg. centigrade. A considerable portion of the air is thereby split into nitrogen and oxygen, and by rapid cooling these two elements are prevented from again uniting. Schoenherr, one of the engineers of the Badische Anilin & Farbenfabrik (lately much mentioned in connection with Friederich Bayer's new process for the synthetic production of rubber), has also developed an electric furnace for taking nitrogen from air, and this is used concurrently with the Birkeland type at the Norwegian works, and a third method is that invented by Pauling in 1904, used in Austria and now to be used in France. One received a very peculiar impression, says the author, in approaching one of these noiseless factories, which work without raw material, without smoke and almost without workmen. Only electric current, air and water enter into the buildings and none of these elements in a very modern production is visible to the eye. Yet the output reaches high into the thousands of tons annually.—*Mem. et Trav. des Ingénieurs Civils de France,* July.

In occasional dealings with engineers from France it may be convenient to possess a copy of the *Annuaire des Ingénieurs de France,* 1910, 600 pages, published by J. Loubat & Company, Paris, price 5 francs, in which book, just out, are listed all engineers graduated from the technical schools of that country.

That there is a saving in the maintenance cost of pneumatic tires amounting to 15 per cent. by the use of wire wheels instead of the customary wooden wheels for automobiles is said by C. Faroux to be a contention capable of verification in practice; that is, the author maintains that the economy is indisputable, and he estimates it from the data at his disposal at about 25 per cent.—*La Via Automobile,* August 27.

The Road Congress held this year at Brussels passed definite recommendations which had been worked out by the technical commission of the Automobile Club of France, with regard to the maximum speeds at which different classes of automobile pleasure and utility vehicles can be considered as not injurious to road surfaces and also with regard to the width of tires required for different loads and constructions. The details as given seem to represent a compromise between the interests of the automobile industry and those of the road authorities.—*La France Automobile,* August 27.

Owners of an electric furnace of 150 kilowatts, in Germany, wished to ascertain the heat losses due to radiation and thereby the caloric efficiency of their plants. For several days a bath was maintained at a constant temperature of 1250 to 1260 degrees centigrade, and this required the energy of 33 kilowatts. The thermic efficiency at 1250 degrees was thus 150 minus 33, divided by 150, or 78 per cent. At 1425 degrees the efficiency was similarly found to be 74 per cent. In order to reduce these losses due to radiation of the walls, double walls were built around the furnace and in the space between the inner and outer walls gas was burned to keep the walls hot. Apparently the object was to secure an equable temperature throughout the whole mass of molten metal. Trials with much larger furnaces built on the same plan succeeded perfectly.—*Jour. du Four Electrique,* Aug. 1.

"Internacional Matematikal Lexico," by Louis Coutural, 36 pp. G. Fisher, publisher, Jena, Germany, price 1.50 mark, is a pamphlet in "ido" language, giving the equivalents of all mathematical terms in "ido," English, French, German and Italian.

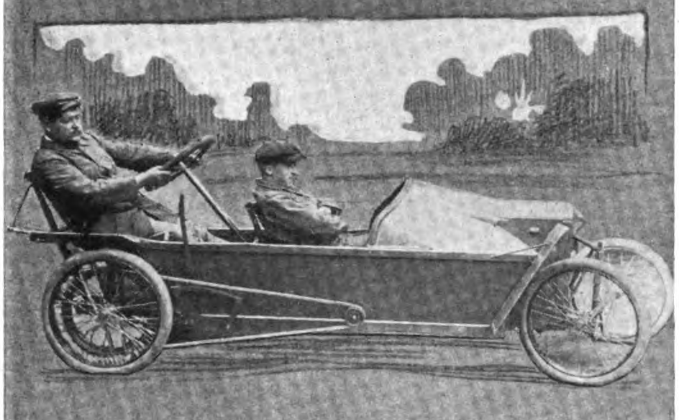
Details of temperature measurements in Nathusius 5 1-2 ton steel furnaces given by Prof. Neumann of Darmstadt disclose heats scarcely higher than those employed in the Siemens-Martin basic process. The well-established refining effects of the electric melt must, therefore, be attributed rather to a non-oxidizing atmosphere in the apparatus than to high heat. The account shows that, while it is possible to maintain much higher heats in the electric furnace, these are not necessary or desirable except possibly for the easier disposal of basic slags.—*Journal du Four Electrique,* September 1.

Calcium carbide to the amount of 2,000 tons is now used in the autogenous welding industry in Europe, as compared with an only slightly larger tonnage used for illumination purposes during the same period of one year. Some silica carbide is also used.—*Journal du Four Electrique,* September 1.

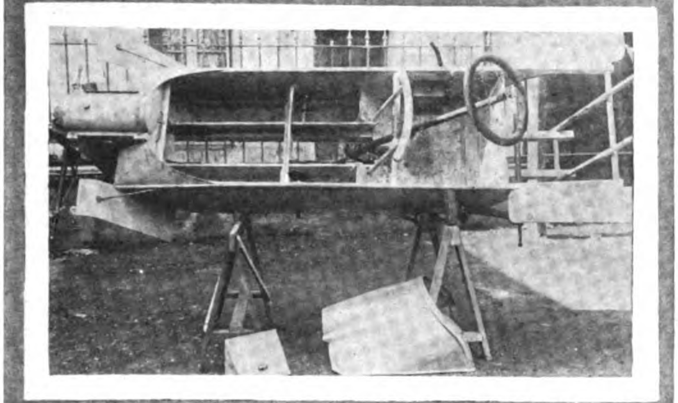
Courses in chemical technology especially intended for students of law and social economy have been instituted at several Prussian universities.—*Zeitschrift für Amewandie Chemie.*

The Littlest French Car

TINY SUBSTITUTE FOR THE MOTORCYCLE THAT IS MEETING WITH FAVOR—IT COSTS LESS THAN $300 AND CARRIES TWO COMFORTABLY



Bedelia Two Seated Runabout



Chassis Tilted Showing Interior

Front View Showing Motor

THE motorcycle being looked upon with disfavor in France, attempts have not been wanting to find a substitute in the form of a small car costing little more than the two-wheeler, while having double the carrying capacity and infinitely more comfort. Among the half-dozen $300 cars which have been brought forward during the past year only two or three have received any support from the public. Among the successful ones is a vehicle known as the Bedelia, and which may truly be described as the connecting link between the motorcycle and the automobile.

This car, which is put on the market complete with a two-cylinder air-cooled motor for a fraction under $300, is an eminently simple yet really practical construction with accommodation for two passengers tandem fashion and a fairly reasonable amount of room for baggage. Its two tubular axles are 99 inches apart, and the track is 36 inches. Between the two axles is carried a long boat-like body, with its main frame of armored wood and the side members covered in with sheet aluminum. At the forward end the body is narrowed to just the width necessary to receive the motor, which may be either a single or a two-cylinder V-type air-cooled model. The sides of the motor are enclosed by a sheet metal sliding panel and the top occupied by the electrically-welded gasoline tank. The front remains open in order that a strong current of air may be carried onto the motor.

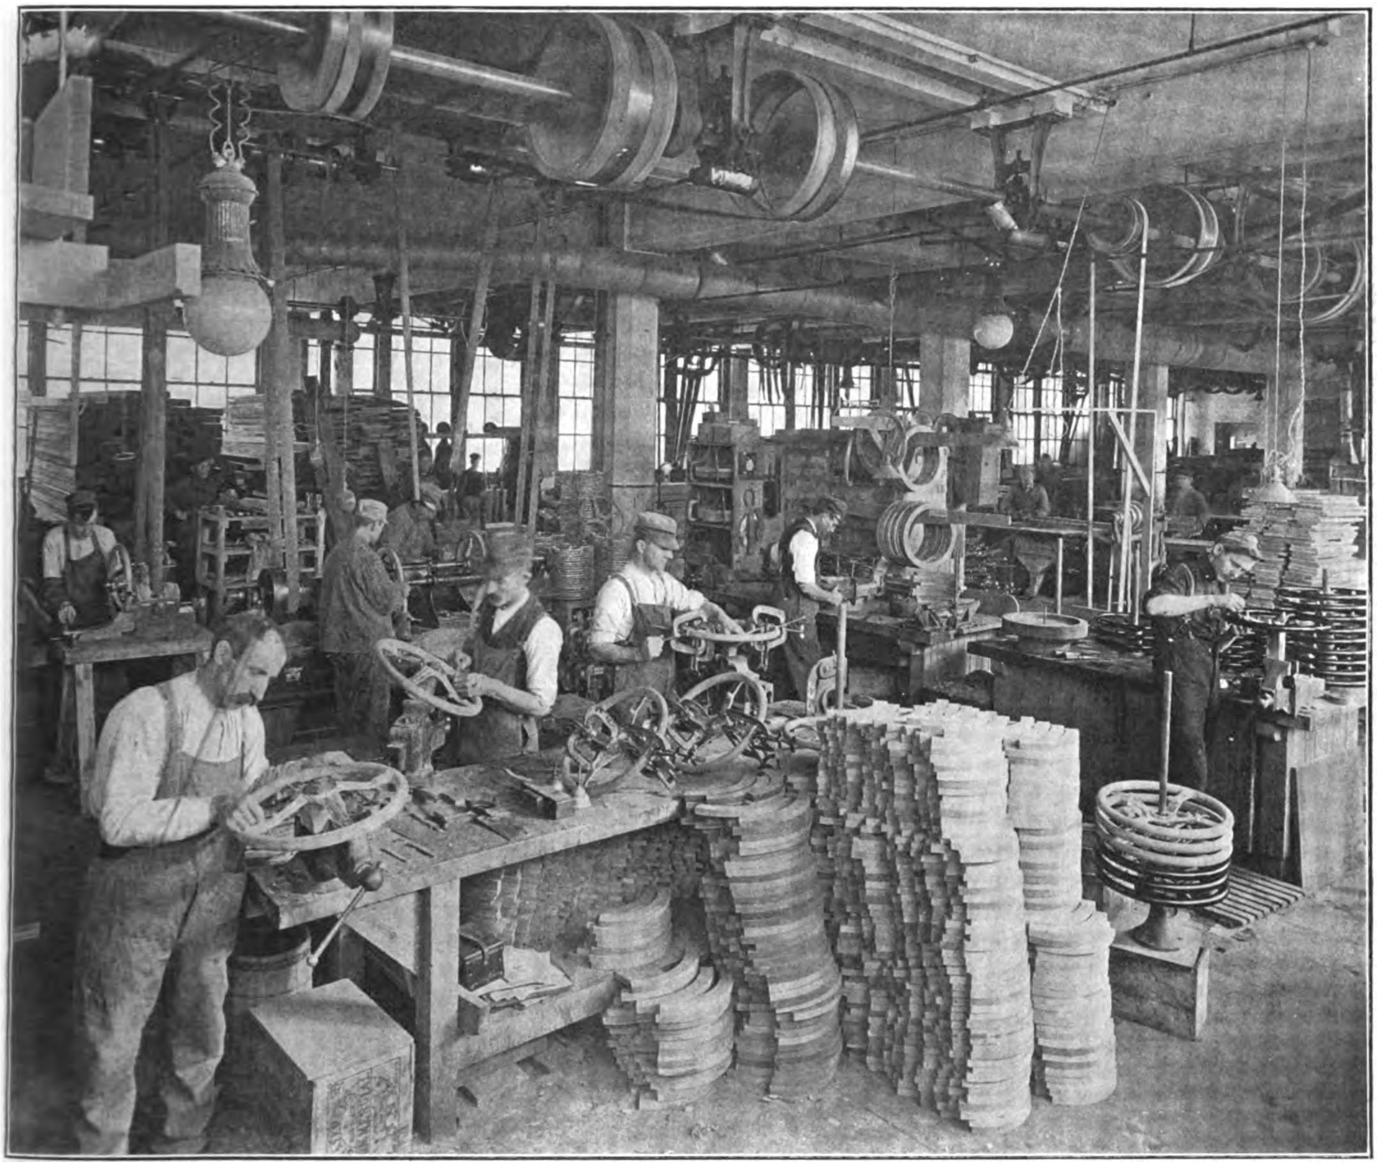
The first step in the transmission is a single chain from the motor shaft to a countershaft midway on the length of the car. Tension of the chain is varied by altering the position of the motor, and for this purpose a broad wooden wedge is carried between the rear of the crankcase and a transverse frame member, and on the movable hangers being slackened off a little the wedge is driven home until the slack of the chain has been taken up.

Two pulleys are mounted on each extremity of the countershaft, and from one of these the drive is taken to the rear wheels by means of V-belts. The second pair of pulleys is of smaller diameter than the set usually employed; thus when heavy work has to be performed a rapid reduction in gear ratio can be made. This change is made possible by the fore-and-aft motion given to the rear axle. It is attached to the rear of inverted semi-elliptic springs shackled at their forward end, and provided with a central seating which can be moved forward or rearward, as desired, by means of a side lever. It is this which also allows of slackening off the belt sufficiently to make the engine run free. The front axle is pivoted on a vertical spindle, with a coil spring for suspension. Steering is by inclined column with connection made to the axle by means of a stranded wire cable wound round a drum on the base of the steering column.

The driver's position is entirely at the rear, directly over the axle. His passenger is carried in a reclining position exactly in the center of the body, and is really provided with a better suspension than can be found on some cars costing ten times the price of the little Bedelia. Being low and covered in by a sheet-metal bonnet, he is thoroughly protected against the wind. The car is built so low that no step is needed to get into it. Its head resistance is very low, and, as can be imagined, its weight is very moderate. Fully equipped for the road the makers state that the car does not scale more than 330 pounds. The combination of long wheelbase and narrow track makes the use of a differential unnecessary. In France the Bedelia is taxed as a motorcycle. Although it has four wheels of 650 mm. diameter its cost of upkeep should not be any higher than that of a two-wheeler.

Among the Makers

ILLUSTRATING THE METHODS OF FASHIONING WOODWORK FOR STEERING WHEELS—DETAILS OF THE DETROIT ELECTRIC FOR 1911—KELSEY BUILDS A MOTORETTE—OVERLANDS FOR 1911



SHOWING PROCESSES IN THE MANUFACTURE OF MAHOGANY RIMS FOR STEERING WHEELS—PACKARD

WOODWORK in automobiles includes second-growth hickory for wheels, mahogany for the rims of steering wheels, dashboards in various effects, ash as it is employed in body framing, and white wood and other varieties of soft wood in body work, not forgetting that chassis frames, in some of the better class of automobiles, notably the Franklin, as well as the Panhard, are fashioned in wood.

That wood is a substantial material is no better illustrated than by the fact that the first chariot wheel of which this civilization has knowledge was made prior to 4000 B. C., and after it was used in service for a time, the length of which history fails to relate, was buried in a mummy pit at Nineveh, where it remained in seclusion until it was uncovered a few years back, and it now rests in a museum in New York. This wheel was examined and photographed by the Editor of THE AUTOMOBILE a few months ago, and the wood is in an excellent state of preservation, although it shows evidences of services once rendered.

Perhaps the most important point in relation to the woodwork in automobiles has to do with the proper selection of the wood that is to be employed. It is not true that there is any material shortage in the supply of second-growth hickory as it is demanded for use in spokes, but it is true that some of the hurry-up methods employed in the manufacture of wheels are productive of the kind of wheels that should not find an abiding place in automobiles. In Missouri, where second-growth hickory may be found in abundance, which State is now relied upon by the wheel-making industry to supply the demand for this character of wood, the natives are skilled in the art of felling the trees at the proper season of the year, *i. e.*, in the winter time. They are conversant with the good that comes if the wood is cut into suitable lengths and corded there to be left until it is nature-seasoned, and thereafter to be shipped to the plants wherein it undergoes further culling, and the best selections are fashioned into spokes and felloes. But in the mad desire on the part of those who care little for quality to put in an appearance of furnishing much for little without really doing so, all these necessary methods of procedure are short cut, and the wood is shipped as it is felled in the green state, after which it is thrust into a seasoning oven, or, better yet, subjected to a kiln-drying process and the life is baked out of it.

Wheels thus produced offer dangers to the autoist; they collapse on a curve when the speed is high, but even if they do eke out a precarious existence, as it were, they creak and groan under the load, so that the autoist, who is so unfortunate as to pay good money for the car so made, groans too.

Fortunately, this practice is being discountenanced by the makers of automobiles of pretense, and rather than put up with the damaging association with half-baked wheels from poorly selected wood, they are installing their own wheel-making plants, and selecting the wood with care and discrimination. In the meantime the purchasing public finds itself confronted by a coat of paint, shielding the good wheel and the bad wheel equally. How is the purchaser to know the difference between the two? Perhaps the reputation of the company that makes the car will be as good as the woodwork that is used in the wheels of its product.

In this connection it is interesting to note that wire wheels have gained great favor in England. Quite a few manufacturers fit their car as a standard equipment with wire detachable wheels. The claim of the makers of these wheels is that they will stand greater side strains than those made of wood. The other advantage of these wheels is that a spare can be carried, doing away with detachable rims. The spokes are fitted tangentially.

Detroit Electrics for 1911

MODEL P IS A ROADSTER TYPE WITH A LOW CENTER OF GRAVITY; MODEL N IS A LARGE FOUR-PASSENGER VICTORIA; MODEL D IS A BROUGHAM

CHIEF among the changes in the Detroit Electrics as manufactured by the Anderson Carriage Company, of Detroit, Mich., is represented in the direct shaft-drive transmission without reduction from chain to gears. Fig. 1, depicting the Model P Roadster type, is an excellent illustration of the result showing a low center of gravity with an underslung chassis frame, large diameter road wheels and other evidences of progress. This car has an 86-inch wheelbase, half elliptic springs front and rear and the Edison battery is placed under the bonnet in front, making the same quite as get-at-able as a motor in gasoline work. In fine, the general construction of this new model has all the earmarks of the gasoline car, and the body, with its fore-door construction and high superstructure, conforms to the newer practice in body work. Back of the seat line the platform is commodious, affording ample room for the carrying of personal baggage, besides a roomy tool box and whatever else the tourist might care to take along.

It is considered of no real value to rate an electrical motor at some specific power; it is more to the point to furnish a motor that will operate at a low fixed loss and deliver power as required under the varying road conditions, limiting the increase in temperature of the hottest part of the motor to some safe point, as 50 degrees centigrade, if the motor is run under certain prescribed conditions, but these are all matters with which the purchaser is but little concerned provided the motor is so designed as to conserve the battery energy and make the radius of useful travel sufficient for the needs.

The electrical equipment, not considering the battery, is made by the Anderson Carriage Company in its own plant, and the problems involved in this portion of the equipment have been brought to such a high state of perfection that there would be no news value in a reiteration of the well-known facts regarding the established quality of electric motors for vehicle work, particularly when they are produced for a specific purpose such as this.

Edison Battery Is Not Generally Well Understood

After recounting the advances made in the vehicle construction, as shown in Fig. 1, it is more than likely that a discussion of the characteristics of the Edison Battery which is used in Detroit Electrics will be of the greatest interest. In presenting a type of car along lines as indicated in Model P the company has in mind the idea of affording to its clientèle the advantages which are so well appreciated as being present in electric vehicles, supplemented by the further advantage of increased radius of travel and decreased battery depreciation, insofar as the state of the art will permit.

Those who have experience with electric vehicles are perfectly alive to the fact that average per-

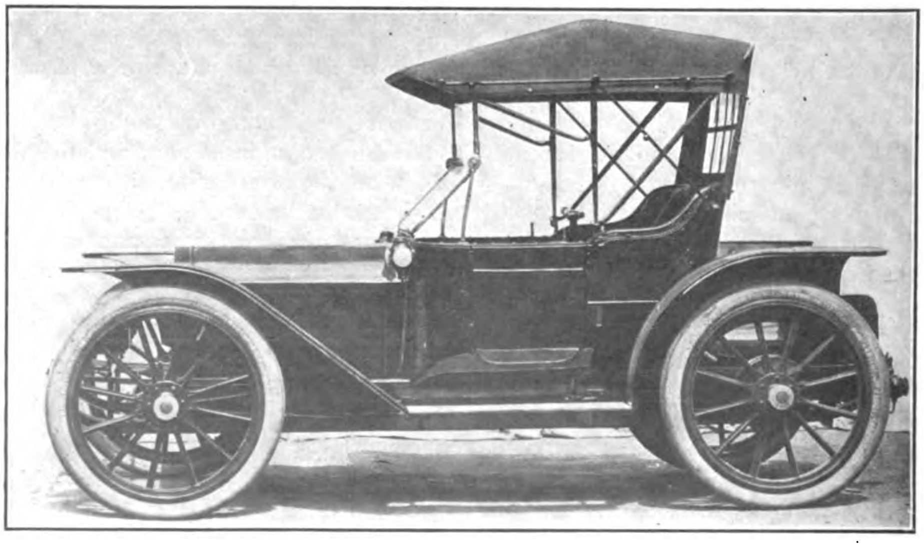


Fig. 1—Model P, Roadster type of Detroit Electric

formance of the battery is more to the point than anything that can be said involving initial radius of travel. In the past it has been found that increasing the initial radius of action was decidedly at the expense of average radius of travel. By radius of travel is meant the distance that a vehicle will travel and be able to come back on the same charge; the actual miles traveled would therefore have to be double the radius of travel. Initial radius of travel is, of course, the radius of action with a new battery; average radius of travel will therefore be the average result obtained during the useful life of the battery. In the earlier efforts along these lines it was found that the battery with the greatest initial output had the shortest life; under these conditions it was, of course, self-evident that if a battery was made with a large surface and light grids its initial output would be relatively high, but its ability to withstand continuous service was limited by the lack of stability of the construction. Then, too, there is the question of sulphation. If a battery is prone to sulphate this disorder will creep in in the night-time when the car is standing in the garage as well as in the hours when the car is running on the road. One of the claims for the Edison type of battery, as used in this car, has for its foundation the fact that automatic sulphation is eliminated.

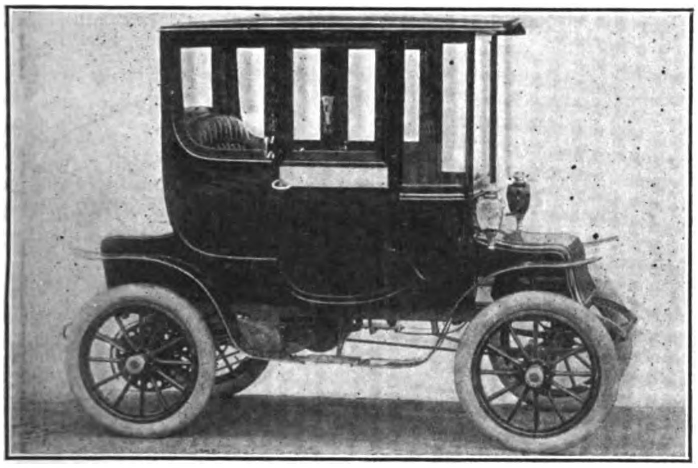

Fig. 2—Detroit Electric Model M Brougham

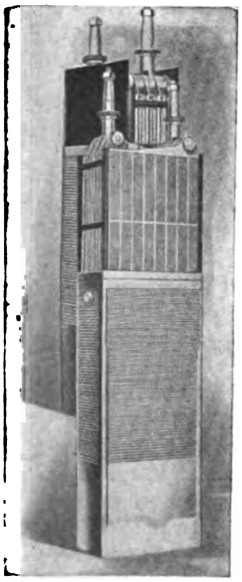

Fig. 3—Type A-4 cell with contents of container partly lifted, showing alternating positive and negative plates assembled

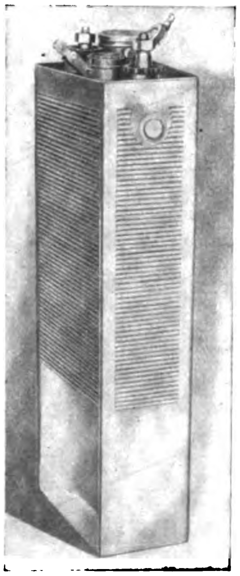

Fig. 4—Cell complete ready to go into a battery of cells

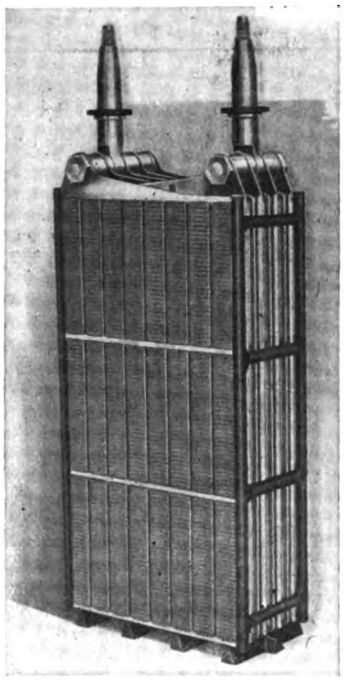

Fig. 5—Showing positive and negative plates of the A-4 cell assembled together, but removed from the container

Fig. 6—Type A-4 cell, showing the positive and negative plates in the container, and also the removed cover with openings

In this form of battery the positive plates consist of steel grids, which are nickel plated; they are in the form of nets of 30 tubes per grid, each of which is filled with active material, the latter being composed of pure metallic nickel in the form of leaves or flakes. The pure nickel flake is produced by an electro-chemical process. The negative plates are composed of 24 flat rectangular pockets which are supported in three horizontal rows in nickel-plated steel grids. These pockets are also formed out of thin nickel-plated steel and they are full of perforations. The active material in the pockets forming the negative element of the battery is oxide of iron.

The positive and negative plates are assembled alternately, as shown in Fig. 6, where they are placed within the containing cell, which is also made of sheet steel. A better idea of the construction of the plates or elements is shown in Fig. 8, with the positive element in the foreground and the negative structure in the background. The capacity of a type A-6 Edison battery is as follows:

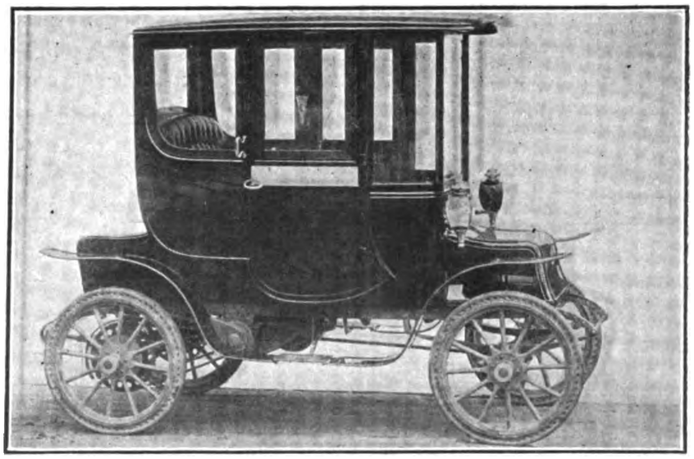

Fig. 7—Detroit Electric Model MS Brougham

CAPACITY OF TYPE A-6 EDISON BATTERY

Charged Seven Hours at 45 Amperes. Discharged at 45 Amperes.

Ampere-hour input	315.0
Ampere-hour output	268.5
Average potential difference of charge	1.692
Average potential difference of discharge	1.202
Watt-hour input	533.0
Watt-hour output	322.7
Ampere-hour efficiency (per cent.)	85.2
Volt efficiency (per cent.)	71.1
Watt-hour efficiency	60.6
Output per pound in watt-hours	16.8

The covers are so designed that the columns of the positive and negative plates pass through stuffing boxes formed in the apertures, the idea being to prevent the electrolyte from spilling out. The liquid which forms the electrolyte is a 21 per cent. solution of caustic potash dissolved in distilled water. This is poured in through an orifice in the cover and a means is provided for rendering the same tight so that the replacement, which is water, will only be that to make up for evaporation, which is at a slow rate.

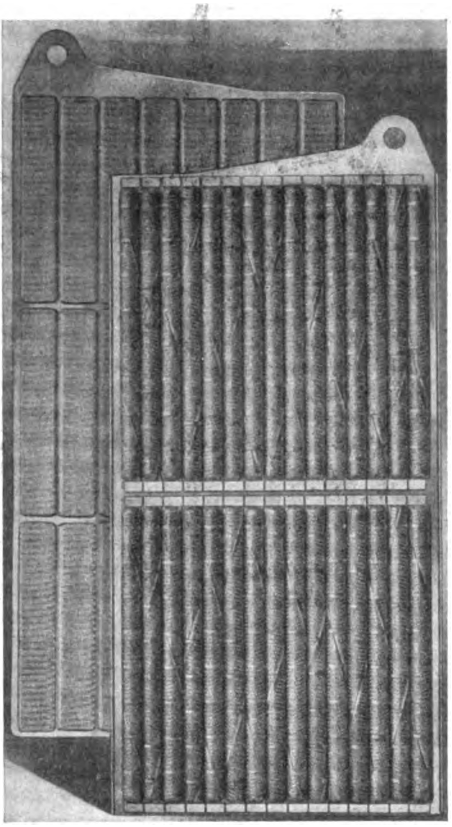

Fig. 8—Type A, positive and negative plates, showing the different structures of each, one tubular and one rectangular

Each cell delivers a mean of 1.3 volts, the maximum open circuit voltage being 1.5 volts, and the range of voltage per cell is between 1.5 volts on open circuit, and 1.11 volts when the cells are said to be discharged. The output of this particular cell is 268 ampere-hours. The battery is made in the several sizes depending upon the service demand, and increasing capacity is afforded by the simple expedient of adding to the number of cells in which the type A-4 has four positive plates and the type A-6 has six positive plates. The method of fastening the plates together is shown in Fig. 5, which is a type A-4 assembly, Fig. 3 being of the same type of cell with the elements partly lifted out of the can or container. The cell complete ready to be assembled into a battery, of which there may be any desired number, is shown in Fig. 4.

It is claimed for this type of battery that it has no deteriorating action, as the tendency to sulphate, and that its life is only reduced the amount represented by normal depreciation which represents an increment of useful work for an increment of life. Electrochemically the battery is in a state of stable equilibrium and when it is in good working order, which is mostly a matter of keeping the electrolyte up to the proper level and giving the battery its full charge, it will remain in this condition until the charge is tapped away in the form of useful work. In view of the stability afforded in the battery the owner of a car is enabled to figure on the radius of travel with much certainty, which is of considerable value to the user of an electric, and the inroads of time are at such a slow rate that satisfaction is a normal expectation.

In addition to the Model P car the company's offering for 1911 includes the Model M Brougham, as shown in Fig. 2, and the Model MS Brougham, as shown in Fig. 7. There are several other offerings and numerous options for purchasers of discrimination; those who prefer the chain drive are permitted to indulge in their whim and if perchance the lead-type of battery is given a preference, it, too, will be supplied to the exclusion of the Edison type of battery.

It is the fair claim of the company that the battery and other equipment used should be in the light of the service to which the vehicle is to be devoted; whim and fancy are not to be indulged in excepting grudgingly if good and sufficient service are prime requisites.

Kelsey Builds Motorette

PRESENTING A NEW TYPE OF GASOLINE MOTORETTE WITH A SINGLE REAR WHEEL WHICH SERVES AS THE TRACTOR

MOTORETTE, so-called, came from abroad and is substantially a reversal of the old tricycle idea in that the single wheel is placed at the rear and is used as a tractor, so that the front portion of the body rests on a conventional type of front axle pivoted on steering knuckles in the conventional way. The tricycle scheme was found to be defective. Cars so made were too easily turned over; a little experimenting, however, resulted in the Motorette, a good example of which is shown in Fig. 1, which is a new product made at the plant of the C. W. Kelsey Manufacturing Company at Hartford, Conn. There are many points of merit residing in this plan of vehicle, and that this situation received early recognition may be known from the fact that Leon Boillé, prior to the introduction of the well-known Leon Boillé type of automobile, took a turn at building motorettes, but the state of the art did not at that time encourage his further efforts.

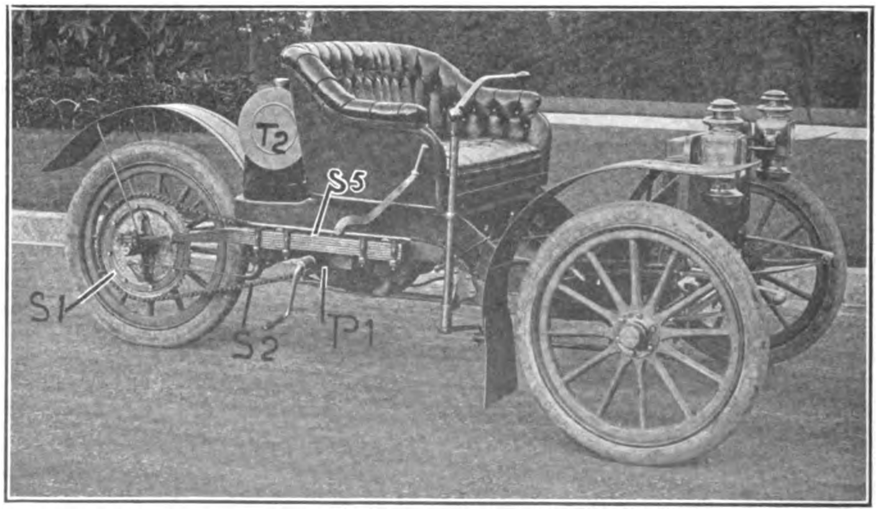

Fig. 1—Side elevation of the Kelsey Motorette, showing the single rear wheel drive and other important details

C. W. Kelsey, president of the C. W. Kelsey Manufacturing Company, while intimately associated with the automobile business along other lines for a number of years, and who will be remembered in connection with the Maxwell-Briscoe Motor Company as sales manager up to a short time ago, built his first three-wheel car as far back as 1897. His trouble then seemed to be due to lack of ability to induce a sufficient measure of lateral stability at the rear end of the car where the frame rested upon one wheel only. Fig. 2 shows how well this phase of the situation is taken care of in the present car, in which T1 is the tractor wheel at the rear of the car, and L1 represents a lever arm which reaches out about 48 inches, so that the turning moment, considering the weight of the man who is standing on the lever, is not far from 9,000 inch-pounds. With this considerable turning moment the sag of the frame at the rear is imperceptible and the tractor wheel remains substantially in the vertical plane. This illustration shows with excellent clearness that the third wheel, serving as a tractor, is also a sufficient support for the rear end of the vehicle. It will be readily appreciated that this form of construction does away with the necessity of using a differential gear for compensating purposes, since there is but one wheel to drive and there is no occasion for compensation. The two front wheels work entirely independent of each other just as they do on conventional types of automobiles, and, of course, they are quite free from the hampering consideration that demands the presence of a differential gear in the makeup of the rear axle of every automobile that uses two wheels for tractive purposes.

A further glance at Fig. 2 will disclose the sprocket wheel S1 fastened to the driving wheel, a side view of which will be found in Fig. 1, S1, and the sprocket pinion P1 is a sufficient distance forward to make the sprocket chain S2 comfortably long. The spring suspension at the rear incorporates the "buckboard" idea, using two flat spring members S3 and S4 (see Fig. 2), a better view of which, including the method of fastening, is given as S5 in Fig. 1. This machine, which will be marketed under the name "Motorette," weighs 475 pounds; the motor is of the double-opposed type in point of design, following along motorcycle lines, and is built self-contained, including a two-speed forward and one reverse planetary gear, which is incorporated in the same housing. The speed of the car is maximum at substantially 30 miles per hour. The construction is such that the ground clearance is 10 inches, and in the management of the car provision is made for careful oiling by a sight-feed system, which, together with other nice features of design, leaves nothing to speculation, nor is the operator in need of over-much skill. The lubricating oil supply and the provision for its use is on a basis of one gallon, and the gasoline supply of six gallons is held in a circular tank T2 back of the seat. This is enough of a supply of fuel to furnish the energy requisite for a travel of 180 miles maximum. The material and workmanship throughout the product are on a carefully worked out basis; Timken roller bearings are used in the rear wheels, and the front axle is of the I-beam section drop-forged from steel. The front spring suspension is of the full-elliptic type and considering the constant loading at the front end the springs are relatively supple so that the road performance is soft and the snubbing action of the springs fits the requirement under the most severe conditions of travel.

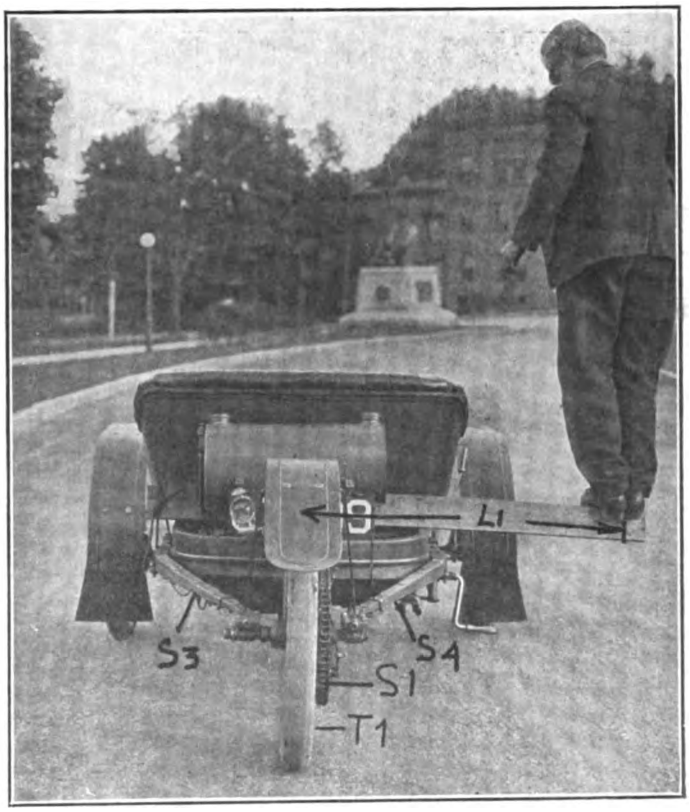

Fig. 2—Rear view of the motorette, showing lateral stability and a flexible spring suspension

The car is fitted with oil lamps, has a tiller steering gear, side lever control, and such other features as would seem to accord with the necessities in view of the character of the work for which motorettes are intended. The price is $385, f.o.b Hartford, and it is the present intention of the company to turn out about 10,000 of these little cars during the next eight months.

Overlands for 1911

SEVERAL NEW MODELS AND MANY REFINEMENTS WILL MARK THE COMING YEAR'S PRODUCT—SLIGHT REDUCTIONS IN THE PRICES OF SOME MODELS ARE ALSO ANNOUNCED

THE Willys-Overland Company, of Toledo, Ohio, are making a bold bid for 1911 business, and are presenting six models of pleasure cars with several types of bodywork. They are built along the lines of last year's models, but some departures have been made and Models 45, 49, 50 and 52 are new, with some distinctive features.

One particular change is that the 1910 model that sold for $1,100 will be sold in 1911 for $1,000, but with three-speed selective transmission will be marketed for $1,095.

The runabout Model 45 is entirely new and is fitted with a four-cylinder motor, 3 1-2 inch bore x 4 1-2 inch stroke, magneto ignition, multiple disc clutch and a low racy or torpedo body. The transmission is of the planetary type and the front axle is an I-section drop forging.

Wheelbase lengths vary from 96 inches in Models 45 and 46 to 118 inches in Models 52, 53 and 54. Models 37 (the delivery wagon), 38 and 49 are 102 inches long; Models 50 and 51, 110 inches, and Models 40, 41 and 42, 112 inches. Fifty-six inches is the standard tread, although there is an option of 60 inches in all models but Nos. 37, 45, 46, 50, 53 and 54.

Tire equipment calls for 34 x 4 front and rear on Models 41, 42, 52, 53 and 54; 34 x 3 1-2 for Models 40, 50 and 51; 32 x 3 1-2 for Models 38 and 49; 32 x 3 for Models 45 and 46, and 33 x 4 for Model 37 (delivery wagon).

Mechanical Refinements in Models 52, 53 and 54

The power plant in Models 52, 53 and 54 is on a common basis, utilizing a four-cylinder, water-cooled motor of the four-cycle type, the general appearance of which is presented in Figs. 4 and 8. Referring to Fig. 4, which is the left-hand side of the motor, the four cylinders C1, C2, C3 and C4 are cast individually of a special grade of close-grain iron, but they are so designed that the amount of finish allowed for in the bore is just sufficient for the intended purpose and the formula of the mixture used in the charge is such that the characteristic of the iron shows a chill tendency, the object being to have the

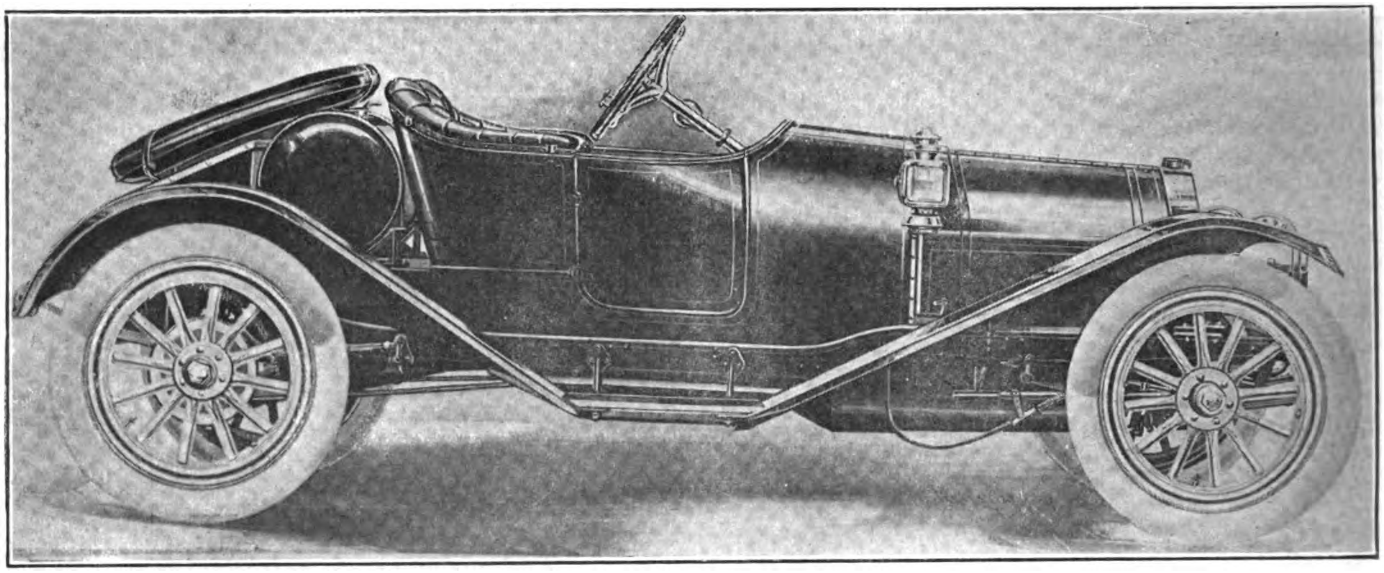

Fig. 1—Presenting Model 53 Overland with an overhanging cowl curved fore-doors, perfectly smooth exterior, a large gasoline supply and a place for the spare tire

finish bore of the character which comes from the presence of white iron, the result being that the walls of the cylinders take on a high polish and besides reducing friction to a minimum as well as inducing longevity, affords no anchorage for carbon formations.

The motor is cooled by the thermo-syphon principle and the back of the radiator shows at R1, with a water box W1 at the top, and a water connection C4, with a suitably designed water manifold M1, with its four legs L1, L2, L3 and L4 of varying lengths to suit the established hydraulic grade. Water connections are made at the top of the cylinders and the allowance for water space over the domes is deep. The refined details of this thermo-syphon system of cooling are in wide contrast with the relatively coarse practice of a year ago.

The greatest difficulty in recent times which bothers the autoist beyond reason and results in an undue cost is involved in the thermic relations as they are governed by the proper utilization of heat units in the fuel on the one hand and the efficacious disposition of the thermic losses on the other. Were it possible to get the average autoist to realize that a single heat unit represents enough energy to lift 142.4 pounds to a height of 1 foot in one minute of time, and that over 80 per cent. of all the heat units represented in the fuel goes to waste, the further task of showing the opportunities for thermic trouble would be much simplified.

At all events there are 20,000 heat units, more or less, in a pound of gasoline. It possesses a greater measure of energy than a pound of nitro-glycerine and it may not be generally understood that substantially 83 per cent. of the composition of this gasoline is nothing more nor less than coal; in other words, carbon. As the demand for fuel increases, the more volatile portion falls short of the requirement and less volatile products are incorporated as a commercial necessity. This reduction of volatility of the fuel coupled with the larger percentage of carbon present, operating under conditions that are a near approach to those that obtain in coke-ovens, leads to carbon trouble in poorly designed motors.

As to the refinements of the motors for use in 1911 Overland cars, the designer recognized the impotency of revamping the main ideas along trodden paths. It is a thermic problem, pure and simple, and with the coming of heavier and less volatile grades of fuel the paramount issue was that of carbon accumulations, it being necessary to solve the mystery of their formation and apply the proper remedy to prevent a continuance of the trouble.

In the older school of motor designing the attention of the expert was riveted on the main point, *i. e.*, power to the exclusion, perhaps, of the questions involving continuity of service. Of course the motor ceases to be valuable to the user when preignition sets in, as it does, due to carbon accumulations, and it was found after some effort that the compression must be fixed, not only to obtain the high thermal efficiency, but also for the purpose of more intimately intermingling the thermal components of the mixture with the oxygen of the atmosphere, of which the mixture is largely composed. Investigation along these lines resulted in determining as to the proper compression to establish, but it was also found that the interior walls of the cylinders as well as the heads of the pistons had to be finished to a high degree and then "buffed" in order to discourage the clinging of the carbon particles to the surfaces.

Glancing again at Fig. 4, the cylinders are cast L-type with a symmetrical exterior, bringing the inlet and exhaust valves to one side so that the exhaust manifold E1 is of graceful design, sweeping back beyond the last cylinder and then down, while the inlet I1 has a stand pipe S1 leading up from the carbureter and from its horizontal portion four branches, B1, B2, B3 and B4, lead to four well-designed transfer ports and thence to the inlet valves, which are of large area and short lift. The method of fastening the manifolds is clearly shown in Fig. 4, there being four yokes, Y1, Y2, Y3 and Y4, spanning the distance between the adjacent branches and serving in common for the intake and ex-

There are eight spark plugs, S1, S2, S3, S4, S5, S6, S7 and S8, inserted in covers over the valves that are utilized in conjunction with the new Bosch "two independent systems" of ignition, which it will be remembered utilizes a Bosch high-tension magneto as the main source of electrical supply and a battery auxiliary which includes a self-starting button, affording adequate protection in the event of the unforeseen and the highest development in magneto ignition service under normal conditions. The wiring system has been planned in the light of modern investigations; it was learned that tubing of any kind utilized as a conduit of high-tension wiring diminishes the efficiency of the system because of the induced effects that are accentuated and distorted when a high potential, high frequency, electromotive force is impressed on an electrical circuit, if the same is in juxtaposition with parallel conductors that are so placed as to set up the phenomena which may be termed condenser effects. True it would be possible to put lightning arresters on improperly designed ignition systems and these devices would tap away the superimposed accumulations from time to time, but such methods lead to additional complication, whereas by resorting to the simple design as here presented the whole series of complex and troublesome tendencies is excluded from the calculation. The high-tension leads are run in the open and are held suspended by

several suitable cleats, one set of which is clearly shown at C6.

In the timing of the valves the principle utilized was on a basis of good and permanent work to the exclusion of the usual multiplicity of small parts and the hazard involved, having for its basis the getting out of adjustment of the one or the other of them. The square valve lifts reciprocate in properly contrived white metal bushings that are broached with square holes. Lubricating oil is prevented from seeping out through the good office of a clever contrivance involving the principle of the closure used in ball-bearing work for the identical purpose. At the outer extremity of the bearing an ante-chamber is allowed for, and the path of flow of the lubricating oil is back into the crank chamber through suitable passage ways with a baffle plate forming the extremity and serving as the heading-off member of the oil flow so that it all goes back into the crankcase instead of out and away. The extensions of the crankcase for the valve-lift bearings are shown at E2, of which there are eight, and at the point of contact of the lifts with the valve stems adjusting nuts are placed so that the timing of the valves may be altered at will.

The other side of the motor as shown in Fig. 8 presents the magneto M1 at a point just in front of the steering gear S1, and the water manifolds W1 and W2 are very clearly shown in this view. If it may be taken for granted that the reader is familiar with the Bosch magneto it will suffice to pass on to important matters of detail since they are among the conspicuous aims of the designer whose ambition is to make this 1911 work satisfactory to the autoist who, with his 1910 experience, would prefer to think that a surfeit of the petty troubles will go into history. Take the spark and throttle control systems as a foundation for discussion. It is pointed out that the universal joint U1 is of a ball and socket type and that the material used is of the true cementing order and the facilities afforded at the plant where the parts are made include an electric-welding equipment, muffle and other suitable furnaces and heat-treatment equipment on an extended basis with means for ascertaining critical and other temperatures.

In the new models that are here being described there will be an entire absence of useless trinkets and misplaced accessories: the running board is confined to its legitimate function and a nice illustration of the innermost thoughts of the designer is shown in Fig. 8; the signal horn S2 is located at a point above the magneto under the hood, with the bell pointed in the direction that the car moves, so arranged as to project the sound wave for a suitable distance ahead. It was found by experiment that the sound wave penetrates for a greater distance when the horn is placed in the manner as here shown than when the horn is placed on the running board, due to the fact that the upward sweep of the mudguards serves as a deflector of sound, so that the wave instead of being projected ahead, where it will do the most good, is reduced to the level of a mere noise which bothers the autoist instead.

Troubles in Operation Promise to Disappear

Every autoist has full knowledge of the fact that in spilling water out of a pail the sheet-like conformation of the stream can thus be induced to flow in through an elongated orifice. This information, while it should have been taken advantage of several years ago, finds a belated response in the newer design as shown in Fig. 10, taking on the form of an elliptically shaped filler F1 of the radiator, with a suitably contrived cover C1 for the same. The design includes limit stops S1 and S2, a means for holding the packing P1 in place and a locking bolt B1, which engages in a depression D1 automatically due to the action of a spring which is concealed in the guide boss G1; when it is desired to throw back the filler cap, pressure is exerted against the spring by applying the same to the handle of the bar H1. In order that foreign substances may not find their way into the radiator a screen is located within the filler F1, but the same is so placed that it may be readily removed, cleaned and replaced, thus offering some inducement to the autoist who desires to minimize his repair bill to keep foreign substances from the cooling system.

Perhaps the most wise provision that has been made in connection with the cooling system on a basis to thwart repair bills lies in the construction of the radiator, the same being formed out of flattened copper tubes lying alongside of each other with intervening spring-like gills that serve as separators. In order to find out whether or not a radiator could be constructed in such a way that it would not be disrupted were the cooling water therein contained to be frozen, the experiment was made with this type of radiator with the gratifying result that the freezing of the water in the tubes ended in a slight expansion of the walls, but as soon as the water was melted, which was a mere matter of running the motor until it afforded the requisite quantity of heat, the spring-like gills compensated for the expansion introduced and the tubes re-formed in their normal position did not show even a tendency to disrupt at any point and form a troublesome leak.

Provision Is Made for Handling Torque of the Motor

Translating the power of a motor is regarded as a difficult task in automobile work on account of the inherent defect that resides in every internal combustion type of motor owing to its relatively poor performance under speed-changing conditions. This lack of holding to a constant power when the speed is varied, coupled to the fact that the motor is irreversible, leads to the necessity of using a clutch to disengage the motor from the transmission at frequent intervals, and of a transmission gear system, by means of which the motor may be permitted to run at a high speed at times when the car must travel at a low speed. The clutch problem has ever been serious, and while many forms of clutches are more or less in vogue, the cone type in its final and protected form as shown (looking from the rear) in Fig. 9 and in perspective in Fig. 5, has few superiors.

Referring to Fig. 5, the power is transmitted from the motor M1, utilizing its functioning methods and equalizing the torque variations by means of a well-contrived flywheel of the minimum weight for the desired effect, the same being flanged to the crankshaft and supported by a large main bearing in the crankcase; but the stresses of the flywheel are resisted by a relatively stout chassis frame with channel section side bars B1 and B2 acting in conjunction with a substantial compound cross-bar C1 with diagonal braces D1 and D2 which not only resist diagonal stresses but serve as supports by means of motor arms A1 and A2 for the rear of the motor. The front end of the motor rests upon a cross-bar at one point only so that the scheme of transmission is three-point suspension. A universal joint is placed just back of the cross-bar C1 in a tight housing H1, the joint proper being shown in detail in Fig. 6. The torque of the motor as it is taken from the flywheel by the cone clutch is picked up by the universal joint and transmitted to the propeller shaft in the housing P1, (Fig. 9) and thence to a three-speed selective and reverse transmission gear which is a unit with the live rear axle. There are some refinements of design and construction to be considered in connection with the combination cross-bar C1, the universal joint as shown (in Fig. 6), the yoke Y1 (Fig. 9) and the other schemes for flexibility as shown in the chassis as a whole. At all events the yoke Y1 (Fig. 9) is related to the cross-bar C1 through flexible mountings M2 and M3, which permit the rear wheels to respond to road inequalities enabling the chassis springs to do their part. The tube T1 and its relating members are free in the vertical plane, but are restrained from lateral travel.

Having thus described the relations of the members and their inter-related functions, reference may now be had to the details of the improved cone clutch. As it is shown in Fig. 9 the housing H2 hides the flywheel from sight but discloses the outer rim of the truncated cone around its periphery P1. Instead of using a stout coil spring as the pressing member for the clutch, three separate springs are utilized, one of which is shown as S1. Glancing at Fig. 5, however, these springs show as S1, S2 and S3, and the locking nut N1 on the stubs over which the springs are placed shows in an accessible position so that adjustment of the springs becomes an easy matter for even the autoist of no ex-

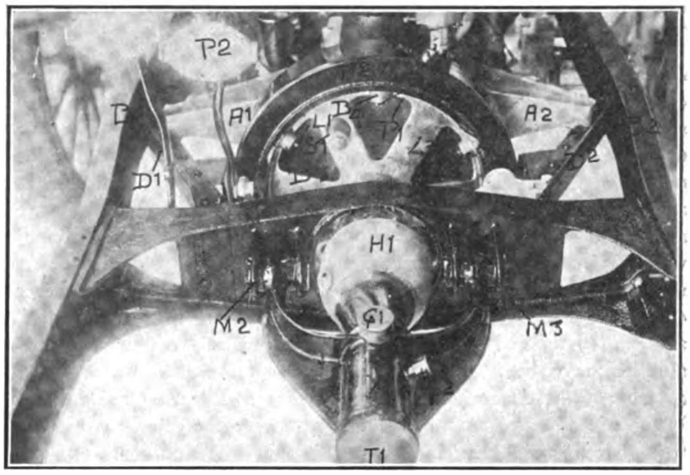

Fig. 9—Looking at the clutching mechanism and universal joint, also the torsion tube yoke and other features of design

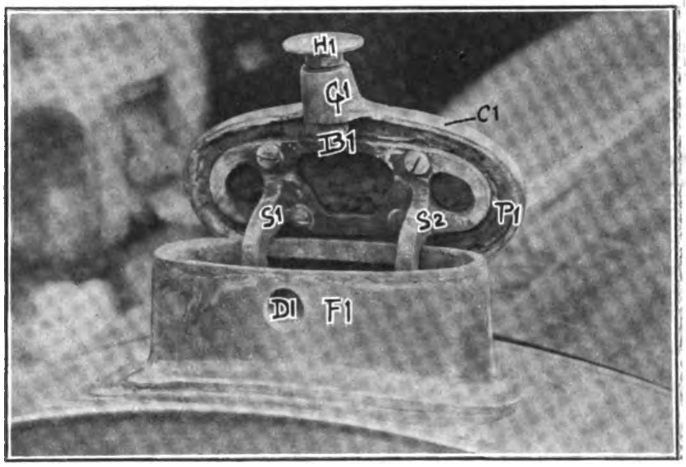

Fig. 10—New form of filler cap on radiator with shape that facilitates filling same, with tight packing and quick release

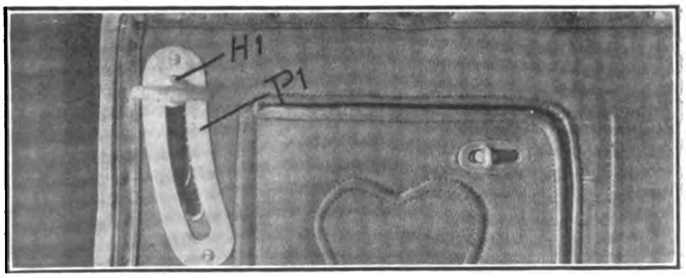

Fig. 11—Detail of the locking method used on the doors, a study of the leather employed and the excellent utilization of pouches

perience. But it is in just such measures for simplicity that trouble hides quite frequently; adjustment of three separate springs by a man of no skill would be an impossibility were it necessary to have the pressure of the respective springs on a balanced basis. Even an autoist of great skill would find it extremely difficult to make just such an adjustment, and in order that this question of the equalization of the pressure might be disregarded the plan includes a rocking yoke which is slipped over a ball-bearing concentric with the crankshaft extension and the extremities of the three arms of this yoke are provided with bosses which accommodate the members over which the springs S1, S2 and S3 are placed. Without going into further detail it will suffice to say that it is a matter of no moment whether or not the pressure on the respective springs is on a basis of equality, since if one spring is given more tension than another, a reaction takes place through the rocking yoke and a part of the excess pressure is transferred to the remaining members and the sum of the pressures of the three springs is accumulated and utilized in pressing the clutch against the conical face of the flywheel.

There are two points that have long been understood as severe strictures against cone clutches. One of these points lies in the flywheel effect, that is due to the diameter, weight and speed of clutches, which flywheel effect makes it extremely difficult to slide the gears in the transmission system, with the result that the gears are battered up and the autoist is reduced to a state of nervous temper that results in abuse to the motor since the gears are not utilized sufficiently for their intended purpose and the motor is overloaded sometimes until it stalls. At frequent intervals this loading to the point where it indicates to the autoist that if he does not slide the gears the motor will stall, this character of abuse offers but slight indication of a future large repair bill, and yet it is one of the most prolific reasons why makers of automobiles have been reluctant to state what would be the percentage of the depreciation of their wares. The first reform lies in the use of an aluminum spider of an extremely light construction, but in order that "spinning" may be reduced a drag brake D1 (Fig. 5) is placed so that it presses against the face of the clutch around the periphery P1, but the shoe of the drag brake is so contrived and fitted into the receptacle R1 that it requires. no attention on the part of the driver of the car. As a further means for introducing delicacy of clutching action and reducing depreciation, six mushrooms are located around the periphery of the clutch, with the heads of the mushrooms pressing out against the facing leather, and the stems thereof are in guides formed in the bosses B3, B4, B5, etc. Under the heads of the mushrooms stiff helical springs are placed and they press against the leather facing exerting 80 pounds pressure. Obviously, this amount of pressure, where there is no limit stop provided, would bulge the leather facing out and prevent the clutch from releasing when it is put through the declutching performance. The particular improvement that eliminates this difficulty is shown in the form of limit stop pins L1, L2 and L3 for each of the stems so that while the springs are capable of exerting 80 pounds each, pressing the mushrooms against the leather, the whole amount of outward travel of the mushrooms is limited to about one-sixteenth of an inch so that the clutch disengages readily and yet the delicacy of the performance is so pronounced that a pressure of less than 20 pounds suffices for the propulsion of the car up a 20 per cent. grade, but the engagement is soft.

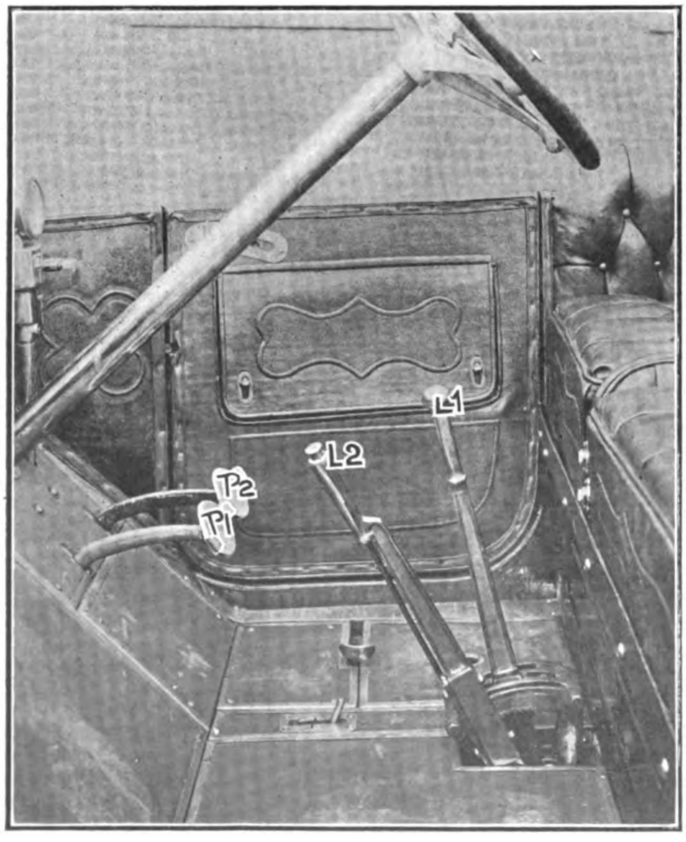

Fig. 12—Looking into the fore part of the body, the left-hand side showing the position of the driver on the right-hand side, free access and the side levers located amidship.

Reference was made to the universal joint as shown in Fig. 6 without calling attention to its refinements. Under ordinary conditions it is assumed that the duty of the universal joint is to transmit the twisting moment of the motor taking up angular positions depending upon the variables of the road surface. It is true perhaps that designers recognized the presence of a third inequality which takes on the form of reciprocating motion and a slip joint is generally utilized to compensate for these fore-and-aft variations.

In the new form of joint as here illustrated the telescoping function is performed by the large fluted member F1 with internal driving extensions E1, E2, E3, of which there are four engaging in slots in the mating member F2, which is also fitted with trunnions T3 and T4, working in bearings formed by a pair of rings R1 and R2, which are clamped together by bolts B1, of which there are eight. The yoke Y1 of the universal joint is integral with the sleeve S1 and the whole mechanism is enclosed in a spherical housing that is rendered oil-tight by means of overlapping joints to unit radius. The whole mechanism is packed in a hard lubricant and provision is made for the addition of lubricating material from time to time. The excellence of this joint in service is partly due to the large bearing surfaces afforded to a considerable extent because the trunnions P1 and P2 are in the same plane as the trunnions P3 and P4.

Intelligent Use of Properly Selected Material

The time has arrived in the building of automobiles when the user expresses a preference for the employment of the best materials for the purpose. It is not now a question of the use of alloy steel indiscriminately; it is important to employ the several grades of selected material that respond to the several demands. Fig. 7 is offered as an illustration of the character of steel that must be employed in the transmission gears if they are to serve efficaciously and last as long as the rest of the car. Fig. 7 shows a pinion that was tested to destruction after it was case-hardened. The crevices to be noted in the surfaces of the case are evidences of the fact that the pinion was subjected to an enormous deflection, but since the case failed to peel off it may be known that the bond between the case and the core was sufficiently tenacious for every possible exigency in service. The best indication of the excellence of this material is shown by the the fact that the hub H1 of the pinion A was subjected to such an enormous pressure that it was displaced more than one-fourth of an inch in the axle plane before destruction. B, Fig. 7, shows a gear blank that was deformed by being put under press until it was buckled over and flattened down. The illustration shows that it stood this abuse very well.

This particular steel has a composition as follows: Carbon, 0.28; chromium, 1.00; vanadium, 0.18; silicon, 0.26; manganese, 0.45; phosphorus, 0.02; sulphur, 0.02. This particular material is good for gear work because it presents a glass-hard surface and is possessed of a kinetic core; moreover, the tenacity with which the case adheres to the core is satisfactory for the purpose.

Fig. 13 represents the method of chassis suspension with a three-quarter elliptic spring at the rear, three U-bolts for clamping of the same, shock absorbers stoutly placed and a substantial gusset plate so formed as to support the action of the spring and transfer the reaction to the chassis frame, delivering the same over a broad area.

Body Work Takes an Advanced Position

Referring to Fig. 12 of a fore-door type of body, the steering wheel is located on the right-hand side, but the side levers are placed amidships. This arrangement permits of utilizing two fore-doors and gives the driver free access to the position of steering on the right-hand side of the car. The sliding gears are manipulated by the side-levers L1, the emergency brake lever is shown as L2, the clutch is manipulated by the pedal P1 and the service brakes are actuated by P2.

Fig. 11 is a detail showing the lock on the doors; it is in the form of the arc of a circle bounded by a plate P1 which serves as a guide for a cross-bar type of handle H1, and when the handle is pressed and its extension traverses the slot the motion thus imparted is communicated to a bar lock and the door is securely held in the closed position or it is released for opening as the case may be, all of which is accomplished without marring the smooth exterior of the torpedo type of body involved. An excellent idea of the fine appearance wrought by thus paying attention to the many details will be apparent by examining Fig. 1 of the Model 53 car. Fig. 2 shows the Model 52 fore-door type of car which seats five passengers, and the chassis of Models 52, 53 and 54 is shown in Fig. 3.

The Overland price proposition is especially favorable, as follows: Model 27, fitted with a two-seated body, sells for $1,000; Model 38, with four-seated body, $1,000; Model 40, 35-horsepower, with two, three or four-seated body, $1,200; Model 41, the same car with five-passenger body, $1,300; Model 42, with selective transmission, five-passenger body, $1,400 (the price of this model last year was $1,500); Model 45, with 96-inch wheelbase, low, two-seated body and gasoline tank at rear, $775; Model 46, the same car with two-seated, torpedo body, $850; Model 49 (the same as Model 37, but has selective transmission), $1,095; Model 50, 30-horsepower, with two-seated body, $1.250; Model 51, same with five-passenger body, $1,250; Model 52, 35-horsepower, wheelbase 118 inches, five-passenger body, $1,600; Model 53, same with two-passenger, torpedo body, $1,600; Model 53, same with four-passenger, torpedo body, $1,675.

Aeroplane Traffic

BY MARIUS C. KRARUP. [CONTINUED FROM LAST WEEK]—THE CHEAP AEROPLANES AND THE PATENTS—PRINCIPAL TYPES OF IMPROVED AEROPLANE MACHINES INDICATED FOR THE IMMEDIATE FUTURE

WHILE there may be dissension with regard to the figures and magnitude of the movement, the preceding analysis of the situation seems to bear out as a reasonable prediction that there is impending a widespread production of small and cheap aeroplanes, and that this production can not be suppressed. And it will be generally agreed without argument that the present development of the costly individual aeroplane, which has already metamorphosed most of the magazines devoted to sports and outdoor life into aeronautical journals and engages from two to ten columns in nearly every issue of the metropolitan dailies, can not be stopped. It must go on in some form. The Alps and the Himalayas, as well as the Atlantic Ocean, must be crossed by the air route before the human mind can declare itself satisfied, once having tasted the delights of jar-less travel through the empyrean and once thoroughly convinced that the physical laws of the universe are friendly and need only be coaxed with a suitable combination of power and insight. If all the aviators tumbled from the skies, one after another, the aviator will still be. *Ruat coelum, impavidum ferient ruinae,* as spoke prophetically Q. H. Flaccus, of ancient memory.

The impending widespread production of small and cheap aeroplanes must rest on the mechanical certainty that it is possible to accomplish at very low cost all that has been accomplished to date at high cost, and even to accomplish, incidentally, a little more, with regard to the safety of the conveyance, than has been offered so far in any one aeroplane machine, and all without exceeding the low cost limit which means popularity.

The coming development of the more elaborate machine, on the other hand, must rest on the necessity for doing much better, the need of much greater safety, much higher speed, much lower speed when required, greater carrying capacity, more comfort; and on the gradual recognition among designers and builders of the proper means to be adopted for these ends. At present, this development must of mental necessity take more than one direction, since all can not at once be made to think alike on the theories of flight, and questions of cost play a subordinate part and exercise little restraint where enthusiasm is coupled with ample means. Judging the immediate future from the immediate past, those who clamor only for more power and fancy that all problems are to be solved by a two-hundred horsepower engine weighing one hundred pounds will not be satisfied till their proposition shall have been tried out to the limit and every propeller shall have become the circumferential part of a rotary engine; and, no doubt, valuable discoveries will be made along the road of these efforts. At the same time, those others who see more deeply important and practical results in first developing the capacity of the aeroplane for slow travel by a minimum of engine power and in the safeguarding of equilibrium by other means than sheer speed, will continue their efforts, and in the course of time these two schools in aviation will meet on the common ground of obedience to the physical laws—obeying them all, rather than picking out some as important and neglecting others—and the costly individual aeroplane will take one or two standardized forms in which the question of high or low speed will be resolved into a question of the payload which the machine must carry. Between the spell of speed and the warning of danger the development will steer itself by degrees toward the final adoption of one type of flier, and the same type will also be reached by a third route through gradual refinement of the cheap flier of the immediate future and the introduction of economical processes for manufacturing the all-around satisfactory design and construction meanwhile and finally evolved for all. In these generalities all may agree. They cover many possible variations of fliers in the interim. It is, however, the sequence and relative degrees of popularity of the first improved types to be developed which is of greatest interest in this attempt at a reasoned forecast of the immediate future.

Before proceeding to specialize in this respect, the possibilities of interference with a rational evolution through the action of special privilege should perhaps be examined. It is frequently asserted that basic patents will greatly retard the whole growth of the aeroplane industry, and, when this is said, it is usually the patent rights of the Wright corporation which the speaker has in mind. The exactions to be expected from this source are not very likely to become burdensome, however, as any demands falling heavily upon each owner of an aeroplane would be difficult to enforce, and the situation seems to be one in which the industry, as such, may slip from under. Probably "means for varying the angles of incidence of the two sides of an aeroplane" are absolutely indispensable for successful flight, but it is at present not generally believed that this indispensable feature can be monopolized except in conjunction with "means for simultaneously controlling the position of a vertical rudder," and the vertical rudder (which is unknown among animated fliers) constitutes only one of many means for effecting side steering. In the case of the simple and cheap aeroplanes, it may be foreseen that any extraordinary financial pressure upon those wishing to engage in the manufacture will simply result in aeroplanes being made without any of the special contrivances which may be subject to tribute, yet so arranged that these contrivances may be added by the purchaser if they are really required, and it does not seem to be excluded that any device which may be desired by the public might be made by separate firms and openly marketed without conflict with anybody's patent rights, since at worst they would not infringe until placed in combination with the aeroplane machine. If the latter, for example, were made sufficiently supple to admit of warping the planes but not equipped with any device for carrying the warping into effect, it would scarcely infringe. And if the aero-supplies stores were to sell cables and pulleys by which such warping might be easily effected and which, if need be, could also be readily connected with the vertical side-steering rudder, if any such be used, it seems evident that the practical burden of possible infringement could be placed upon the more or less intangible or irresponsible purchaser of the plane, and that all legal proceedings would have to be entered against purchasers individually and severally, with the burden of proof as to the actual employment of the infringing combination resting squarely upon the plaintiff. Between the choice of enforcing the demand for a heavy and onerous tribute in a situation as described and, on the other hand, of reducing the tribute to a minimum to which the manufacturers would be glad to submit, and which would nowise retard the evolution of the new industry, there can hardly be a reasonable doubt as to the result, nor as to the justice of it, since after all the practical flying machine is the product of an age rather than of a man, and one in the profits of which the estates of a considerable number of pioneers might well claim certain shares if justice and legality were one and coextensive ideas, particularly so long as the question is of royalties demanded for a construction feature without which no flying can take place. That the feature discovered last among those indispensable attributes of a machine for flying should be worth so much more commercially than those equally indispensable features and proportions discovered by Lilienthal, Penaud, Ader, Langley, Chanute and others seems to be a concession to legality which there is no reason for making more burdensome to the world than it has to be in order that law and order may be maintained.

If the views expressed are reasonable, it may then be assumed that there is nothing in the present patent situation which will prevent the widespread manufacture of cheap aeroplanes suitable for accomplishing all that has so far been accomplished with aeroplanes of any description or cost, and with regard to desirable new improvements it may be taken for granted that whatever will be added in cost of production through their necessity will carry with it corresponding additions to safety and utility, which in turn will result in greater rather than lesser popularity. With regard to the more elaborate and costly industrial aeroplanes, the cost question, as dependent upon the value and validity of patents, is less clear but also less important. Whatever the laws of the land demand in the form of tribute to established rights will be rendered, but it is already apparent that, unless any method for presenting the main planes of a machine at variable angles to the atmospheric resistance shall be considered by the courts as the property of one concern—and this is scarcely claimed to-day to be a probable result of pending litigation—all existing prerogatives will surely be swept into the industrial clearing house where they may be equitably exchanged against one or another of the much greater number of new prerogatives which are bound to be created from time to time in the further improvement of aeroplane construction. The mere fact that the road to industrial perfection of air craft has barely been opened and that commercial results in the end are to be reached by this road only, unless the new manufacture is to be an anomaly in a modern age, precludes the absolute predominance of any one concern, now that thousands are working along the same lines; and the forecast of the probable development may therefore safely be made without reference to the restraining influence of patents.

It should be possible to get a perspective of the prospects by passing in brief review some or all of those facts in the situation which seem to have strongest bearing on the future.

It is known that none of the aeroplanes with whose flight the public is familiar is safe in a turbulent atmosphere. The good paterfamilias whose common sense is extolled in Roman law and held as normal for civilized persons, would not entrust his life to any of them except for very thrifty special cause or in very calm weather. The absence of safety is partly due to lack of natural stability, rendering very quick and skilled control movements necessary in case of disturbance, and partly to the physical impossibility of controlling by rudders unless the machine has speed and this speed (against the surrounding air) is mainly in the direction of the axis of the machine.

The moment cheap aeroplanes are offered the public and give as much safety as the best of the machines now made and exhibited, a much higher degree of safety will be insisted upon in expensive machines. This is a simple commercial law.

Assuming that a safer machine may be constructed, one which a skillful aviator can handle in rough weather, but that the uncertainties arising when the motor is stalled or the aviator gets-confused still remain, a certain demand for a machine of this order may be counted upon, but it will be confined to sportsmen and professional aviators.

If the continued operation of the motor is assured under practically all circumstances, so that a gliding descent to an uncertain landing place will never or very rarely be required, this will in itself mean a considerable reduction in the requirement for special skill and presence of mind, and the circle of possible purchasers must be correspondingly enlarged, but there will still remain a great majority of good fathers of families who will not shoulder the expense of a costly individual machine or the danger incidental to the acquirement of skill in handling it.

In order to enlist this great majority among the supporters of the coming aeroplane industry, it will be necessary to construct and develop a machine possessing all the qualities of the best individual machines and in which the handling may be given into the hands of a skilled conductor whose natural solicitude for his own safety will guarantee that of the passengers. And in order to have flight under these conditions cheap enough to attract large numbers, it will be necessary to have a large structure capable of accommodating as many persons as may be seated in a street car or omnibus.

If a machine of this construction can be turned out, its use will naturally greatly reduce the number of those who will take the cost and risk of even the best individual machine, if the latter can not offer practically the same guarantee of infallible motor power.

Considering that infallible motor power means not only full assurance of having the motor continue to work for the duration of one trip or journey but also the possibility of maintaining it in perfect order without too heavy a draft upon mechanical insight, and that nothing has transpired in motor manufacture, as yet, to warrant the belief that such a motor, of sufficiently light weight, will be produced within the next five or ten years, the whole situation points in the direction of the large or multiple machine with seating and carrying capacity for many, with the safety of the very best individual motor multiplied by coupling a number of such motors together in the same manner as contemplated in the employment of internal-combustion motors for large marine craft, and with the skill of operating the structure, as well as the skill in caring for it, delegated to specialists.

With a view to industrial enlargement of the aeroplane movement, the pressure for profits from expensive constructions must tend in this direction, and this so much more strongly as the experience gained in safe common carriers must act as a powerful stimulus for removing the hesitations which even game sportsmen will naturally feel against investing heavily in individual machines before the sensations accompanying flight under different weather conditions shall have become somewhat familiar to them without the incurrence of heroic risks. In this respect it seems worth noting that the press has very little to say about flights by the many individuals who have bought aeroplanes in France. It is common report that these mostly remain unused in the sheds.

The mechanical objections to all efforts for imparting automatic stability to relatively flimsy machines supporting a relatively heavy weight have been previously noted and are here for brevity's sake omitted.

The hold which the dirigible balloon has upon popular fancy may be mentioned as pointing to the multiple aeroplane as the form of construction which promises the greatest popular participation in aviation and therefore the greatest industrial development.

Among promoters it seems to have become an axiom that any venture which is based upon the amusement of the many has, as such, the best possible chances for financial success, and from this viewpoint there should then be great encouragement for the building of aeroplanes of the multiple type for use at amusement resorts, provided constructions of this order are possible and safe.

While much more might be said on the subject without exhausting it, it is perhaps already made clear that, industrially, the greatest possible stress in the developments of the immediate future should rationally fall in two different directions, first, toward materializing the small cheap aeroplane mostly based upon past experience and established data and, secondly, toward perfecting the multiple aeroplane capable of carrying many with perfect safety.

The main requirement of the moment must then be a construction which lends itself to the latter purpose. And it is clear that lateral enlargement of aeroplanes of the current types is beset with enormous engineering difficulties and increased troubles in maintaining the balance of the structure. It is also clear that longitudinal enlargement is inconsistent with control by rudders, fore or aft. The supporting planes themselves must be the rudders, that is, the wings must be adjustable. A structure with, for example, six pairs of adjustable wings could not

(*Continued on page* 509.)

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL CLIMBS, ETC.

Dec. 1	Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Dec. 31-Jan. 7, '11	New York City, Grand Central Palace, Eleventh Annual International Automobile Show.
Jan 7-14, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Manufacturers.
Jan. 16-21, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4,'11	Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories, Exclusively.
Feb. 6-Feb. 11,'11	Chicago Coliseum, Tenth National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.
Mch. 4-11, 1911	Boston, Mechanics' Building, Ninth Annual Show, Licensed Automobile Dealers' Association.

Races, Hill-Climbs, Etc.

Sept. 24	Belmont Track, Narbeth Race Meet, Norristown Automobile Club.
Sept. 28-30	St. Louis, Mo., Third Annual National Good Roads Convention.
Oct. 1	Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley and Massapequa Sweepstakes.
Oct. 1	Track, Springfield, Ill., State Fair.
Oct. 3	Louisville, Ky., Reliability Run, Louisville Automobile Club.
Oct. 6-8	Santa Anna, Cal., Track Meet.
Oct. 7-8	Los Angeles, Cal., Speedway Meet.
Oct. 8	Philadelphia, Fairmount Park Race, Quaker City Motor Club.
Oct. 14-18	Washington, D. C., Start of Washington Post Reliability Run to Richmond, Va.
Oct. 15	Long Island Motor Parkway, Grand Prize, Automobile Club of America.
Oct. 15-18	Chicago, Ill., Chicago Motor Club's 1,000-Mile Reliability Run.
Oct. 27-29	Dallas, Tex., Track Meet.
Oct.	Exhibition Auto vs. Aeroplane, Dutchess County Fair, Poughkeepsie, N. Y.
Nov. 3-5	Atlanta, Ga., Speedway Meet, Atlanta A. A.
Nov. 5-6	New Orleans, La., Track Meet.
Nov. 10-12-13	San Antonio, Tex., Track Meet.
Nov. 24	Redlands, Cal., Hill Climb.
Nov. 24	Savannah, Ga., Road Race, Savannah Automobile Club.

Foreign Shows and Races

May 1-Oct. 1	Vienna, Austria-Hungary Automobile and Aviation Exposition.
Aug. 1-Sept. 15	French Industrial Vehicle Trials.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

JUST now the automobile business is undergoing crystallization and the men who have the vigor and the red blood in their veins on a basis to permit them to do men's work are acting in an executive capacity with great efficiency.

* * *

AS in every other walk in life, there is bound to be a certain percentage of the actors who do not occupy the center of the stage, nor are they likely to have a large say in the final settlement of the many important details that are now scheduled for action.

* * *

PERHAPS there is a sprinkling of the character of a citizen who expects to get something for nothing; this class of man casts a reflection on a basis of discredit on the industry and he is hard to get rid of.

* * *

FORTUNATELY the foundation of the automobile industry is absolutely sound; the principal affairs are going along smoothly, but here and there a fester spot is being encountered; this condition is somewhat perturbing to the character of man who would shine as a fine weather sailor.

* * *

SCRUTINY discloses the fact that too little attention has been paid to the limiting of overhead charges; true, profits, instead of having been squandered in Europe, were put back into the plants with the expectation that the foundation will be more secure, and so it will.

* * *

THAT the result is just what might have been expected may be readily understood, but there is a slight plaint based upon the theory that the cost of the purse has made heavy inroads on the fund that incumbered a less pretentious hiding place.

* * *

IF there is anything to be said in despair of the automobile business at the present time, it may be summed up in the simple statement of the fact that there may be a little more raw material on hand than would seem to be absolutely necessary in view of the immediate demand for cars.

* * *

ORDERS are coming in steadily; the public persists in believing in the automobile on a utility basis; the banker who wishes to shine as a moulder of public opinion is proving that he is lacking in luster, and the conservative banker who wisely confines his activities to his legitimate sphere is lending real support to the industry.

* * *

HOW to do without the rumor monger who pesters the automobile landscape is a problem that would seem to be hard to solve were it not for the persistence with which the law of the survival of the fittest goes on its serene way.

* * *

NEVERTHELESS, the temptation to maintain that the law is a little rusty on its hinges is stout in many quarters, and certainly it would be to the distinct advantage of the automobile business were those who circulate baseless stories gagged by a spell of real work.

* * *

BUT success is more gratifying if it is seasoned with adversity, and while it is admitted that the peppery ingredients are ever present, it is impossible to hide the splendid measure of success that the automobile business is enjoying, the half of which lies in the ample evidence of growing volume that may be seen on every hand.

* * *

FROM now on it is reasonable to expect that bombast and the gamut of pyrotechnics will occupy a fitting niche in a well-designed and efficient cold storage plant while the real makers of automobiles will render their stagnated materials liquid and entertain solvency as an honored guest.

* * *

THERE is some talk about the restriction of 1911 output, but it is not well founded unless it is amplified: the ban is on hastily-made product; the volume of business as measured in dollars will be greater than it was last year by perhaps one-half.

* * *

THE main chance for making a serious mistake lies in not appreciating the keenness of the automobile public; it knows what it wants; if fore-door types of bodies, for illustration, are better than the other kind, the automobiling public will come to a full realization of the fact and it will go hard with the maker who disagrees with merit and a learned clientèle at the same time.

A.L.A.M. Sues Importers

TAKES AGGRESSIVE STAND AGAINST MORE ALLEGED INFRINGERS OF SELDEN PATENT, ASKING DAMAGES AND SEEKING INJUNCTIONS IN FEDERAL COURT

FOLLOWING the recent progressive steps in the Selden patent litigation, the A. L. A. M. has assumed an aggressive position with relation to further action. Suits for damages and profits arising out of alleged infringements of the Selden Patent and asking for injunctions against eighteen importers and dealers in foreign cars and the Fiat Automobile Company of Poughkeepsie, all of whom are not included within the list of licensees under the patent, have been filed and an additional number has been prepared upon which service has not yet been made.

The recent decree of Judge Hough, of the Federal Circuit Court of Southern New York, was directed mainly against the Ford Motor Company and Panhard and Levassor Company, but the action of the court was suspended in each case, after a bond of $350,000 had been filed by the former and one for $16,000 by the latter company.

While the suits against the defendants named have not been prosecuted to a conclusion, the decree filed by Judge Hough was final as far as three other defendants are concerned and it is in line with that phase of the decree that the present batch of suits is filed.

Under the complaints, the defendants are commanded to answer on or before October 3.

The ultimate hearing of the original suit, which has been appealed to the Court of Appeals, is set for the coming term. An adverse decision to the cause of the A. L. A. M. would overset not only the cases that have been appealed but would also nullify the action taken against the importers in this series of suits and those contemplated in the immediate future.

On the other hand, a decision sustaining the position of the A. L. A. M. would serve to make easy the course of prosecution in these cases.

The announcement is made officially that the A. L. A. M. is preparing another list of makers and dealers against all of whom similar suits will be commenced.

Among the companies that have already been served, with the cars they handle, are the following: S. P. O. Automobile Company (S. P. O.); Itala Import Company (Itala); Albert C. Otto (Saurer trucks); Fiat Automobile Company (Fiat); C. G. V. Import Company (C. G. V.); Delahaye Import Company (Delahaye); Zust Motor Company (Zust); Benz Auto Import Company (Benz); Hotchkiss Import Company (Hotchkiss); Daimler Import Company (Mercedes); Henry Ducasse & Company (Darracq); Renault Frères Selling Branch (Renault); Saurer Motor Trucks (Saurer trucks); Albert C. Travis (Mercedes); Healey & Company (Mercedes); Fiat Company of Poughkeepsie (American Fiat); A. T. Demarest & Company (English Daimler); J. M. Quinby & Co., Newark, N. J. (Isotta).

Wisconsin Court Hears Velie Suit

MILWAUKEE, Sept. 19—The Supreme Court of Wisconsin heard arguments late last week on a motion of the defendants in the $500,000 conspiracy suit brought by the Velie Motor Vehicle Company for a writ of prohibition to prevent Judge W. J. Turner, of the Circuit Court for Milwaukee County, from assuming jurisdiction in the matter. The case was taken under advisement.

Judge Turner recently dismissed the cases against twenty of the defendants by stipulation, holding four, of which number one was subsequently released. The remaining defendants are: Pope Manufacturing Company, Chalmers Motor Company and the Locomobile Company.

These defendants ask for a writ of prohibition, claiming that as service was made upon the Wisconsin sales representatives of these concerns, the foreign concerns have not received legal service of the complaint. The twenty-fifth defendant, the Kopmeier Motor Car Company of Milwaukee, a retail selling agency, is not concerned in the demand for the writ of prohibition. The Kopmeier company's demurrer was recently upheld, halting proceedings temporarily.

Variation in American Automobile Prices Since 1903

The Association of Licensed Automobile Manufacturers has just made public a most interesting tabulation in connection with the industry. It is a chart showing the variation in the average price of motor cars from 1903 until the present time. The reduction shown since 1907 is brought about by the great increase in the manufacture and sale of machines selling at $1,500 or less. The sales recorded by makers licensed under the Selden Patent are for American gasoline automobiles only. By comparison the sales of steam and electric vehicles are small.

The following comparative table indicates the average price for each year, including the first six months of 1910:

1903	Average price	.....$1,133.37	1907	Average price	.....$2,137.56
1904	" "	..... 1,351.45	1908	" "	..... 1,926.94
1905	" "	..... 1,609.79	1909	" "	..... 1,719.93
1906	" "	..... 1,853.93	1910	to July 1st	.... 1,545.93

The Fairmount Park Rac

ONE of the richest prizes, one of the most characteristic of all the American road races and one of the most spectacular and unique events of motordom is the Fairmount Park 200-Mile Road Race of the Quaker City Motor Club, the third renewal of which is scheduled for October 8, one week after the Vanderbilt Cup event has been decided.

The money prizes hung up by the club this year total $6,500 and in addition there are numerous rich awards of plate and cash. The field this year will be divided into five classes under divisions 2, 3, 4, 5 and 6-C, which will allow any gasoline car or chassis made by a factory that has turned out at least 50 cars within the past twelve months, not necessarily of the same model and which measure from 161 to 750 cubic inches piston displacement, without minimum weight restrictions, to enter the race.

As the Vanderbilt Cup entries are restricted to cars measuring from 301 to 600 cubic inches, it will be seen that the field of the Fairmount Park race may include both larger and smaller cars than the ones that try for the Long Island crown.

On the face of the proposition it might seem that the admission of the big racing machines was unfair to those of smaller power, but it should be remembered that the course is exceedingly tortuous and that there are no long straight stretches upon which the big road engines' advantage in power would be emphasized. Then, too, there is a class prize of $1,000 offered in each division for the car that makes the best time in competition with those of similar power.

The entrant that makes the full course in the fastest time will win the grand prize of $2,500, and also its class prize of $1,000 and besides a number of other valuable prizes.

There will be no second, third and fourth money hung up by the club.

On account of the location of the race course, adjacent to the city of Philadelphia with population of over a million and a half, the attendance will undoubtedly be immense. In 1908 the estimated attendance was 400,000 and last year the figures were greatly increased.

With the broadening of the conditions of the race, which has been aimed to bring down a larger field of faster cars than ever before, the interest in the race will be intensified and preparations are being made to provide for a crowd approaching the million mark.

The start of the race will be made at noon and the cars will probably be sent away on 15-second intervals, the same as last year. Under the modified ruling of the Contest Board, the field may consist of thirty cars, and, as the race has filled to the limit on each of the two former occasions, it is to be assumed that the starters will number somewhere near the limit set. Owing to a change in the conditions of the race, which allowed Class C cars to enter instead of Class B, the entries so far have been comparatively few, but they are reported as coming in rapidly now. The entry box will not be declared closed until October 3.

The competing cars are required to make twenty-five circuits of the course, which is approximately eight miles long. The park boulevards over which it is laid are so wide that about two-tenths of a mile per lap can be cut off by hugging the pole all the way. Out in the middle of the road the circuit is exactly eight miles. It may be predicted with confidence that a determined effort to hug the pole will be made.

The history of the event is brief and glorious. In 1908 the race was confined to American-made cars and was won by a Locomobile 40, driven by George Robertson. Last year a Simplex 90, driven by the same pilot, scored a rather easy win from twenty

REPARATIONS FOR THE THIRD ANNUAL RENEWAL F THIS CLASSIC EVENT ARE NOW WELL UNDER AY—FIELD OF ENTRIES WILL BE LARGE

other competitors. The time made in the Fairmount race is never fast as compared with that made on several other road courses. The winners in the past have only approximated 50 miles an hour. This is the result of the winding course, lack of straightaways and the presence of several stiff grades. It is thought that the record for the race will be set at a higher mark this year, some drivers talking of a mile-a-minute speed.

Starting on the level South Concourse, the course takes a sudden shoot down the tortuous Sweet Briar Hill to the level of the Schuylkill at the West River Drive. Then comes a three-mile level, following the windings of the river to Neill Drive, where a left turn up the long grade carries the racers to the high ground on City Line road, and thence by a left turn into Belmont avenue. This broad thoroughfare is followed around the base of George's Hill and thence to the head of the stretch.

The committee of citizens acting with the Quaker City Motor Club and headed by Mayor Reyburn as chairman has extended a formal and cordial invitation to President William H. Taft to be the guest of honor during the race. If the President accepts the invitation he will be met at the Broad Street station and escorted to the course by a civic committee, the First Troop Philadelphia City Cavalry and a squad of police. The grand stand, in which the Presidential box is already being planned, will be situated in West Park, just south of Memorial Hall.

From October 3 until the morning of the race the course will be closed to traffic between the hour of dawn and 7 a. m. so that the contestants may familiarize themselves with the route.

One of the features of the race is the fact that half the receipts are donated to charity. In the past the amount turned over to work of this kind has amounted to about $10,000 a year. The city officials act in intimate conjunction with the officers of the Quaker City Motor Club and Mayor Reyburn, Henry Clay, of the police department, and representatives of the various charitable organizations that enjoy benefits on account of the race and the following delegation of clubmen form the executive committee in charge of the enterprise: Frank Hardart, L. D. Berger, Fred C. Dunlap, A. T. James and G. Hilton Gantert.

The following institutions are beneficiaries and participants in the funds raised on account of the race: Home of the Merciful Saviour for Crippled Children, Playground Committee, Mount Sinai Hospital, St. Mary's Hospital and the Police Pension Fund.

Up to the present, which leaves a margin of eleven days before the closing of the entry box, the entered cars are as follows:

Car	Entrant	Driver
Alco	American Locomotive Co.	H. Y. Grant
Chadwick	Chadwick Engineering Co.	Len Zengle
Chadwick	Chadwick Engineering Co.	Al Mitchell
Benz	Benz Auto Import Co.	George Robertson
Benz	Benz Auto Import Co.	Ed Hearne
Apperson	Apperson Bros. Auto Co.	H. M. Hanshue
Jackson	Jackson Automobile Co.	E. F. Scheifler

The officers who will have charge of the race include the following: Honorary referees, John E. Reyburn and S. M. Butler: representative of the Contest Board, P. D. Folwell: referee, R. E. Ross; judges, Charles J. Swain, L. D. Berger, G. Douglass Bartlett; chief timer, Paul B. Huyette; scorer, W. C. Jackson: starter, G. Hilton Gantert; contest committee, R. E. Ross, G. Hilton Gantert, Fred C. Dunlap, A. T. James, A. E. Maltby, George M. Graham, Paul B. Huyette, Evans Church and Joseph L. Keir; technical committee, Percy C. Colket, C. Stead and Harry A. Lewis; clerk of the course, Joseph L. Keir; announcer, Clarence W. Cranmer and the racing secretary, Harry C. Harbach, secretary of the Quaker City Motor Club, who has charge of all the details of preparation and execution for the event.

Vanderbilt Cars Practice

FAST WORK DONE BY CUP ASPIRANTS AT OPENING OF COURSE. ENTRY LIST NOW CONTAINS TWENTY-TWO CONTESTING AUTOMOBILES

PRELIMINARY practice for the Vanderbilt Cup Race commenced Tuesday morning at dawn over the cup course on Long Island. Prior to the formal practice, the Lozier aspirant was run over the route a few times by Ralph Mulford, but nothing like high speed was attempted as the county roads were not closed at that time.

Five more entries for the Vanderbilt Cup have been received as follows:

Car	Entrant	Driver
Jackson	Jackson Auto Co.	E. F. Scheifler
Corbin	Corbin Motor Veh. Co.	Joseph Matson
Amplex	S. J. Wise & Co.	Walter Jones
National	Poertner M. C. Co.	L. A. Disbrow
Stoddard-Dayton	U. S. Motor Co.	Tobin De Hymel

Total entry list to date, 22 cars

The Mercer entry to be driven by E. H. Sherwood, announced for the Massapequa Sweepstakes, has been transferred to the Wheatly Hills Sweepstakes and a Corbin to be driven by Alvin Maisonville has been entered in the Wheatly Hills. An S. P. O. car, entered by Thomas N. Cook, to be driven by Jean Juhasz, and a Correja, entered by J. Mora Boyle, have been added to the entry list of the Wheatly Hills Sweepstakes. The Abbott Motor Company has entered three cars in the Massapequa Sweepstakes. A Lancia, which will be piloted by William Knipper has been entered in the Massapequa Sweepstakes.

Just at daybreak Tuesday morning, the roar of a racing motor was to be heard off to the westward of the grandstand as A. R. Pardington and a party of officials reached the stand. Presently in the gray dusk a swift-moving drab streak appeared upon the distant hilltop and in another moment the Amplex, two-cycle motor, darted past the stand with throttle and muffler wide and roaring like a lion.

Half a dozen watches snapped as the driver nodded toward the stand and the first official trial of the practice was on.

From the time the Amplex disappeared from view beyond the turn in the Parkway until it had rounded the far turn to the northwest and started back again toward the stand, the barking engine was clearly to be heard. Then for about thirty seconds the sound was lost, only to be picked up again as a throbbing against the eardrums when the machine topped the far hill and headed for the line. With a rush and a swirl like the explosion of machine-gun shells in a thicket, the car passed the stand again.

It seemed as if it must have done remarkably fast time from the amount of noise made and apparent speed, but the watches only showed 11:52 for the circuit. That rate of speed, however, would have proved sufficient to have won in other Vanderbilt Cups if maintained from start to finish.

The next aspirant for speed honors was the Simplex, driven by Mitchell. A broken spring-clip prevented anything sensational in the way of a trial, as the driver eased the car along and made the circuit in 12:18 according to announcement.

The second trial proved the end of the practice for the day, but on Wednesday morning half a dozen of the entered machines will go through their paces. The Benz trio, the two Simplexes, the pair of Marmons, the Apperson, two Corbins and the Lozier are on the ground and ready to commence practice.

The course is patrolled from 5 a. m. to 8 a. m. by a squad of flagmen stationed at every crossing and every doubtful spot on the route. The guards are equipped with a red flag and a white flag. The white means danger to the speeding contestant and the red means danger to the public and safety to the driver.

The course is practically in racing shape. The oil treatment of the county roads this year consisted of 1,500 gallons to the mile and will not be repeated before the race. One good rain is needed to put the roads in ideal condition and the weather appearances favor at least that much precipitation.

The start of the Vanderbilt Cup has been advertised for 5 o'clock sharp, but by October 1 it will be stone black at that hour and it is likely that the first car will not be sent away until about 6 o'clock. The Vanderbilt entries will be dispatched at ten second intervals and one hour after the last of the cars is sent on its long dash, the first of the Wheatley Hills entries will commence its race. After the contestants in that event have started, there will be another lull for a half hour and then the contestants for the Massapequa Sweepstakes will be called to the post. The idea is to hold the interest and attention of the crowd until the finish of the race and to provide a powerful motive for keeping the course clear until practically all the cars in the three events have passed the line.

If the plans work out as intended, it is not unlikely that the winning cars in the three contests will finish in the same lap. This of course contemplates fast time by the Vanderbilt winner, but external appearances seem to favor some exceedingly rapid work in that class.

The telautograph will be used in disseminating information from the stand to the scoreboards, there being one transmitting instrument and seven receivers in process of installation at present. The process of scoring will be augmented by the use of this instrument. The timers will hand the scores to the operator who will send them direct to the board markers. On either side of the press stand giant frames are being built to hold the boards, and the system of marking that will be used allows the operator to place the lap figures in appropriate squares behind the board and without obstructing the view from the grandstand, to display the figures on the face of the board.

The Warner timing instruments will be installed by Friday morning, when it is expected that all the contesting cars will be in camp.

There was a heavy fog over the Vanderbilt Cup course Wednesday morning when day broke and for a short time it looked as if practice would have to be postponed. But about 6:30 o'clock the fog lifted and in a short time one of the Pope-Hartford cars came down to the line with everything drawing alow and aloft and Bert Dingley at the wheel. The racy-looking white car flashed by the timers and was gone in a jiffy proceeding over the full course and finishing the lap in 11:21, which is the fastest time made in practice so far this year.

The Simplex (Mitchell) made a round in 11:41 and the other Pope-Hartford entry was also out. The Marion, entered in the Wheatley Hills, was given a spin by Basle at moderate speed.

Good Roads Convention Draws Interest

Interest in the Third National Good Roads Convention which will assemble in St. Louis, September 28 and remain in session for three days, is as wide as the country. While the proceedings and deliberations will be of more direct value to the Southwest than any other general division, the convention will be attended by big delegations from Massachusetts, Colorado, the Pacific Coast, Gulf Coast States and from nearly every other quarter of the land.

The program includes a series of addresses that will go to the root of road construction of the most advanced type. Among the speakers are the following: N. J. Batchelder, master of the National Grange; Charles S. Barett, president of the Farmers' Union; C. O. Raines, master of the Missouri State Grange; and a dozen other leaders of thought and action on the subject of good highways.

1911 Cars at Detroit

AUTOMOBILE SHOW AT THE MICHIGAN STATE FAIR MARKED BY THE FIRST APPEARANCE OF MANY OF THE COMING YEAR'S MODELS

DETROIT, MICH., Sept. 19—Never, in the history of the Michigan State Fair, has the gasoline motor had such a representation or played so conspicuous a part as this year. The opening of the 1910 fair also marked the opening of the new automobile building, a handsome, two-story brick structure, 125 by 275 feet, with a floor space of more than 68,000 square feet. Nearly all of the space is occupied and the opening found most of the exhibits in place.

Following is a list of the exhibitors:

Security Auto Co., Olds Motor Works, Lion Motor Sales Co., Maxwell-Briscoe-McLeod Co., Ford Motor Co., Anderson Carriage Co., Cadillac Motor Car Co., Detroit Motor Sales Co., Herreshoff Motor Car Co., Brush-Detroit Motor Car Co., Elmore Auto Co., Cartercar Co., J. P. Schneider, Overland Sales Co., Van Dyke Auto Co., Cass Motor Truck Co., Port Huron; Keeler-Hupp Motor Co., Montgomery Motor Sales Co., Winton Motor Carriage Co., Grabowsky Power Wagon Co., Rapid Motor Vehicle Co., Buick Motor Co., Regal Motor Car Co., C. B. Fear, J. H. Brady Auto Co., W. A. Patterson Carriage Co., Flint, Mich.; Standard Oil Co., Atlantic Refining Co., Cleveland; Auto Supply & Manufacturing Co., Searchlight Gas Co., Pittsburg; Auto Equipment Co., Eastern Rock Island Plow Co., Indianapolis; Flint Wagon Co., Gillespie Auto Sales Co., Jackson Motor Co., Jackson, Mich.; Michigan Magneto, Portland Cement, Emil Grossman Co., New York; Manson-Campbell Co., Wayne Oil Tank & Pump Co., Seitz Auto & Transmission Co. and the Craig Auto Co.

Saturday has been set apart as Automobile Day at the fair and a great racing card has been arranged by the Wolverine Automobile Club, which will have full charge of this feature of the big show.

Buick Financed; Nash Is Manager

Definite announcement of the success of the Buick Motor Company in negotiating a loan of $2,500,000 to provide working capital for the coming year's business has been made. Boston capitalists were interested in the financial plans of the company and it is understood that the matter has been arranged on a permanent basis by the sale of bonds rather than by the floating of short time notes or certificates.

The big plant at Flint, which has been shut down, will be run at its full capacity under new management. Charles W. Nash, who has been general superintendent for several years, will be the general manager. The production for 1911 is estimated at 18,000 cars.

Hartford Tire Men in Convention

The three-day conference of the field representatives and branch managers of the Hartford Rubber Works Company terminated in a dinner at the Shoreham at Morris Cove, New Haven. Those present at the convention were: Justus D. Anderson, president; Harry E. Field, vice-president; E. S. Benson, secretary; J. P. Keough, treasurer; C. B. Whittlesey, superintendent of the works; John Shea, master mechanic; Franklin Kesser, sales manager; D. W. Pinney, assistant treasurer, M. C. Stokes, motorcycle tire department; Charles Clark, motor tire department; W. H. Reed and A. E. Martel, solid tire department; Guy Turner, repair department; Fred Appleton shipping department. The following branch managers were present: E. S. Roe, New York; W. H. Barnes, Philadelphia; Charles Langmaid, Boston; O. S. Johnson, Buffalo; P. H. Goodall, Cleveland; H. Severance, Detroit; A. W. Kirk, Atlanta; W. H. Powell, Chicago and the following salesmen: A. D. Cruden, Harry Snyder, E. H. Fahey, and W. Brown, New York; G. D. Niles, L. C. Havener, L. Frohock, Boston; E. H. Johansen, J. R. Hoffman, E. L. Duffie, and H. V. Koons, Philadelphia; S. N. Keller, Buffalo; H. B. McIntosh, Thomas McClurg, Cleveland; J. H. Tompkins, Detroit; P. B. Simmons, H. E. Smith, G. R. Noble, G. H. Wright, W. W. Clark, Chicago; E. S. Edwards, J. Morgan and C. P. Towne, Connecticut.

Commercial Vehicles in New York Run

Under the management of the New York *American*, a commercial vehicle reliability test will be held in the metropolis October 28 and 29. The course of the run will be over various streets of New York and aside from mechanical ability to maintain a fixed schedule of speed, the test will include economy of operation.

Up to date four entries have been made as follows: Morgan, five-ton truck; Gaggenau, seven-ton truck; Garford, two-ton truck and Renault, two-ton truck.

Aeroplane Traffic

(*Continued from page* 503.)

be conceived as of the biplane type. It must be a multiple monoplane with the wings tandem in pairs. In early experiments tandem construction was found ungovernable, but the planes were rigid, the control by rudder. In fact all aeroplanes have been more or less ungovernable in puffs of wind. All types known have at times been bumped off their equilibrium by atmospheric disturbance. Hence the aeroplane of any type, individual or multiple, needs "springs" or "shock absorbers," even though it floats on air. On second thought it is indeed self-evident that a medium which smooth (that is, calm or steady) supports a half-ton as on asphalt or better, will be capable of jolting the same half ton when rough (that is, puffy). The multiple aeroplane must have "springs"; that is, its adjustable wings must have flexible elements in them. These much elongated structures which it is possible to foresee, if the aeroplane is to have a strong industrial future, will have a much improved stability, as the weight and the propeller shaft may be placed considerably below the level of the air resistance, by reason of the elongated shape, in the same manner as with dirigible balloons. And they can not fall endwise by gravitation; no more than a wooden stick can fall endwise unless it is loaded endwise or twirled.

A description of a multiple aeroplane on the plan indicated would be too long for this article, but it is already seen that a construction of this order is wanted for an industrial development and that it presents no difficulties which can not be surmounted the moment control by adjustable wings is realized in practice; in fact, that it is a simpler engineering problem to construct a multiple aeroplane which can be operated with safety than an individual aeroplane of equal merits. As soon as the combination of adjustable main planes with the required strength and the required weight limit shall have reached the practical solution upon which many engineers are working, the multiple aeroplane available for amusement resorts and as a common carrier should for all the reasons mentioned become one of the most conspicuous elements in aeroplane evolution, and the forces tending in this direction seem so strong as to render it reasonable to expect results in a very near future.

Short News From Everywhere

ITEMS CULLED HERE AND THERE FOR QUICK READING—TRADE AND GENERAL INFORMATION

—The Automobile Equipment Company is now handling the Kissel Kar in Baltimore. The firm is located at 2207 Madison avenue.

—The Woods Motor Vehicle Company has established a St. Louis branch, which will be housed in a new building at 425 North Euclid avenue.

—The Cole "30" is being marketed by the Hartford, Conn., Motor Car Company of which G. P. Barinard and W. N. Smith are the prime movers.

—F. Sheffield, of Shaniko, Ore., left for the Hawaiian Islands the past week, where he expects to handle the Winton car in Honolulu and vicinity.

—The Fisk Rubber Company has recently opened new direct factory branches in Providence, R. I.; Rochester, N. Y., and Oakland, Cal. This makes twenty Fisk branches.

—Formal announcement has been made that Will F. Lipman, of Lipman, Wolfe & Company, has bought the Portland Taxicab Company and will reorganize and enlarge the concern.

—The Detroit Auto Dealers' Association has decided on the time for next winter's annual show. The event will be held at the Wayne Gardens, as in the past, the dates being January 15-21.

—The H. W. Johns-Manville Company of New York has opened an office at Atlanta, Ga., which is in charge of W. F. Johns. Another branch office has been located at Rochester, N. Y., in charge of H. P. Domine.

—The Haynes Automobile Company, of New York, has opened a branch office in Newark, N. J., at 261 Halsey street. C. R. Schuyler, who for the past five years has been with the Buick Motor Company, of Newark, is manager.

—The Portland Livestock and Fair Exposition was opened the past week with a monster automobile parade headed by Acting Governor Bowerman and followed by the entire Portland Automobile Club in several hundred handsomely decorated cars.

—At a meeting of the executive committee of the National Gas and Gasoline Engine Trades Association, held at Racine, Wis., arrangements were completed for the next convention of the association to be held in that city, December 12 to 15.

—The Hudson Motor Car Company of Detroit has increased its capital stock from $100,000 to $1,000,000 and the announcement is made that it will divide the major portion of the new issues among the stockholders of record in the shape of a stock dividend.

—Between fifty and one hundred members of the Adcraft Club of Detroit are preparing to motor to Rochester next month, when the advertising affiliations made up from Detroit, Cleveland, Buffalo and Rochester will hold an adfest in the latter city.

—Under the management of Keith L. Goode, an American, who has resided in Paris, France, for 15 years, the Diamond Rubber Company has opened a branch in Paris for the supplying of Diamond tires to Americans motoring abroad and to the French trade.

—The American Locomotive Company has announced that a new model motor truck of five-ton capacity is to be added to the Alco line. The five-ton trucks are expected to be ready for delivery in a few months. The full 1911 Alco line will be announced shortly.

—Announcement has just been made that the Howard Automobile Company, which formerly distributed Buick cars in Oregon through the agency of the Northwest Buick Company, is to establish a branch in Portland for direct distribution. This branch will be under the management of Mel G. Johnson.

—It has been decided by the Pacific Coast Underwriters' Association to discontinue the requirement charging the building rate for automobile risks when it exceeds the automobile rate of 2 1-2 per cent., and to adopt in its place a flat rate of 2 1-2 per cent. for all models of the current calendar year and 3 per cent. for cars of other models.

—The Automatic Windshield Company, of Detroit, was consolidated recently with the Superior Mfg. Company, of Ann Arbor, Mich. This change is only nominal, for the two concerns have really been joined since the organization of the Windshield Company. The Superior Mfg. Co. has done the manufacturing, and the Automatic Windshield Company has been the selling organization.

—The Pope Manufacturing Company has been flooded with acceptances of the company's invitation to the Pope-Hartford owners to be its guests at the Vanderbilt cup race and judging from present indications there will be a big delegation in the Pope camp. Two large tents will be erected at the course for the comfort of those who come and a luncheon will be served by the company.

—The Leominster, Mass., Automobile Club was organized a few nights ago with a charter membership of 57. It has joined the Massachusetts State Association. The following officers were elected: W. H. Chase, president; A. H. Hall, vice-president; Murray C. Damon, secretary-treasurer; George P. Jones, Alfred M. Litch, Charles H. Howe and John Pickering, directors. President Chase was nominated as the representative of the club at the State and national meetings.

—The Worcester Licensed Automobile Dealers' Association, as a result of the recent success in the first out-door auto show held at the New England Fair, is planning to hold during the coming Winter the first indoor automobile show ever held in that city. The scene of the show will be in the new Worcester Auditorium building, now nearing completion and which will have the largest floor space of any hall or building for expositions in New England, with the exception of Mechanics' Hall, Boston.

—The following agencies for the Parry car have been installed recently: Austin Motor Car Company, Austin, Tex.; Auto Exchange, Vicksburg, Miss.; Auto Sales Company, Cleveland, Ohio; Bennett & Covington, Clio, S. C.; E. L. Cooper, Coates, Kan.; Ed. Dickinson, Shreveport, La.; Ellett & Nilson, Bartow, Fla.; Charles L. Fisk, Middletown, Conn.; Hobart Motor Company, Hobart, Okla.; Irving Garage Co., Washington, D. C.; L. S. Mitchell Auto Company, Chattanooga, Tenn.

—J. E. Levi & Company, who have until recently handled the Reo and Premier in Atlanta, have been succeeded by the Reo Motor Distributing Company. This organization has a larger territory, handling the Reo in all of Georgia and part of Alabama. Just how much territory they will handle for the Premier has not been decided as yet. R. C. Smith, vice-president of the company, may also handle the Oakland in some Atlantic Coast States. The officers of the new company are H. E. F. Jones, president; R. O. Smith, vice-president; G. F. Tumlin, secretary and treasurer.

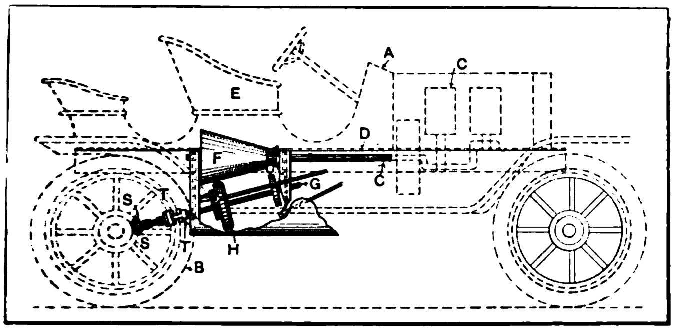
—The Rogers Motor Car Company of Omaha, which has recently begun making motor cars, announces that its plant will be enlarged to a capacity of 5,000 cars annually. The present output of the company is 900 cars a year. C. A. Ralston of Chicago, formerly vice-president, becomes general manager of the company in place of Ralph Rogers, who remains on the board of directors and will be special designer for the company. An addition of brick, three stories high, 300 feet long and 60 feet wide, will be built.

Patents Gone to Issue

DESCRIPTIONS OF A NEW DRIVING GEAR; NOVEL FORM OF WATER JACKET; A SPARK-PLUG—GIVING THE PRINCIPAL CLAIMS FILED IN THE PATENT OFFICE THEREFOR

968,521. DRIVING-GEAR FOR MOTOR VEHICLES. Walter Baird, Pittsburg, Kan. Filed Oct. 24, 1908. Serial No. 459,419 (six claims).

4. The combination, with a vehicle, having a seat, an engine mounted upon the vehicle body in front of said seat, and a conical drum extending into the space beneath said seat and having its smaller end nearest the engine, of means intermediate the engine and drum for driving the drum, a friction roller in contact with the under surface of the conical drum, a driven shaft on which said friction roller is splined, means for shifting said friction roller along said driven shaft, means for moving said shaft toward and from said drum, means for driving the rear wheels of the vehicle from said driven shaft, and a flexible connection in said driven shaft between the friction roller and the means for driving the rear wheels.



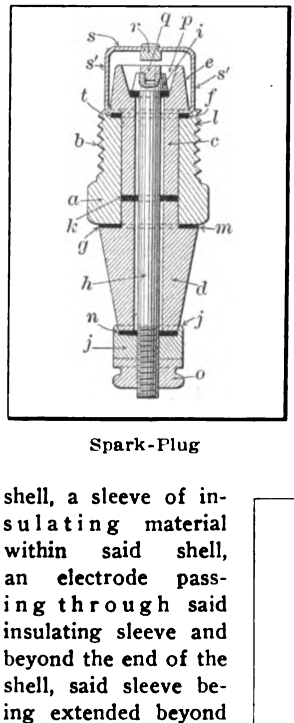
Driving gear for motor vehicles

968,545. WATER JACKET FOR EXPLOSIVE ENGINES. John F. Dodge and Horace E. Dodge, Detroit, Mich. Filed Sept. 1, 1905. Serial No. 276,693. Renewed June 3, 1910. Serial No. 564,854 (six claims).

2. The combination with a cylinder having a flanged head, of a relatively thin sheet metal water jacket embracing the cylinder and having a flat top portion lying upon the flanged head thereof forming a water space between said jacket and the outer wall of the cylinder, a cap having a water space therein and containing a combustion chamber, said cap also having a flat under face which rests upon that portion of the water jacket lying upon the flange of the cylinder head and forming a gasket between said parts, bolts passing through said cap and through the flanged head of the cylinder to clamp the gasket between said cap and flange, the flanged head of the cylinder, the interposed water jacket, and said cap having communicating openings to connect the water spaces of the cap and cylinder, the head of the cylinder and the cap having registering openings to connect the combustion chamber in the cap with the interior of the cylinder, said registering openings last mentioned being counterbored at the juncture of the cylinder head and cap, the gasket portion of the water jacket communicating with said counterbore, a stress ring lying in said counter-bore flush with the inner walls of said parts to close the joint between the cap and cylinder and relieve the gasket portion of the water jacket from strain, and means for detachably securing the lower end of the jacket to the cylinder wall.

5. In an explosive engine, the combination with a plurality of cylinders formed integral and spaced from one another, having a flanged head common to all of said cylinders and spaced from the ends thereof, a sheet-metal water jacket embracing the cylinders and common to all of them, said water jacket having a flanged top portion lying upon the flanged head of the cylinders and co-operating with said flanged head to form a water space at the ends of the cylinders and surrounding the same, said flanged head and top portion of the water jacket lying thereon being apertured to provide for openings communicating with the ends of the cylinders, an integral cap having a plurality of combustion chambers and a flat under face with a plurality of apertures therethrough communicating with said chambers, said cap supported upon the flanged head of the cylinders to confine the top portion of the water jacket between said parts in a manner to cause the apertures therein to register with the openings in the ends of the cylinders, said cap also having a water space therein, and the under face of said cap and the flanged head of the cylinders having registering openings to establish communication between the water spaces in said parts, and bolts passing through the cap and through the flanged head of the cylinders to clamp the top portion of the water jacket between said cap and head.

968,687. SPARK-PLUG. Herbert F. Provandie, Boston, Mass., assignor of one-half to The Randall-Faichney Company, Boston, Mass., a Corporation of Massachusetts. Filed May 18, 1909. Serial No. 496,735. (nine claims).

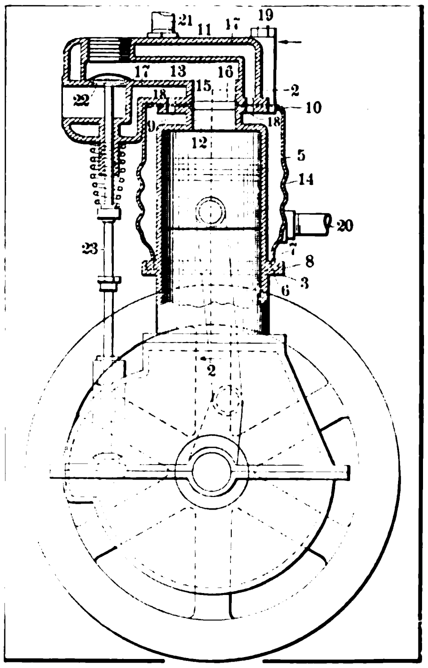


Spark-Plug

1. A spark-plug comprising a shell, a sleeve of insulating material within said shell, an electrode passing through said insulating sleeve and beyond the end of the shell, a head upon said sleeve extending beyond and over the end of the shell and having a recess or cavity containing the electrode end, a metal gasket between said head and the end of the shell, a bridge extending across the end of said head and connected at its ends with said gasket, and a complemental electrode attached to said bridge.

4. A spark plug comprising a shell, a sleeve of insulating material within said shell, an electrode passing through said insulating sleeve and beyond the end of the shell, said sleeve being extended beyond the end of the shell and having a shoulder overlapping the latter, and an electrode bridge crossing the end of the sleeve and having its ends bifurcated to form the halves of a divided ring or gasket and clamped between the said shoulder and the end of the shell.

5. An electrode bridge for spark plugs; a bar with forked ends made approximately as semi-circles.



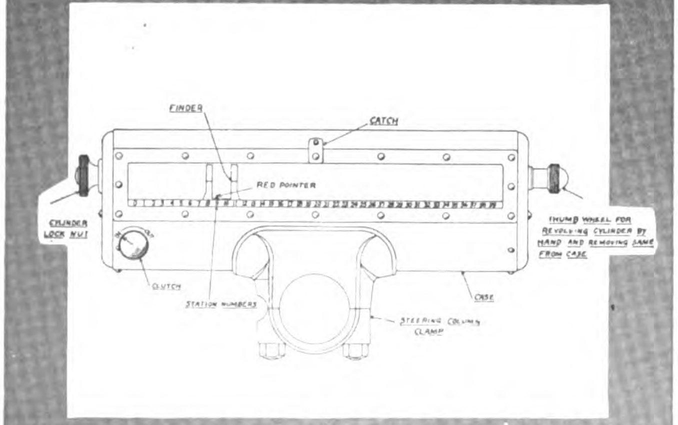
Water jacket for internal combustion engines

Mechanical Touring Guide

THE RHODES PATHFINDER, BASED UPON THE OFFICIAL AUTOMOBILE BLUE BOOK, SHOWS THE WAY BY DAY OR BY NIGHT

The Rhodes Pathfinder Complete

Showing Pathfinder and Cylinder



The Diagram of the Pathfinder

TOURING over unfamiliar roads, without explicit directions as to the course to be followed, detracts materially from the motorist's pleasure. Even the ordinary road-book, consulted under always unfavorable conditions of wind—and sometimes similar conditions of weather—and perhaps in the dark, does not provide the kind of guide that answers satisfactorily when most in demand. Just imagine how convenient it would be to have a native of the territory at the driver's side, giving ample warning of all approaching turns, danger points, exact mileage covered, and such interesting information as the tourists are constantly in need of! To all practical intents and purposes this is just what the Rhodes Pathfinder made by the J. B. Rhodes Co., Kalamazoo, Mich., does—a wonderful little device, contained in a cylinder six inches long and two in diameter!

Based upon the distances and information contained in the Automobile Blue Book, this little director of the movements of a touring party will perform even better than a flesh-and-blood guide—it is "on the job" all the time; never making a haphazard guess as to distances traveled or having its attention diverted by any of the thousand distractions inseparable from an automobile tour. By night or by day it automatically signals the driver, by means of a bell, to be on the lookout for the next turn or guide-mark, danger point or bit of bad going.

Before starting on a day's journey of, say, 150 miles or more—according to the number of directions in the Blue Book—the little instrument should be set for the route. The inner cylinder is removed from its case and the mileage and direction bands, which alternate thereon, arranged in proper order, each mileage band representing five miles and being divided into miles and tenths. Beginning with a direction band, the distance band is set exactly in line therewith, so as to indicate the distance of the first direction from the start. Then the next direction band, with its mating distance band, exactly set, is moved to its proper place on the cylinder, and so on. It takes but a comparatively short time to set the route for the coming day's trip, and replace the cylinder in the outer case, which may be attached either to the dash or on the steering column in easy eye-shot of the driver.

The Pathfinder can be attached to a car that is already equipped with a speedometer or odometer of any make in a very few minutes. Gearing, flexible shaft and full directions for attaching are furnished for cars not so equipped.

After being properly set and affixed to its place on the steering post the Pathfinder will signal the approach of each turn, the little red arrow on the finder pointing to the direction on the band and the mileage showing to the right. A turn of the small knob near the left end of the case throws the Pathfinder in and out of gear, so that side trips from the originally planned route may be taken, or in the event of an obstructed road ahead a detour may be taken and the route resumed farther on.

The key furnished with the instrument is an abbreviated form of the Official Automobile Blue Book, showing only necessary turns and mileages with the proper symbols corresponding to those on the cylinder rings. Many thousands of miles of road directions are thus condensed into a very small compass and the user is assured of every accuracy in view of the fact that all of the routes have been carefully checked by Blue Book cars.

Of course, side trips, optional routes, road descriptions, city and route maps, hotel and garage information and points of local and historic interest are left for the complete editions of the Blue Book, to which this instrument is destined to become an almost indispensable adjunct.

General Utility Electric Motor

HANDY FOR POLISHING AND GRINDING IN THE GARAGE; LIGHTENS WORK OF MISTRESS AND MAID; VENTILATES HOUSE

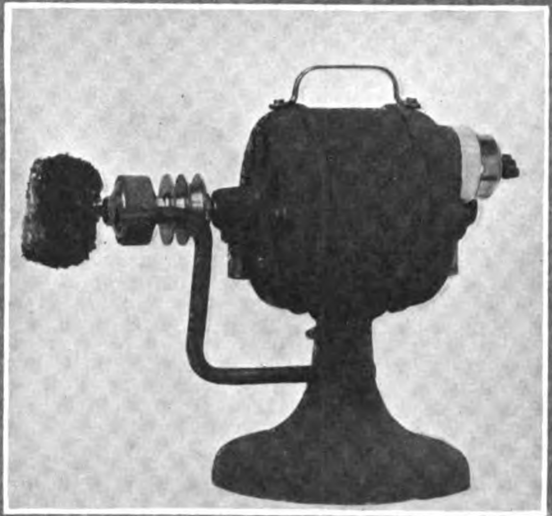
OWNERS of private garages and the "queen of the household"—in the plural number— will hail with delight the advent of the general utility motor now being placed upon the market by the Westinghouse Electric & Manufacturing Company. The numerous little jobs of grinding, buffing and polishing that bob up every day or two in the garage will be made easy of accomplishment through the medium of this compact little motor. The housewife's cares will be considerably lightened by it. It can be attached to the family sewing machine; geared up to a kitchen ventilating blower; it will turn a jeweler's lathe or other light machinery; operate moving window displays or mechanical toys—in short, the varieties of work to which it can be put are too manifold to enumerate.

As the motor takes but from 40 to 120 watts for its operation, it is essentially a day load. In any house fitted with electric lighting conveniences some sort of use can be found for it every day. All that is necessary is to unscrew a bulb and attach the plug to the motor. In the kitchen the polishing of silverware and cutlery will cease to be the *bête noir* of the maid; in the sewing room the mistress or her seamstress may be relieved of the labor of furnishing power for the sewing machine—a full set of attachments being provided by the company for every use to which it may be put. As a ventilating outfit it is especially serviceable. The small blower will remove the odor of cooking from the kitchen and supply fresh air, increase the draft of a furnace or freshen the air of a sick room; and by fitting the blower openings with suitable piping the air currents can be directed wherever desired.

These motors are made for operation on 115- and 230-volt direct-current circuits, and on 110- and 220-volt alternating circuits of 60 and 133 cycles. The direct-current motors are shunt-wound, while the alternating-current motors are of the induction type, single phase. The motors run at a speed of 1700 revolutions per minute. The motor is light and can be easily carried from place to place by means of a handle in the top of the frame. It is artistically finished in black enamel to harmonize with the other house decorations. The applications of the attachments are positive; it is impossible to put them on wrong.

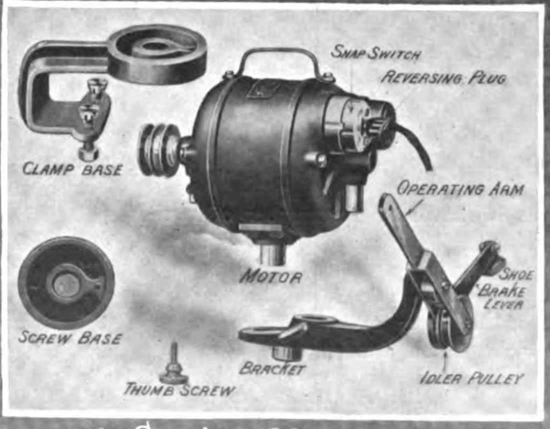
In the ordinary small garage, where the means of storing gasoline are frequently crude in the extreme, the necessity of proper ventilation cannot be too strongly insisted upon. Careless handling of the liquid fuel cannot fail to result in the accumulation of gas, which needs only the lighted match of the smoker or an exposed gas or lamp flame to bring about an explosion. One of these little motors geared up to a small ventilationg blower—providing, of course, the garage is equipped with means of securing the necessary electric current—will clear the air of the dangerous gases in a very few minutes.

The private garage owner whose work-bench is provided with one of these motors will find numerous tasks for the sturdy little engine—running a small lathe; operating, grinding, buffing and polishing wheels for completing home-made repairs on his car, etc.



For Polishing and Grinding

Operating Ventilating Blower



Motor with Sewing Machine Attachments

To Prevent the Loss of Wheel Caps

There are two methods of ensuring that the wheel cap will not come off once properly put on: (1) If the cap screws up flush with the meal ring of the hub a small center punch hole at the point of contact will prevent it coming unscrewed; (2) if the cap overlaps the ring, drill a hole in the ring and in the cap, tap out and place a small set screw that just comes flush with the cap. It will hardly be noticed, but may save trouble and expense later.

Prominent Automobile Accessories

A NEW ROTARY TIRE PUMP

The life of all tires is dependent upon the care with which correct pressures are maintained. It will be found that the majority of people neglect this owing to the physical exertion required, whereas if the labor was reduced they would be more inclined to look after the pressure.

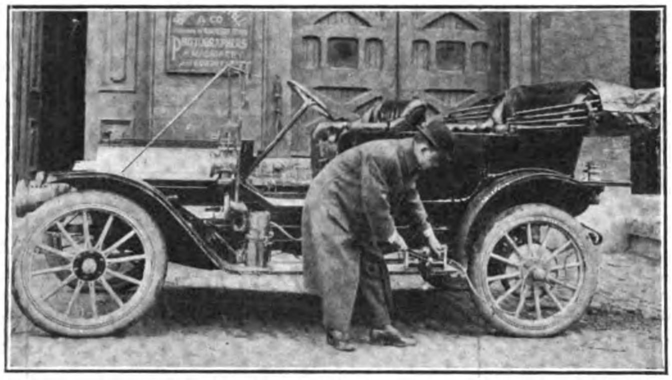


Fig. 1—Inflating a tire by means of the Haw-Man Pump

The accompanying illustrations show the Haw-Man pump recently placed on the market by the Hawthorne Manufacturing Company, of Bridgeport, Conn. It consists of a four-cylinder hand air inflator operated by a handle, the action of which is much less fatiguing than that of the up-and-down plunger variety. It can easily be attached to the running board, and as there is 6 feet of tubing, both rear and front tires can be inflated from the same position.

Fig. 1 shows the pump in position on the footboard, the operator being engaged in inflating the left rear tire. Fig. 2 gives a good idea of the appearance of the rotary pump and the method of its operation.

AUTOMATIC CLUTCH RELEASER FOR BUICKS

The F. B. automatic clutch releaser (Fig. 3), made by the F. B. Co., of Columbia, S. C., is a device to permit the Model 10 Buick being controlled entirely by the foot pedals, dispensing with the high-speed lever. It consists of a turn-buckle rod for interlocking the high-speed clutch and service brake of the high- and low-speed clutches. The method of fitting is very simple and when properly adjusted the device works well, as is shown by the number of testimonials the F. B. Company has received.

Quarter-inch holes are drilled in the low-speed and engine-brake levers as near the front of the lever as possible and about 1 1-4 inches below attachment of long coil spring. Rod 4 requires a little filing to accommodate loops 6, which are simply slipped over the yoke. The sheet-metal round lever 1 has to be cut away sufficiently to allow the two loops free movement.

A slight pressure on the brake pedal throws out the clutch and when the pressure is released the high engages. Heavy pressure on the brake pedal stops the car as when no releaser is used. Slight pressure on the low-speed pedal releases the high speed and operates the low, so that to come back to high all that is necessary is to release the low pedal.

The releaser never pulls the high-speed clutch out to the point where it locks, as does the regular equipment of the car, so that when the high is locked out by hand and the clutch releasers are in use the brake or low-speed clutch may be used independently.

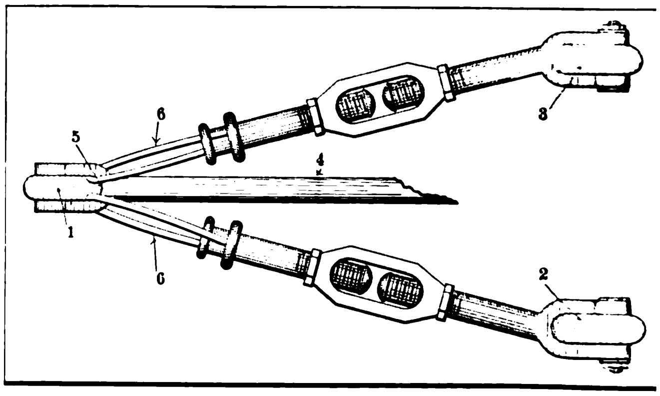

Fig. 3—The F. B. automatic clutch releaser

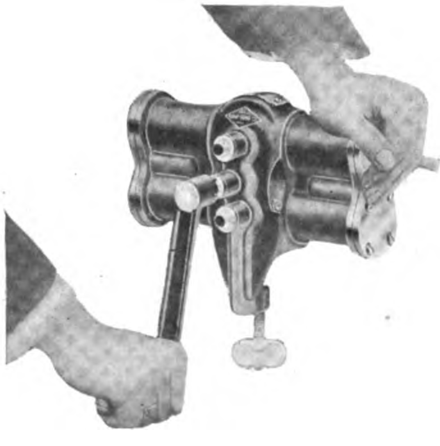

Fig. 2—View of Haw-Man rotary tire pump

LONG- AND SHORT-DISTANCE SIGNAL

The tendency of the times is to reduce the number of accessories necessary to the satisfactory operation of the automobile. The necessity of carrying two warning signals—one for long-distance or emergency warning, another for short-range use—has long been looked upon with disfavor. With the introduction of the "Combination Klaxon," the Lovell-McConnell Manufacturing Company not only effectually meets this objection but provides an instrument (see Fig. 4) which is entirely unique among automobile accessories, and one which will appeal to the motorist.

This signal unites the regular Klaxon with a reed horn of finest workmanship an highest quality.

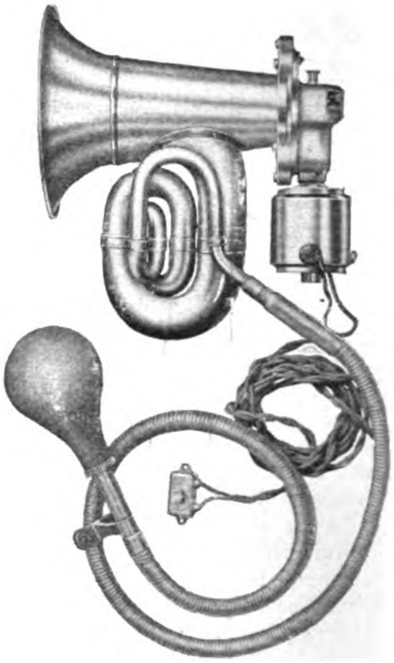

Fig. 4—The combination Klaxon horn

The ease by which either of the two signals may be operated is a distinct advantage. Button and bulb, side by side, enabl the motorist to choose the signal he prefer to use, with the least possible distractio from the operating of the car.

WATERPROOF AUTO GARMENTS

With the approach of the inclement sea son the autoist will be interested in th announcement of the Rubbinol Raincoa Company, 1777 Broadway, New York, th it is prepared to furnish Rubbinol coat capes, leg protectors, sleeve protectors, ca hoods, gloves, etc., and other garments de signed to make winter driving less of hardship, at its usual low rates.

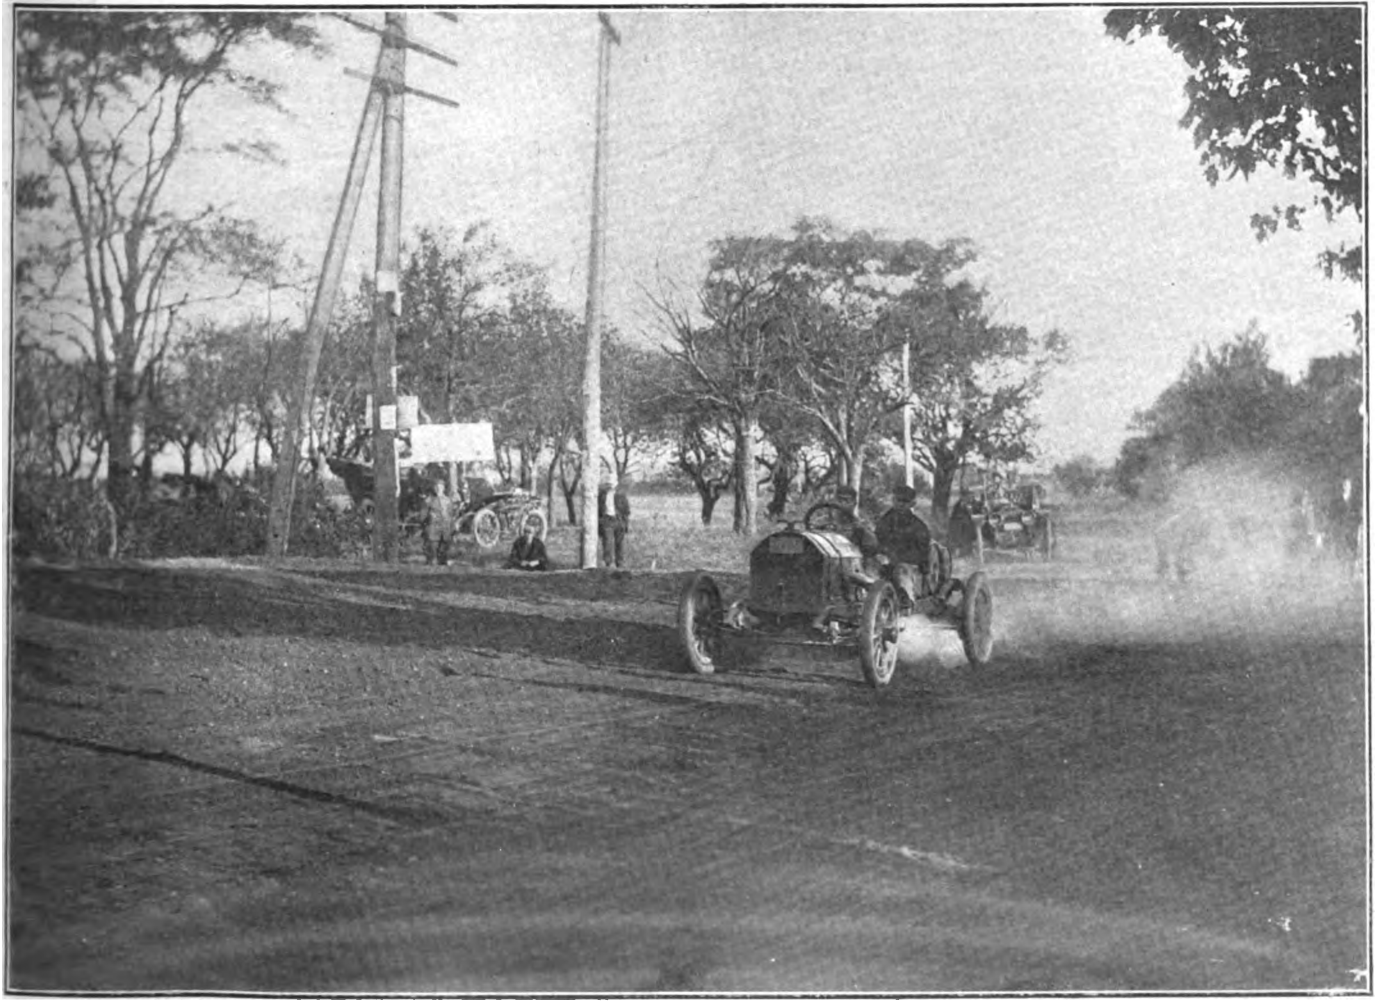
VOL. XXIII NEW YORK—THURSDAY, SEPTEMBER 29, 1910—CHICAGO No. 13

THE AUTOMOBILE

Await Starting Gun

LARGEST AND MOST VARIED FIELD IN HISTORY OF ROAD RACING READY FOR THE WORD IN VANDERBILT CUP AND ITS SHORTER AUXILIARIES

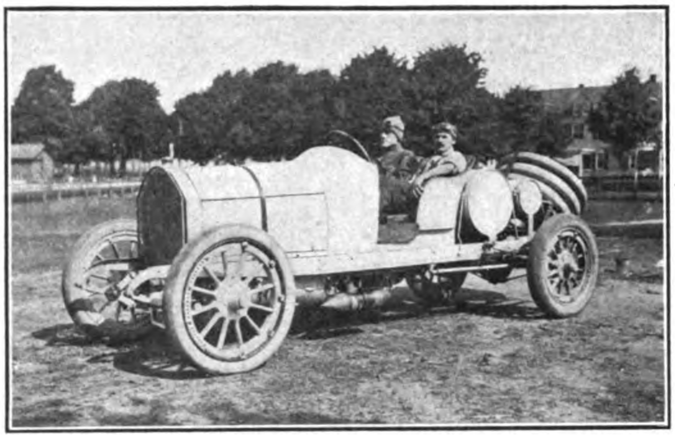
WITH an entry list never approached in point of size and variety, the Vanderbilt Cup race, the Wheatley Hills Sweepstakes and the Massapequa Sweepstakes closed Saturday night. At some stages of the running next Saturday over forty racing cars will be on the track at the same time.



CUP CONTESTANT PRACTICING ON THE WESTBURY TURN JUST BEFORE OPENING THE ROADS TO TRAFFIC

The entry lists contain the very cream and the rich milk of the American racing machines, and the Benz, Mercedes, Lancia and S. P. O. cars, which will represent foreign types in the contests, [illegible] well proven and rank with the speediest cars of the old [illegible] American automobiles are classy. The Alco entry won its spurs on the Vanderbilt course and has proved itself to be a worthy representative of the six-cylinder idea in racing. The Pope-Hartford cars entered for the cup are racy-looking automobiles with long white bodies of the torpedo type, but finished off with a pyramid-shaped dustguard, which reduces wind pressure to a minimum. The National trio are machines that have won time and again on track, road and hill and will undoubtedly give a good account of themselves. The Lozier entry is the same car that won the National Stock Car Championship at Elgin.

The Simplex pair are well known for past performances and either has sufficient speed to lower the existing record for the



Businesslike Benz Car 3 ready for morning trial

Where Vanderbilt and Grand Prize Benzes are quartered

race even though the fortunes of racing might decree that neither should prove to be first over the tape. The three Marquette-Buicks have giant motors and great strength. Piloted by three veterans these cars are certain to be prominent in some stages of the race and will have to be considered in making calculations on the probable winner. The Apperson has won so often on the Pacific Coast that the Western contingent hold high hopes of its performance in the premier race. The Marmon couple, handled by a pair of wizards, have a gallant flight of speed and great endurance and have shown both on many a hard fought field. At Indianapolis and Atlanta on the speedways there were no racing automobiles with a license to treat this pair without consideration. The Jackson entry is a fast car with plenty of bottom; the Corbin is rather an unknown quantity in events of this kind, but from the fact that it will be handled by a particularly skilled driver, the performance of the car will be watched intensely by thousands. The Amplex is another unfamiliar name in racing events of the Vanderbilt Cup type, but the car has shown unusual power and a clean pair of heels in its practice work. The Stoddard-Dayton pair, one of which is the car that swept the boards at the Galveston, Tex., beach meet, are qualified to try conclusions with any kind of automobile entered for the cup. The Knox entry is the same car that Mr. Belcher has driven in numerous hill climbs and races this year and is sturdily able to give a good account of itself. The Oldsmobile pair, entered at a late stage, are very long-rangy looking cars, equipped with big motors and possessing brilliant speed. It has been a long time since the Oldsmobile has tried conclusions in road racing, but, judging from the past, there is no apparent reason why these cars should not be there or thereabouts at the finish. The Houpt-Rockwell car is a big powerful automobile and has been seen in distance races around New York on frequent occasions during the past season.

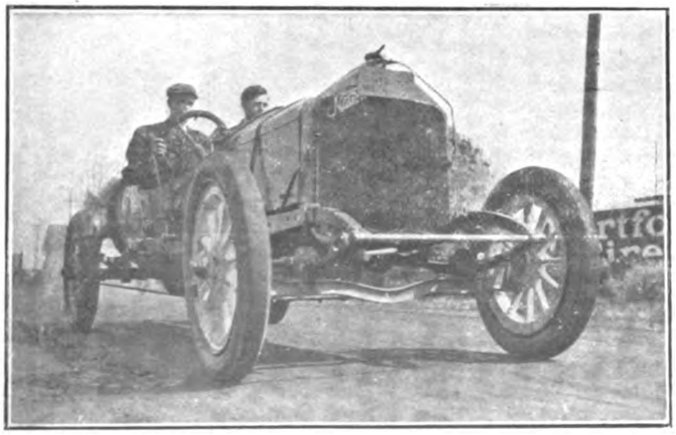
The Benz trio are built from the ground up. They have about as much power as the biggest machines entered for the contest and truly represent the last word of German construction. Their motors have a drumlike sound when in action that bespeaks power and their action is of watchlike precision and nicety. The Mercedes entered by Mr. Wishard is an old car, having been built in 1905. That it has power and speed and stability has been amply demonstrated this year in contests, and while it would seem unlikely that this car would win in such company, more unlikely things have happened in racing.

In the Massapequa trophy race the Cole "30" pair, to be driven by Bill and Harry Endicott, have been frequent contenders in racing events this year and are familiar to the public. The Lancia is a typical European racer qualified to enter this class.

The Abbott-Detroit trio which will make a determined bid for victory in this event are business-like looking cars with bodies painted respectively red, white and blue. This is the initial racing event of any moment that these cars have attempted and their progress will be watched with interest.

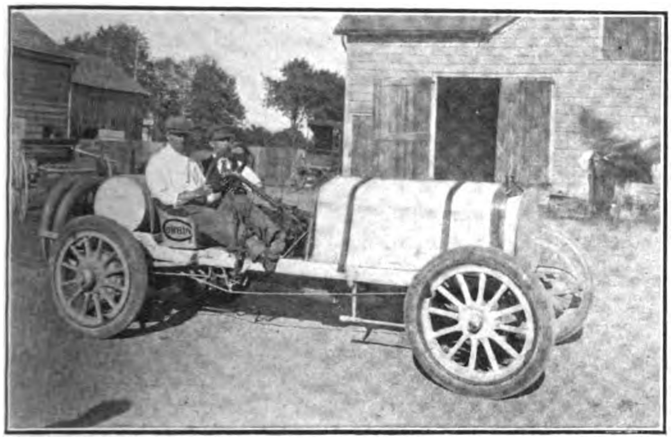
In the Wheatley Hills trophy race there is a Marmon, similar to those entered in the Vanderbilt. Naturally the motor is smaller in order to come within the requirements of the conditions, but otherwise the car is identical with its big racing brothers in the main event. The Marion entry has won dash races and has made a creditable showing in distance events on the track. The Mercer pair have won racing events and have a pretty turn of speed, but their performance on the road-racing field is an unknown factor. The Corbin has done well in reliability runs and has speed and endurance. The S. P. O. entry holds the hour record at Brighton Beach and is a sweet-running, speedy car of French make. The Correja has proved a winner on the hills and is trying the gruelling road race for the first time.

The practice so far has been fast, and of the record-breaking variety. On Friday morning the press representatives of

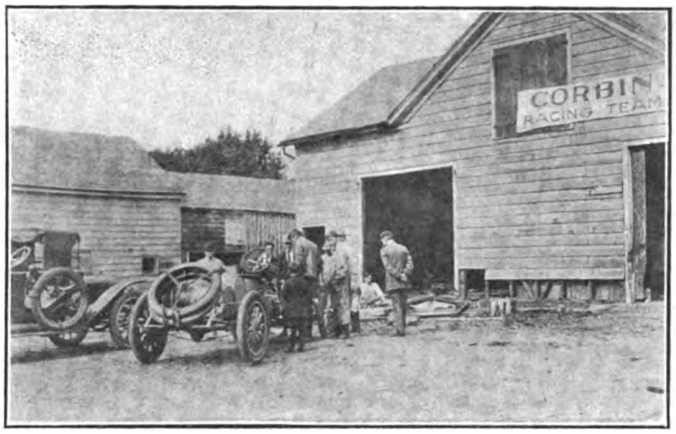


Graceful National Contestant coming head-on along Parkway

Headquarters of the National racing team, showing fast trio



Corbin Cup Car starting for its first spin on the course



Hicksville is the headquarters of the Corbin cars and drivers

New York were invited to be present to witness the first formal spins of the contesting cars. About a dozen were put through their paces. Dingley's Pope-Hartford made the circuit in 10:57.36, the fastest time of the morning. The Warner timing devices were installed Thursday night and the time made has some element of authenticity.

A damper was cast over the crowd by an accident by which it seemed likely that George Robertson, driver of the Benz car No. 1, and his passenger, Stephen Reynolds, of a New York daily newspaper, as well as the car, would be placed permanently out of commission. Robertson had consented to take the newspaperman around the course at speed. Approaching the Massapequa turn, where the course leaves the parkway and swings into the country road, the Benz was traveling at about 65 miles an hour. The turn is banked slightly, but Robertson steered too close to the top and as he realized the danger of going over with the momentum of the heavy car he shut down and tried desperately to stop the car but failed.

The car went over the edge just as Robertson yelled to Reynolds, "it's all off." Rolling over twice, the car righted itself while Reynolds was thrown thirty feet through the air. Witnesses say that Robertson rolled over with the car, but such a thing seems hardly possible. Both men were taken back to the grandstand and recovered consciousness in a few minutes when the driver was removed to the Nassau County Hospital. He was sorely bruised and cut about the face and his right side was jarred; it was feared that he might develop internal injuries. The latest reports from the hospital, however, indicate that his strong constitution and powerful muscular frame have been able to protect him from vital injury and he promises to be on hand for the big race. Mr. Reynolds was only severely shaken and jarred. The car looked to be a wreck, but close examination showed that a few hours' work would put it back in racing condition. After the accident Robertson at first announced that he would positively drive in the race, but later, at the request of his wife, he decided to withdraw. The car, which will be repaired, will probably be piloted by Franz Heim, a German, who formerly acted as a mechanician for Hemery and Hanriot.

The fastest time made in practice on Friday was by Burman in a Marquette-Buick, who turned the course in 10:52.20. Other speedy trials were those of the Pope-Hartford (Fleming), 11 minutes flat; Corbin (Matson), 11:20, on his first trial at the course; Simplex (Mitchell), 11:08; Pope-Hartford (Dingley), 11:14; Benz (Hearne), 13:05; Alco (Grant), 11:14; National (Aitken), 11:29; Marmon (Dawson), 12:18.

Marquette-Buick No. 14, driven by Burman, made the fastest lap ever made in practice over the course on Saturday, when it negotiated the circuit in 10:15, eighteen seconds faster than the best of last year's practice. A good rain has fallen upon the course, rendering it faster and better than ever before, and new record figures for the course seem assured.

The Lancia entry, driven by William Knipper, was wrecked on the Westbury turn Monday morning by collision with Burman's Marquette-Buick. Knipper was hurled into the air, as was his mechanician, but neither was seriously hurt. The car was considerably damaged, but may be repaired in time to take part in the Massapequa race. It is doubtful whether Knipper will be able to drive. The Marquette-Buick, which was in nowise responsible for the accident, was not damaged outside of the loss of a hub cap.

The weighing-in process this year is being conducted at Mineola under the supervision of A. L. McMurtry. The cars for the Vanderbilt only have to be passed upon as to their piston displacement and brakes, but the entries in the sweepstakes are being given a rigid examination.

The Bosch Magneto Company and the Remy Magneto Company have each offered a prize of $500 for the winner of the Vanderbilt Cup.

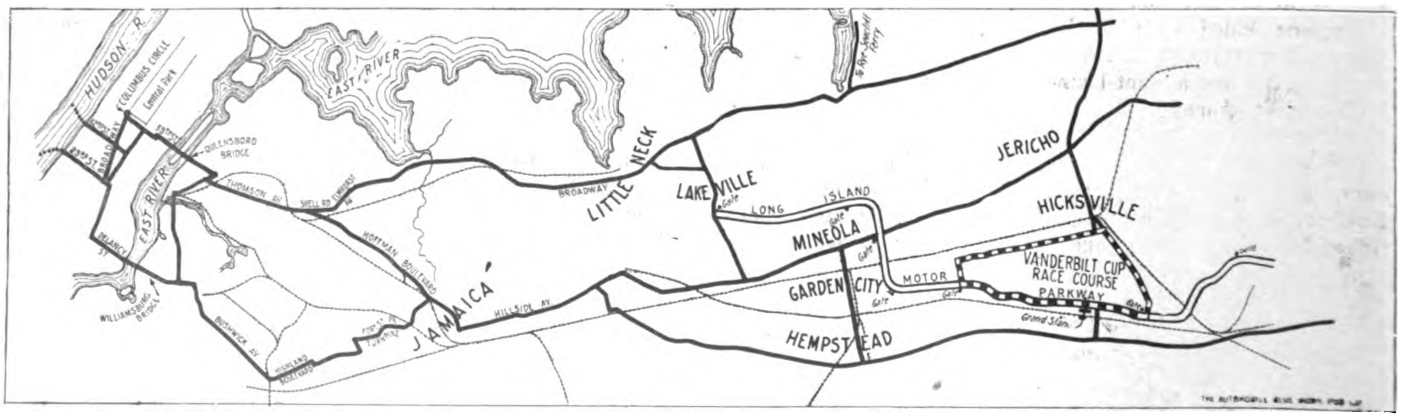
The Vanderbilt Cup race this year will be decided in large measure by the driving and such a galaxy of talent in that line has seldom been assembled in a single contest. There is not a single man who will handle the wheel in the cup race and the two sweepstakes who is not an artist. Most of them are veterans who have been in competition for years. Some of them are pioneers of the automobile racing profession and all have served their apprenticeship of hard, conscientious work to master the details of contest work. Robertson, Louis Chevrolet, Burman, Harroun, Matson, Montague, Roberts, Bill Endicott and Disbrow are in the front rank among the veterans, despite the fact that several of the above-named are smooth of brow and youthful, judged by the mere standard of years. Hearne, Grant, Fleming, Dingley, Aitken, Livingston, Dawson, Hanshue, Basle, and Knipper, are all masterly drivers whose names are associated with winners and whose knowledge of cars and speeds is intuitive. Bruce-Brown, Beardsley, and Wishard, have been amateurs so recently that one is almost obliged to class them together. In fact, Mr. Wishard's amateur standing is still debatable, despite the money prizes that await the winner of this contest. However, it would be difficult to pick out three more skillful drivers than this trio. Mitchell, Mulford, Arthur Chevrolet, Schiefler, Belcher, Juhasz, and Stillman, represent everything that goes to make up first-rate drivers. They all have strength, daring, and knowledge of track, road and the automobile, and if the winning of the race depends upon nerve and skill of the driver, any of them may win. De Hymel, the Aztec Indian; Jones, the 19-year-old youth, who will pilot the Amplex; Maisonville, the Corbin pilot in the Wheatley Hills; Sherwood of the Mercer; Oldfield, Abbott-Detroit, and his associates in the Massapequa, Mortimer Roberts and V. Padula, and Harry Endicott, and Limberg, are not so well known in the metropolitan racing field. De Hymel proved a world beater in Texas and the South. He is said to be as cool as Chevrolet and as easy as Lancia and to be as ready to take chances as Robertson or Harroun. Oldfield has driven in many races and is a strong, masterful youth with a keen knowledge of racing and contest work. The others have frequently driven in contests of various sorts and are competent men in the widest sense of the word.

Vanderbilt Cup cars and several others entered in the two minor sweepstake events were given moderately fast work Wednesday morning. There was nothing sensational about the time



MAP SHOWING THE BEST ROUTES BETWEEN GREATER NEW YORK AND VARIOUS POINTS ON THE COURSE
(Reproduced by permission of The Automobile Blue Book)

made except that the Pope-Hartford (Fleming) was sent around the course in 10:20 again. The principal other trials were as follows: National (Disbrow) 11:19; National (Aitken) 11:07; National (Livingston) 10:31; Marquette-Buick (Burman) 11:13; Benz (Heim) 11:14; Mercedes (Wishart) 11:21; Jackson (Scheifler) 12:03; Marquette-Buick (A. Chevrolet) 11:10; Marmon (Harroun) 13:15; Columbia (Stone) 11:07; Oldsmobile (Stillman) 11:56; Corbin (Matson) 17:11.

The Amplex (Jones) met with a mishap that may prevent the competition of the car. While going at a lively clip on the backstretch, the driver sought to avoid a motorcycle just at the close of practice and was obliged to make such a sudden turn that he dropped a torsion tube which resulted in some damage to the car. A hurry order has been sent to the factory for repair parts and the announcement has been made that a determined effort will be made to have the car on the starting line.

The official weighing-in will be completed Thursday night, after which the drawing for official race numbers will be held.

The officials of the race are as follows: Referee, William K. Vanderbilt, Jr.; judges, Henry Sanderson, Colgate Hoyt, Dave Hennen Morris, Robert Lee Morrell, and Samuel M. Butler; technical committee, A. L. McMurtry, Henry Souther and Alexander Churchward; A. A. A. representative, Frank G. Webb; assistant to the president, A. R. Pardington.

How to Reach the Grand Stand

Starting from Broadway, run east on Fifty-seventh street; turn left on Second avenue and right across Queensboro Bridge (toll 10 cents). At end of bridge turn right into Crescent street and at end of street turn sharp left into Nott avenue, crossing Jackson avenue. Curve slightly left over Thompson avenue railroad viaduct; then straight on into Hoffman Boulevard. At four-corners garage on left turn left into Hillside avenue direct through Jamaica. At iron sign post (four-corners) turn right on Queens road and left at end of road (15.0 miles). Take next diagonal right through Queens and Hempstead, straight road. Turn left (33.4 miles) to Grand Stand Long Island Motor Parkway (33.6 miles).

Coupe des Voiturettes

REMARKABLE TIME MADE OVER THE 282.4-MILE COURSE BY SMALL CARS, SOME OF WHICH DID 84 MILES AN HOUR ON THE STRAIGHTAWAY

BOULOGNE-SUR-MER, Sept. 17—An average speed of 55.7 miles an hour for a distance of 282.4 miles of hilly, winding road; one round of 23 1-2 miles officially covered at the rate of 58.7 miles an hour; an unofficial record of 66.4 miles an hour for another round; a speed of not less than 84 miles an hour on the straightaway—all this sounds like going fast. And it is not a revival of the Grand Prix race with 160-horsepower monsters that is under discussion, but merely the officially controlled speeds of the fastest cars in the Coupe des Voiturettes, where the bore of the little four-cylinder cars was not allowed to exceed 2 1-2 inches, or if you like to have it in accurate decimals, 2.559 inches.

If these little cars had been possible six years ago George Heath would certainly not have won the race for the Vanderbilt Cup. It is doubtful even if Louis Wagner would have held the trophy for the Darracq company, for 55.7 miles at hilly Boulogne is equal to more than 61.43 miles on level Long Island; it is equally doubtful if Sisz could have held his own on the straightaway Sarthe course against these terrible pigmies.

The race for the sixth annual Coupe des Voiturettes was one of the finest exhibitions of speed ever seen in France, and was particularly welcome after a monotonous series of aviation meetings. The seventeen entrants were reduced to fourteen almost at the last moment, the most serious loss being that of Giuppone, killed while practicing on a Lion-Peugeot only two days before the race; a Tribet smashed its clutch coming to the starting line, and a Saint-Lanne-Martinet, with a De Dion motor, quietly disappeared.

From the outset it was evident that the interest of the race lay between the Spanish Hispano-Suiza team of three four-cylinder cars, and the French Lion-Peugeot pair driven by Goux and Boillot. The Frenchmen were believed to be the faster, but the Spaniards had the advantage of being remarkably well prepared, their cars having been on the road for almost six months before the race. The others, although doing interesting work, were forgotten in the excitement of the Franco-Spanish duel.

A morning fog that rolled in from the sea held the start back from 7 to 8 o'clock. Then the cars were sent away at intervals of one minute, the course to be covered being one of 23 1-2 miles, comprising several 10 per cent. grades and numerous sharp turns, three of them being hairpins. Starting second, Zuccarelli finished first on the initial round in 25 minutes 35 seconds, easily beating last year's record of 29.28 over the same course. There was a surprise when the next car to roar by was Boillot's four-cylinder Lion-Peugeot which had started twelfth and passed the Hispano-Suiza, a Calthorpe, a D. S. P. L., a Corre La Licorne and a De Bazelaire. With a standing start Boillot had averaged 57 miles an hour. But there was still faster work, Goux coming round the course on his two-cylinder Lion-Peugeot in 24 minutes 33 seconds, or 17 seconds faster than his team mate.

All interest was now centered on the Lion-Peugeot and the Hispano-Suiza cars. Boillot led at the end of the second round, time 49 minutes 26 seconds, compared with 58.38, last year's record. At the end of the third round Goux was ahead, with Boillot 15 seconds behind him, and the whole Spanish team clinging on with grim determination. Goux made a desperate effort to shake the foreigners off, accomplishing his third round in 25 minutes 2 3-5 seconds, or an average of 58.7 miles an hour, this remaining the official record for the day. It was soon evident that Boillot could not get first place, for after two rounds his motor began to heat, necessitating a stoppage at the end of each round to take on water. But this did not make him spare his car; as he came down the gentle slope to the stands he drew up quickly and quietly without the least skidding of the wheels; in a fraction of a second the mechanic had the cap off the radiator, a cloud of steam shot out, more water was poured in, and almost before it was realized he was hurdling down the course to the graveyard turn, three-quarters of a mile away. Making allowance for the stoppage to take on water, he covered one of his rounds at the rate of 66.4 miles an hour, and his official time, including the stoppage, was faster than that realized by the winner Zuccarelli on any single round of the course.

From the third round onward the real struggle lay between Goux's two-cylinder Lion-Peugeot and Zuccarelli's four-cylinder Hispano-Suiza, with Chassaigne as a dangerous runner-up, and Boillot a violent sprinter unable to make up the time lost through his frequent but brief stops. At the end of six rounds, half distance, Goux had a lead of nearly two minutes on the Spaniard Zuccarelli, but it was not sufficient to assure him the victory, for on the next round he punctured twice, had to change with fixed rims and allowed Zuccarelli to get a lead of six minutes. On the eighth round the lead was pulled down to five minutes; on the ninth round it had been dropped to four minutes; on the tenth round it was still four minutes, and there remained two rounds to be covered, on each of which the Frenchman must gain two minutes in order to beat the Spaniard. Goux might have done it had he had ordinary luck with its tires, but on the eleventh round he punctured three times and occupied 38 minutes 5 seconds on the course which he had previously been covering in an average of 24 1-2 minutes. This lost him the race, for although Zuccarelli, who never once punctured, was held up by reason of a leak in his petrol tank, he got round the course in 29 minutes 3 seconds. Goux went for all he was worth on the last lap, but another puncture, the breakage of a shock absorber and the jumping of one of his driving chains from its sprocket held him down to 29 minutes 8 seconds for the round. Zuccarelli had won the race with a margin of exactly 17 minutes, had beaten last year's record established by Giuppone on a single-cylinder Lion-Peugeot by almost an hour, and had shown an average speed of 55.7 miles an hour.

With Boillot going lame, Chassaigne had not much difficulty in bringing his Hispano-Suiza home third with a margin of seven minutes. Collomb, who had run a very even course, brought his Corre La Licorne home fifth, but would certainly have been beaten by his teammate Levy had this car not been held back by frequent punctures, so frequent indeed that on one occasion it was necessary to wait an hour until fresh inner tubes were brought from the tire station. Pilliverde finished sixth on the Hispano-Suiza, thus securing the team prize for his firm. Levy on the Corre La Licorne came home too late to be timed.

One of the surprises of the meeting was the failure of the English team to get a single car home. Fred Burgess skidded on a turn, buckled a wheel, skidded again a few minutes later and broke his front axle. Garfield, also on a Calthorpe, lost the oil plug out of the base of his crankcase and was not long in seizing up. Frank Lewis, after covering half the distance, had the oil tank in the base of his crank chamber cracked by a flying stone, lost his lubricant and eventually seized. No. 1 Tribet car broke its crankshaft, an accident that was not unexpected, for it was known that a mistake had been made in the material supplied. Vallee on the four-cylinder D. S. P. L. overturned after covering one round; a companion car, after holding the road badly for nine rounds, withdrew from the fray. De Bazelaire, who had started with a stripped runabout, his racer having been wrecked a few days previously, averaged 40 miles an hour for half a dozen rounds, then made for home.

The feature of the cars entered for the race was the proportion of four-cylinder motors. In all the previous races single-cylinder cars have predominated, and have never been beaten. On this occasion there was 13 four-cylinder cars, one two-cylinder-motor, and three one lungers. Hispano-Suiza presented three four-cylinder models with the maximum bore of 2 1-2 inches and a stroke of 7 8-10 inches; this gives a ratio of stroke to bore of practically 3.07. The Spanish engineers had been satisfied to develop their motor on standard lines. Thus the four cylinders were a single casting, with valves on opposite sides, the diameter of the valves being considerable, but the valve chambers reduced to the smallest possible area. Timing gears were enclosed at the forward end of the motor, the high-tension Bosch magneto being driven off the right-hand side, and the water pump off the left-hand side. The head of the cylinders was dome shaped, the steel pistons had flat heads, were of unusual length and fitted with three compression rings. Tubular connecting-rods were employed. The crankshaft was carried in three ball-bearings. B. N. D. steel was employed for crankshafts, camshafts, connecting-rods, etc. The motor did its best work at 2,300 revolutions a minute, when it developed 45 horsepower, with an average lineal piston speed of 15 meters a second, or almost 3,000 feet a minute. Lubrication was of the forced feed type by a pump worked off the extremity of the intake camshaft, and the pressure on the gasoline was also maintained by an air pump worked off the motor. The drive was taken through a multiple disc clutch to a three-speed gear box, and by propeller shaft to the rear live axle, the number of teeth in the rear axle being 17 and 47. Rudge-Whitworth dismountable wire wheels were used, in conjunction with Michelin tires of 880 by 90. Total weight of each of the three cars, without oil or gasoline, was 1,455 pounds.

No attempt was made by the Hispano-Suiza engineers to gain speed by reducing head resistance. The cars carried large square honeycomb radiators, the bonnet stopped dead at the dash, and the rear of the two seats was a sloping platform on which a spare wheel was mounted.

The Lion-Peugeot people, who previously have run with two single-cylinder cars and one twin-cylinder V motor, this year produced entirely new models having the defect of not being thoroughly tuned up. Detail information regarding the motors is most jealously guarded. The cars were brought to Boulogne at night, while they were being weighed in a big screen was placed round them, and before the mechanics would dismount the cylinders the hall had to be cleared of all but officials. During the race Boillot had to lift his bonnet twice in the presence of the crowd in order to flood his carbureter, but he had it on again in a fraction of a second. When the race was over he placed a man in charge of the car with orders that the bonnet should not be raised, and to be doubly sure, ate his lunch in such a position that he could watch the machine all the time.

Goux's two-cylinder Lion-Peugeot motor was half exposed through the cut-away bonnet, and as this covering was abandoned during the race, a fair opportunity was given of examining the mechanical features. The two cylinders are cast separately and mounted in V-shape, with only a slight inclination from the vertical on an aluminum crankcase. Cylinder bore is the maximum of 80 millimeters (3.1 inches) and stroke is 11 inches. This gives a ratio of 3 1-2 to 1 stroke to bore. This motor, which has been designed by the firm's chief engineer, M. Michaud, differs considerably from the previous racing models produced for the firm by Boudreau-Vernet. There are three valves per cylinder, the intake being mounted vertically in the head of the cylinder, having a diameter of 2.4 inches and a flat seat, while the two exhausts are carried horizontally, one stem projecting toward the radiator, and the other toward the dashboard.

The second Lion-Peugeot, driven by Boillot, had four cylinders in V forming a single casting, their dimensions being 2 1-2 inches bore by 10.2 inches stroke; this is a ratio of 4 to 1, the highest employed for any motor yet produced in Europe. Theoretically this motor ought to have won the race, for it developed 45 horsepower on the bench, and was undoubtedly the fastest on the straightaway. Boillot lost a certain amount of time through the breakage of his gasoline feed pipe and the disarrangement of his foot brake. But the real cause of his defeat was overheating

TABULATED RESULT OF COUPE DES VOITURETTES RACE

Total distance 282.4 miles

Average 55.7 miles an hour.

		h.	m.	s.
1.	Zuccarelli, Hispano-Suiza	5	04	50
2.	Goux, Lion-Peugot	5	21	50
3.	Chassaigne, Hispano-Suiza	5	30	45
4.	Boillot, Lion-Peugeot	5	37	36
5.	Collomb, Corre La Licorne	6	28	16
6.	Pilliverde, Hispano-Suiza	6	37	[illegible]
7.	Levy, Corre La Licorne	not timed		

Fastest round, Goux, Lion-Peugeot, average 58.7 miles.

CHARACTERISTICS OF CARS

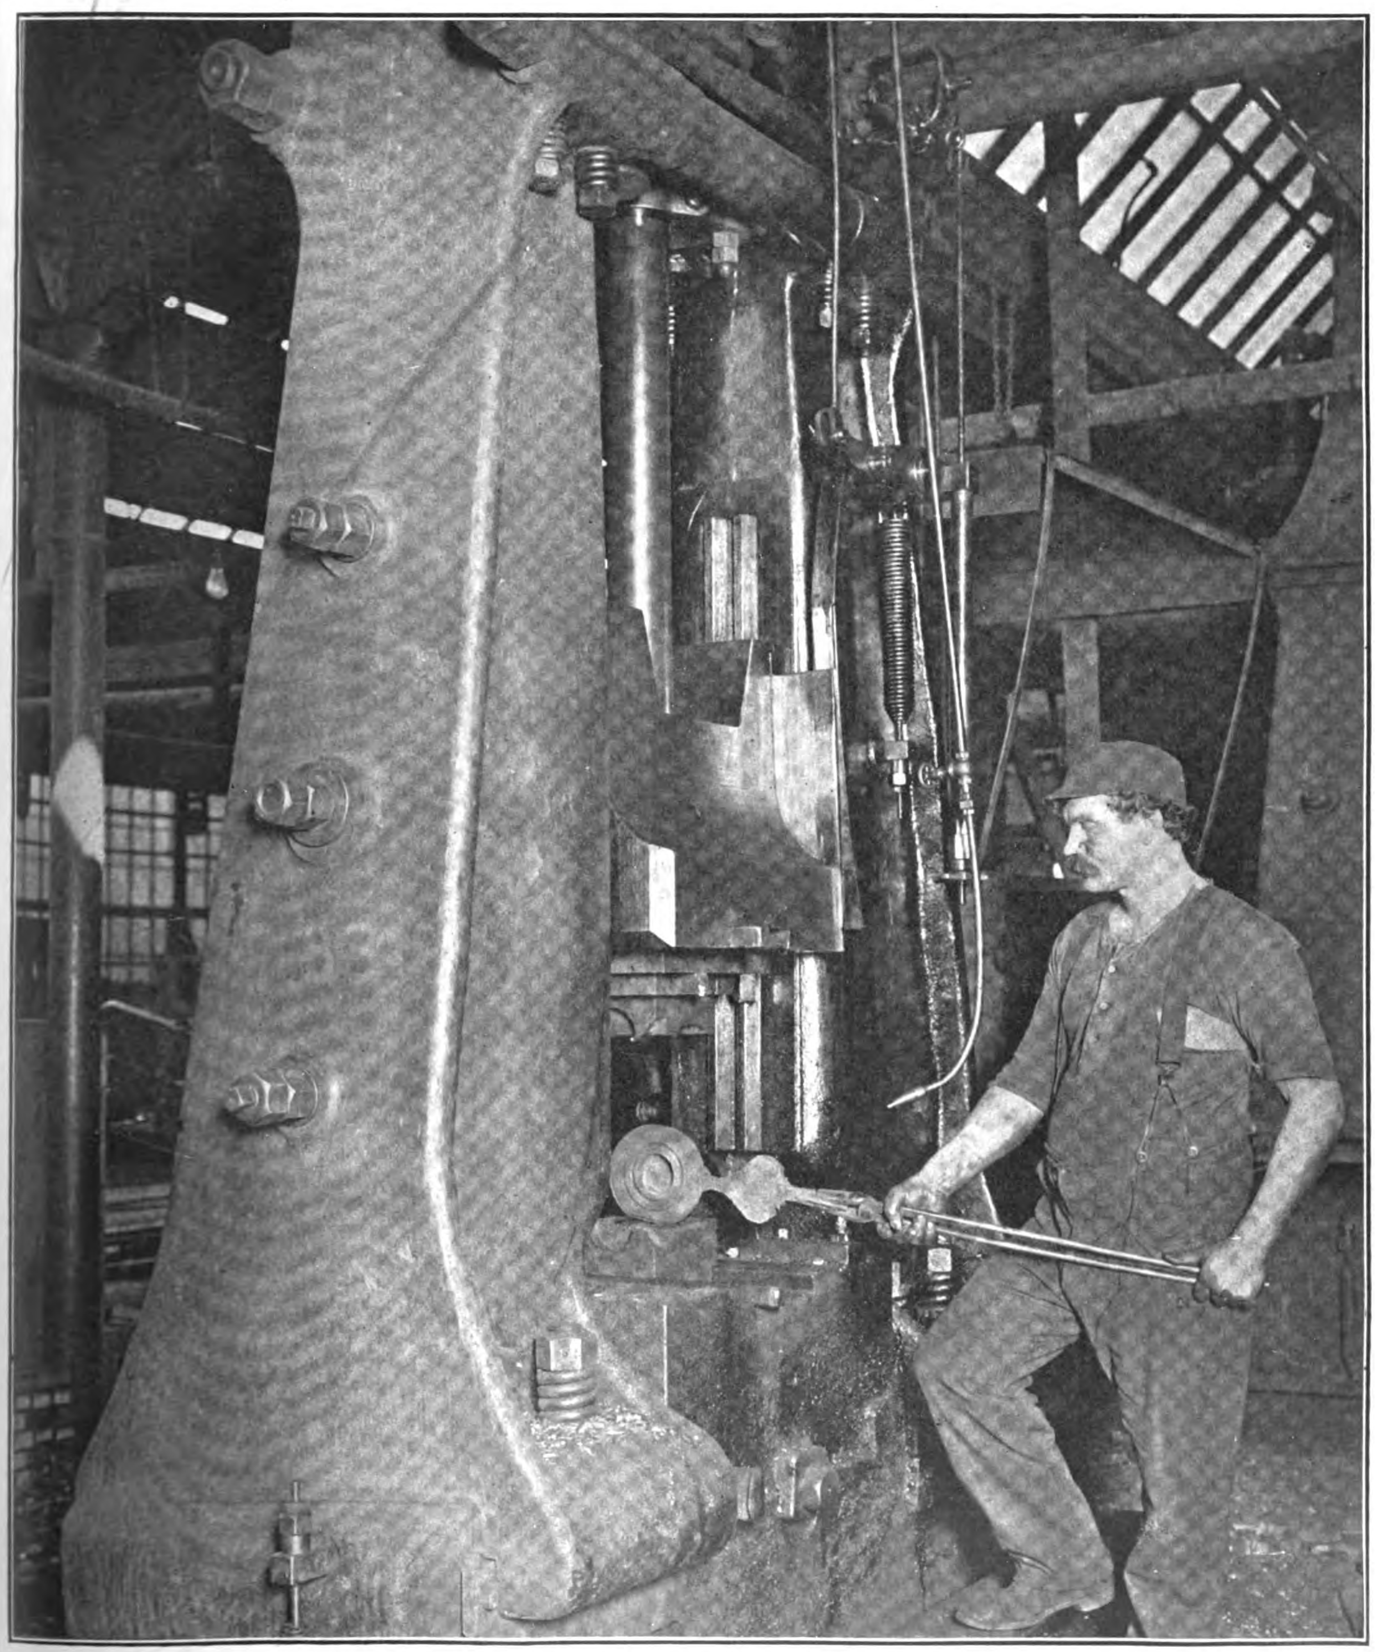
DEVOTED TO THE DISCUSSION OF ENGINEERING PHASES OF AUTOMOBILING, INCLUDING DESIGNING AND CONSTRUCTION FEATURES OF PRODUCTS, AND INFORMATION TO AUTOISTS



TO AVOID USING INFERIOR CASTINGS ENORMOUS HAMMERS ARE NECESSARY—SCENE AT RAMBLER PLANT

Auto as Locomotive

WILLIAM D. ENNIS, M.E., OF BROOKLYN POLYTECHNIC INSTITUTE, CONSIDERS THE MOTOR CAR FROM THE STANDPOINT OF THE LOCOMOTIVE DESIGNER

INTRODUCTORY.—The automobile is a train comprising a single self-propelled car running on the ground instead of on rails. It is the purpose of this paper to consider the motor car from the standpoint of the locomotive designer, rather than as a vehicle or a power engine, and to discuss the proportions of a typical example from this standpoint.

The specific automobile to which reference will be made is a 1907 Stoddard-Dayton, Model F, having a four-cylinder, four-cycle motor rated at 30 to 35 horsepower, with selective type transmission, three speeds forward and one reverse. The cylinders are 4 5-8 by 5-inch, tires nominally 34 by 4-inch, weight of empty car 3,025 pounds (54 per cent. on rear wheels), and gear ratios between engine and rear wheels of 11, 5 and 3 to 1 running forward and 14 to 1 reversed. This car was in 1909 subjected to a series of interesting power measurements by Messrs. C. Hidalgo and J. Harold McCreery on the testing floor of the Automobile Club of America. It has been the writer's privilege to examine the data obtained by these gentlemen.

Tractive Force

The ability of any locomotive to propel depends not upon its horsepower, but on the *tractive* or pulling force which it can exert. Work, or horsepower, is a formation both of the tractive force and the speed. A motor might have almost unlimited horsepower without sufficient tractive force to meet ordinary road conditions. To be satisfactory, it must exert the proper amounts both of tractive force and horsepower, the latter depending (after the former is fixed) solely on the speed. In Fig. 1 we have the simple case of one single-acting cylinder directly cranked to a wheel without intermediate gearing. The wheel makes the same number of revolutions per minute as the piston. Let

s = stroke of piston in inches,
P = average pressure continuously maintained on the piston in pounds per square inch,
d = diameter of piston in inches,
D = diameter of wheel in inches,
F = tractive or pulling force that could be exerted at the wheel rim, in pounds; the force that would be measured by a spring balance connected tangentially at the rim of the wheel.

Remembering that work is equal to force times distance through which the force is applied, we proceed:

$$\text{Area of piston} = \frac{\pi}{4} d^2 \text{ square inches,}$$

$$\text{Total average pressure on piston} = \frac{\pi}{4} d^2 P \text{ pounds,}$$

$$\text{Work at piston per revolution} = 2s \times \frac{\pi}{4} d^2 P = \frac{\pi}{2} d^2 sP \text{ inch-pounds.}$$

Let W be the work done at the wheel surface per revolution $= \pi DF$. Then, if there is no friction loss between piston and wheel,

$$W = \pi DF = \frac{\pi}{2} d^2 sP \text{ and } F = \frac{d^2 sP}{2D}.$$

Suppose the speeds of wheel and piston to be different, because of intermediate gearing: let N denote the revolutions per minute of the wheel, and n those of the piston. We then have,

$$\text{Work at piston per minute} = \frac{\pi}{2} d^2 nsP \text{ inch-pounds,}$$

$$\text{Work at wheel per minute} = NW = N\pi DF = \frac{\pi}{2} d^2 nsP \text{ and}$$

$$F = \frac{d^2 nsP}{2ND}.$$

In this connection, P denotes the average pressure continuously maintained. In a four-cycle engine there is perceptible pressure on the piston during one stroke only in the four; this when averaged over a single stroke is called the mean effective pressure; it is the average height of the indicator diagram, and its value is four times that of P. But if the engine has four cylinders we may obtain four times the value of F that is given by our formula, or P may be put equal to the mean effective pressure, the maximum of which for gasoline automobile engines will be not far from 100 pounds. For the car under consideration $d = 4\frac{5}{8}$, $s = 5$, D (diameter of wheels) $= 34$; letting $P = 100$ and taking $\frac{n}{N} = 11$ (first gear), we have

$$F = \frac{(4\frac{5}{8})^2 \times 11 \times 5 \times 100}{2 \times 34} = 1730 \text{ pounds.}$$

For second and third gears, respectively, we obtain

$$F_2 = \frac{(4\frac{5}{8})^2 \times 5 \times 5 \times 100}{2 \times 34} = 786 \text{ pounds,}$$

$$F_3 = \frac{(4\frac{5}{8})^2 \times 3 \times 5 \times 100}{2 \times 34} = 472 \text{ pounds.}$$

These are maximum theoretical values, assuming a perfect spark adjustment and no throttling, and are not realized in practice. Assuming them to be realized, however, what are the corresponding limits of speed? At 100 pounds mean effective pressure the horsepower at the pistons is

$$\frac{100 \times \pi \frac{d^2}{4} \times 2sn}{12 \times 33{,}000} = \frac{100 \times 3.1416 \times 4\frac{5}{8} \times 4\frac{5}{8} \times 2 \times 5 \times n}{4 \times 12 \times 33{,}000} = 0.0424\, n.$$

Suppose the maximum speed of the pistons at which full mean effective pressure is attainable to be 900 r.p.m. The horsepower for this value of n is

$$0.0424 \times 900 = 38.16.$$

The horsepower at the wheel rim is

$$\frac{34 \times \pi \times F \times N}{12 \times 33{,}000} = 0.00027\, FN.$$

The values of N for the three gears are:

$$\begin{aligned} N_1 &= 900 \div 11 = 81.8 \\ N_2 &= 900 \div 5 = 180. \\ N_3 &= 900 \div 3 = 300. \end{aligned}$$

Introducing the proper values of F, we have as the wheel rim horsepowers,

$$\left.\begin{aligned} HP_1 &= 0.00027 \times 1730 \times 81.8 \\ HP_2 &= 0.00027 \times 786 \times 180 \\ HP_3 &= 0.00027 \times 472 \times 300 \end{aligned}\right\} = 38.16.$$

If we put horsepower at wheel rim $= 38.16$, we have

$$38.16 = 0.00027\, FN,$$

$$\begin{aligned} N_1 &= 38.16 \div (0.00027 \times 1730) = 81.7 \\ N_2 &= 38.16 \div (0.00027 \times 786) = 179.7 \\ N_3 &= 38.16 \div (0.00027 \times 472) = 299.6 \end{aligned}$$

Under running conditions the circumference of the rear wheels of the car was 8.96 feet. The speed in miles per hour is then

$$M = \frac{8.96 \times N \times 60}{5280} = 0.1018\, N, \text{ which becomes}$$

$$\begin{aligned} M_1 &= 0.1018 \times 81.7 = 8.317 \\ M_2 &= 0.1018 \times 179.7 = 18.297 \\ M_3 &= 0.1018 \times 299.6 = 30.496 \end{aligned}$$

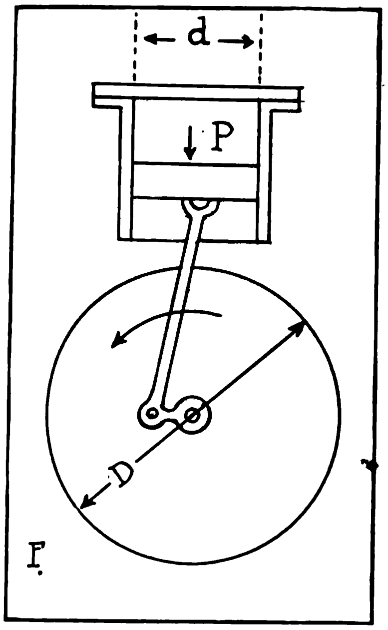


Fig. 1—Tractive power illustrated by a traction wheel directly connected to one single-acting cylinder

These are the maximum speeds that could be obtained theoretically with the respective gears and when developing the stated tractive powers.

Transmission Losses

In Fig. 2, suppose this car A to be set upon an immense hinged plan roadway B, the free end of the roadway being raised by the hyrdaulic jack C. The gears are in mesh and the car free to move. When the roadway is stationary or only slightly inclined, the car will stand still. When the free end has reached a certain elevation, the grade will become such that the car will start to run down the hill. If, immediately after the car starts, the elevation of the free end of the roadway is *slightly* decreased, the car may continue to move at a speed which will be found to vary with the amount of elevation.

The force which moves the car is the vertical component of its own weight, which may be readily compiled when we know that weight and the amount of elevation of the roadway. This force, then, may be used to measure the resistance to motion due to the internal friction of the automobile mechanism at rest or at whatever speed is desired. When once we thus know the amount of this internal friction we may reduce our values of F by these amounts so as to obtain the actual tractive force which, with the given mean effective pressure, could be exerted at the wheel rim or (more correctly) upon a spring balance restraining the car. The resistance due to friction is excessively high at starting, but this is ordinarily of little consequence.

In the experiments of Messrs. McCreery and Hidalgo the car was mounted on rollers and power was applied to the rear wheels from an electric motor. The amount of power consumed in driving the mechanism of the car at various speeds was estimated from the motor input. The results were as follows:

Gears	Speed in Miles per Hour	Horse Power Applied to Wheel Rim	Corresponding Traction Force, Lbs.
none	10.	1.18	44.31
none	18.2	2.4	49.51
none	30.8	4.05	49.38
none	40.4	5.38	50.01
none	48.8	6.81	52.40
first	4.	0.871	81.77
first	8.8	3.34	142.52
second	13.2	2.73	77.66
second	24.8	6.75	102.20
third	28.4	4.55	60.16
third	39.6	7.52	71.31

The first five results, of course, represent resistances due to the shaft and differential. The tractive forces corresponding to the measured horsepowers are thus derived:

$$HP = \text{force} \times \text{distance} = \frac{896\,FN}{33{,}000};$$

$$M = \text{miles per hour} = \frac{8.96\,N \times 60}{5280}, \quad N = \frac{5280\,M}{8.96 \times 60} = 9.82\ M;$$

$$HP = \frac{8.96\,F \times 9.82\,M}{33{,}000}, \quad F = \frac{33{,}000 \times HP}{8.96 \times 9.82\,M} = \frac{375.5\,HP}{M}$$

The deductions to be made from these figures are of considerable importance. The tractive force consumed in overcoming shaft and differential friction is practically constant showing a tendency to increase very slightly only as the speed increases. The horsepower lost in this part of the mechanism is consequently almost directly proportional to the speed. At a given speed, with gears meshed, the whole horsepower lost in the mechanism is apparently increased as the gear ratio is increased; so also, of course, does the loss of tractive force increase. Both losses increase rapidly as the speed increases, within the limits of the observations, the horsepower loss, of course, showing the more rapid increase. It must be remembered, however, that the measurements were made over trials of extremely brief duration.

Fig. 3 shows the results graphically. The economical advantage of using the high gear, from this standpoint, is obvious. Mechanical friction becomes a factor of no little importance in connection with high speeds.

Actual Pulling Power

The tests made on the car under discussion gave the following results:

Gear	Speed, Miles per Hour	Traction Force, Indicated, Lbs.	Horse Power Corresponding to Speed	Estimated Horse Power Exerted at Cylinder
3	41.4	180	27.3	19.7
3	42.8	200	30.7	22.7
3	49.2	160	29.0	21.
3	36.8	240	27.7	23.7
3	26.6	250	21.8	17.8
3	28.4	240	22.7	18.2
2	4.8	370	23.	19.
2	6.4	320	29.	22.
2	7.1	260	30.	19.5
1	2.8	740	...	....

The horsepower corresponding to the speed is, of course, MF ÷ 375.5, as already derived. The last column of the table gives the sum of this quantity and the friction horsepower, as estimated from Fig. 3. The following results may be derived from those just tabulated:

Gear	Speed, Miles per Hour	Horse Power at Cylinder	Friction Horse Power	Percentage of Horse Power Lost in Friction	Tractive Force Referred to Cylinder, Lbs.	Tractive Force to Ov'rc'me Friction, Lbs.
3	41.4	27.8	7.6	27.7	253	73
3	42.8	30.7	8.	26.1	325	75
3	49.2	29.0	8.	34.4	241.5	81.5
3	36.8	27.7	4.	14.4	308.5	68.5
3	26.6	21.8	4.	18.3	309.5	59.5
3	28.4	22.7	4.5	19.8	300.5	60.5
2	4.8	23.	4.	17.4	434.	64.
2	6.4	29.	7.	24.1	387.	67.
2	7.1	30.	10.5	35.	329.	69.

The power lost in overcoming friction is thus from 15 to 35 per cent. Of the total power developed, its proportion steadily increases with the speed and as steadily with the horsepower as could be expected with variable conditions in the cylinder. On third gear the tractive force falls off rapidly when the speed is something in excess of 40 miles per hour, or when 30 horsepower is taken out of the cylinder. A similar falling off in tractive force occurs on second gear at about 30 horsepower or a little less. As with the latter the piston speed at 30 horsepower is well below 1 000 feet per minute, it is difficult to explain the decrease in tractive force. With the third gear it is no doubt due to throttling and other vagaries of cylinder action to be expected with high piston speeds. The average tractive forces referred to the cylinder are, on third gear, 290 pounds, and

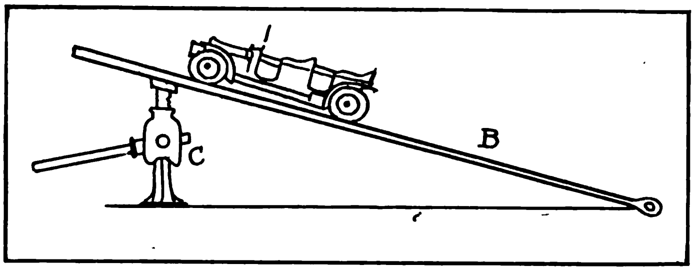

Fig. 2—Illustrating friction of machinery by the movement of an automobile on an inclined plane

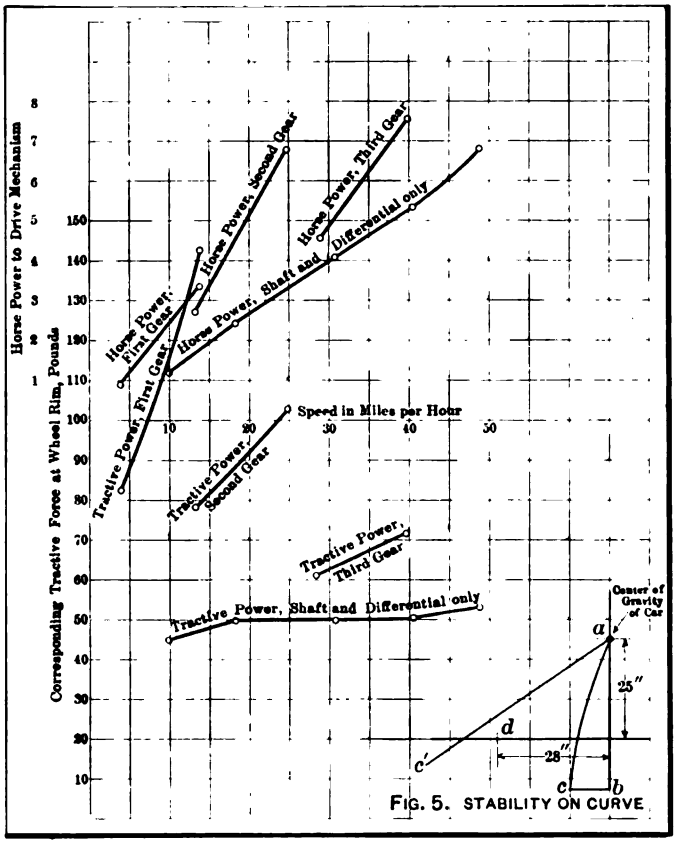

FIG. 5. STABILITY ON CURVE

on second gear 383 pounds, or 61 and 49 per cent, respectively, of those theoretically computed for 100 pounds mean effective pressure. A bad condition at the carbureter, spark or throttle might account for these apparently low tractive forces and mean effective pressures.

Propulsion Resistances—Wind

When a body bounded by a plane surface is subjected to a normal current of air, or moves normally in still air, a pressure is produced on the plane amounting in pounds per square foot of surface to

$$0.0025\ V^2;$$

in which V is the velocity in miles per hour. The total pressure over an area of A square feet is then

$$0.0025\ AV^2.$$

In a locomotive or automobile the value of A may be taken as the sum of the areas of the approximately normal surface, since a body partially protected by a wind shield may still be subjected to some resistance as the air eddies around the latter. For the car in question we may then perhaps take A at 28 square feet, whence the resistance is

$$0.0025 \times 28 \times V^2 = 0.07\ V^2 \text{ pound.}$$

No provision is made for measuring this in testing cars by the method referred to; for, although a large fan blows air against the front of the radiator for cooling, the car does not move against this current of air nor does the presence of the latter influence the amount of power exerted by the motor. The tractive forces necessary to overcome wind resistance alone are then about as follows:

Speed in miles per hour	Resistance due to velocity in still air, pounds
10	7
20	28
30	63
40	112
50	175
60	252
70	343
80	448
100	700

If there is a head wind, the velocity of the wind must be added to that of the car to obtain the equivalent speed. Thus, a car running at 40 miles per hour against a head wind of 20 miles per hour experiences a wind resistance of 252 pounds. It appears that, as in railroad locomotives, wind resistance is of little importance at low speeds (say, below 20 miles per hour), but of serious effect at high speeds. Based on the figures given, a racing car at 70 miles per hour would experience an extra resistance of 3.06 pounds from an extra normal surface 6 inches square—say, a man's head—and this would sacrifice more than half a horsepower.

Grade Resistance

The principle of grade resistance is illustrated in Fig. 4. A is a body free to move only on the inclined plane. Its weight acts downward along the line W. This downward force may be resolved into the components N, normal to the plane, and R in line with it. The component R retards the car. Since $R : W :: Q : L$, $R = \frac{Q}{L} W$, or the resistance due to a grade is equal, in pounds, to the weight of the car multiplied by the proportion of rise in the grade: Roughly, 20 pounds per ton of car weight per 1 per cent of grade. For the car in question, which, when loaded, weighs, say, 3,800 pounds, the resistance due to grade only, on a 1 per cent. grade, is 38 pounds; on a 4 per cent. grade 152 pounds, and so on. A car must have tractive force sufficient to overcome the resistance of the steepest grade it is likely to encounter, otherwise no amount of horsepower will make it mount the hill. This is to be accomplished by using large cylinders, six cylinders rather than four, small wheels, or a high gear ratio, or by a combination of these methods; and, after all, the operating conditions at the motor will affect the tractive force more than any other factor.

Speed on Grades—Curves

The highest tractive force is developed on the first gear, and this gear must, therefore, be used on the worst grades. This means a comparatively slow speed, since at 10 or 12 miles per hour the piston speed will have reached 1,000 feet per minute. It is desirable to use second or even third gear unless the grade is such as to stall the motor, and greater economy, of course follows the use of the higher gear. When a car is stalled on a grade, even because of a bad throttle or spark position, it may be necessary to drop to a lower gear (higher ratio) in order to start again, because the friction of a motionless machine exceeds that of one in motion (see explanation of Fig. 2).

In locomotive practice attention must be given the resistance due to pressure of wheel flanges against rail heads resulting from grades or side winds. Side winds have been known to overthrow trains on account of the large surface exposed. The side surface of a motor car rarely exceeds 35 square feet, and a wind velocity of 60 miles per hour would then give a pressure of only $0.0025 \times 35 \times 3600 = 315$ pounds. This produces no perceptible resistance to propulsion. In rounding a curve the centrifugal force, in pounds, is

$$\frac{Wv^2}{32.2\, r},$$

in which W is the weight of the car, v its velocity in feet per second, and r the radius of the curve which it is rounding, in feet. For $W = 3800$, $v = 60$, $r = 600$, this becomes

$$\frac{3800 \times 3600}{32.2 \times 600} = 707 \text{ pounds.}$$

For $v = 60$, the speed in miles per hour is $\frac{60 \times 3600}{5280} = 41.2.$ At this speed, when rounding a curve of 600 feet radius, the car would develop a centrifugal force tending to push it toward the outside of the curve amounting to 707 pounds. Suppose this to be coupled with a side wind pressure in the same direction of 315 pounds, making a total side pressure of 1,022 pounds. In Fig. 5 we have the condition of stability on a road without superelevation, the center of gravity of the car being assumed to be 25 inches above the ground and the tread being 56 inches. The vertical line a b represents the weight of the car (to any scale), c d represents the side force of 1,022 pounds to the same scale, and the straight line a c represents their resultant. If a c fell beyond d, like a c the car would overturn. In this case it is amply stable. The centrifugal force would have to be about 4,000 pounds to overturn it. This would involve a curve of 100 feet radius at about 41 miles per hour, or a curve of 200 feet radius at 58 miles per hour. The following would be the limiting speeds on various curves with no side wind pressure:

Radius of curve, feet	Limit of speed, miles per hour
100	41.
150	50.2
200	58.
250	64.9
300	71.
400	82.
500	91.8

The possibility of reaching unsafe speeds under road racing conditions is widest. A low center of gravity or a wide tread leads to stability.

Acceleration

It is seldom that any close calculation of acceleration resistances need be made. The basic formulæ are, however, as follows:

$$F_0 = 95.6\frac{V_2 - V_1}{t} + \frac{0.125}{T} \cdot \frac{V_2^3 - V_1^3}{V_2 - V_1},$$

$$F_1 = \frac{V_2^3 - V_1^3}{V_2 - V_1} \cdot \left(\frac{23.33}{s} + \frac{0.125}{T}\right),$$

in which F_0 is the net constant amount of tractive force required to accelerate and overcome wind resistance in bringing a car weighing T tons from a speed V_1 to V_2 (miles per hour) in t seconds, and F_1 is the force similarly necessary to produce the same increase of velocity in the distance s feet. Additional tractive force must be provided to overcome grade and frictional resistances.

Total Tractive Power and Adhesion

In designing an automobile it is necessary to give the motor the required tractive force to meet any probable combination of resistances and to then make the horsepower such as the speed requires. For example, with a gear arrangement and weight of car such as have been described, suppose (*a*) a speed of 60 miles per hour to be required on a straight, level road, (*b*) a speed of 30 miles per hour on second gear to be demanded on a 6 per cent. grade, and let it be necessary (*c*) that the car should attain a speed of 40 miles per hour, starting from rest, in 19.65 seconds when on a level road.

For condition (*a*) the frictional resistance on third gear appears likely, from Fig. 3, to be about 90 pounds. The air resistance is

$$0.07 \times 60 \times 60 = 252 \text{ pounds,}$$

making a total resistance of $252 + 90 = 342$ pounds.

For condition (*b*) the grade resistance is

$$6 \times 3800 \div 100 = 228 \text{ pounds,}$$

the air resistance is $0.07 \times 30 \times 30 = 63$ pounds, and the frictional resistance, from Fig. 3, is 115 pounds, making a total resistance of

$$228 + 63 + 115 = 406 \text{ pounds.}$$

To meet condition (*c*) we must overcome friction corresponding to mean speed of not far from 20 miles per hour—say 55 pounds on third gear or 92 pounds on second (Fig. 3). The combined wind and acceleration resistances are, from the formula given,

$$F_0 = 95.6\left(\frac{40}{19.65}\right) + \frac{0.125}{1.9} \cdot \frac{40^3}{40} = 300 \text{ pounds.}$$

The total resistance for this condition is then, with third gear, 355 pounds, and with the second gear, 302 pounds. Considering all three conditions, the machine must be capable of exerting a tractive force of 355 pounds on third gear and of 406 pounds on second gear. Taking the formula given

$$F = \frac{d^2nsP}{2ND},$$

and making $\frac{n}{N} = 5$ or 3, as the case may be, $D = 34$, $P = 100$, we have, for third gear,

$$355 = \frac{3 \times 100\, d^2s}{68} \text{ whence } d^2s = 80.3,$$

and for second gear

$$406 = \frac{5 \times 100\, d^2s}{68} \text{ whence } d^2s = 55.3.$$

We must adopt the higher value: and even this is based on $P = 100$, whereas the trials considered warrant values of P of only 61 for third gear and 49 for second. If we introduce these, the governing combination is $d^2s = 132$.

Now let us consider horsepower, using the formula $\frac{MF}{375.5}$.

For condition (*a*),

$$HP = \frac{60 \times 342}{375.5} = 54.3. \text{ For condition } (b),$$

$$HP = \frac{406 \times 30}{375.5} = 32.5, \text{ and for condition } (c),$$

$HP = \frac{355 \times 40}{375.5} = 37.6$ on third gear and $\frac{392 \times 40}{375.5} = 41.5$ on second—both maximum values after the attainment of the stated speed. The conditions are not harmonious as to power; but with the extreme flexibility due to gears it is quite possible for the designer to meet any assigned grade, speed and acceleration conditions with a reasonably uniform size of cylinder as computed for each. If we take the empirical formula for horsepower, for a four-cylinder machine,

$$\frac{4d^2}{2.5}$$

our maximum condition requires that

$$d^2 = 2.5 \times 54.3 \div 4 = 33.9 \text{ and } d = 5.83 \text{ inches,}$$

whence

$$s = 132 \div 33.9 = 3.9 \text{ inches.}$$

This would give a badly proportioned motor, and the empirical formula used should be one which includes both d and s, leading to an equation in the form

$$ds = a, \text{ a constant,}$$

$$s = \frac{a}{d},$$

$$da = 132,$$

$$\left\{\begin{array}{l} d = \dfrac{132}{a}, \\ s = \dfrac{a^2}{132}, \end{array}\right\}$$

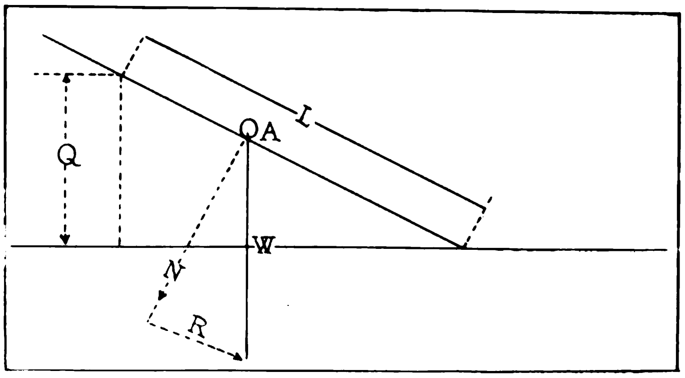

Fig. 4—Illustration of the principle of grade resistance

Novel Air Compressor

DESCRIPTION OF A NEW MECHANICAL MOVEMENT SHOWN AT THE BRITISH ENGINEERING EXHIBITION WHICH CAN BE APPLIED TO THE MOTORING FIELD

ONE of the most interesting exhibits at the Engineering Exhibition held at Olympia, says the *Commercial Motor,* London, was the air compressor shown by Lamplough & Son, Ltd. Its designer appears to have evolved an entirely new mechanical movement—one which has many practical applications in the field of commercial motoring. The same principle of construction is not limited to air compressors and exhausters, but it may be applied to pumps for oil or water, and, perhaps, we are not overestimating its probabilities if we predict that, in a modified form, it may ultimately be employed as a rotary internal-combustion engine of unique characteristics.

The design has been developed from well-known devices in which segmental pistons are employed to divide an eccentric chamber into a number of pockets whose volumes are constantly varied as the segmental pistons are driven round a circular path within the eccentric chamber. A working drawing, which shows the general arrangement of Mr. Lamplough's beautifully conceived device, is reproduced herewith (Fig. 2). This illustration shows that all the parts may be machined cheaply on a lathe; no piece, in fact, presents the slightest difficulty either in the making or the fitting stages of its production.

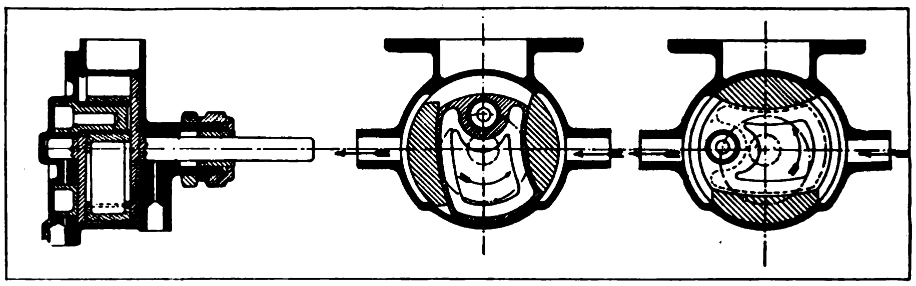

Fig. 1—Sectional views of a Lamplough double-acting positive pump

The driving shaft (A) is mounted on ball bearings in a casing which consists of two end chambers (B), which are concentric with the shaft, and an eccentrically-disposed barrel (C). Two driving discs (D) are keyed on to the shaft, and each of these has four equally-spaced counter-bored recesses in which oscillating cylinders (E) are fitted. Each of the oscillating cylinders has a crankpin (F) which engages in a journal in one end of one of the segmental pistons (G). All the oscillating cylinders, their crankpins and the segmental pistons are hollow, and, in the drawing, are shown in solid black sections. The segmental pistons may be cooled by the circulation of water or oil through them; midway of their length, they are provided with grooves (H) which permit of the passage of air or gas to or from the inlet or outlet ports and the pockets (J1, J2, J3, and J4) between adjacent pairs of pistons. The outer circumference of each segmental piston is kept up against the bored barrel (C) by means of a floating sleeve (K), while scoring of the barrel by the pistons, by reason of the centrifugal force, is prevented by the introduction of two external floating rings (L). The adjacent surfaces of the pistons and the bore of the barrel, therefore, are not in actual contact with each other, but are separated by a film of oil (the lubricating medium) which is relied upon to form a seal for the prevention or the minimization of leakage from one pocket to another.

The operation of the device is as follows: When the shaft is driven round in the direction of the arrow, it carries with it the two discs (D) and the oscillating cylinders (E); the power is thence transmitted, through the crankpins (F), to the segmental pistons (G), and these then travel round in a circle prescribed by the bore of the barrel and the outer circumference of the floating sleeve. As the path of the pistons is prescribed, so also is the path of the crankpins, but, as the latter path does not coincide with that of the centers of the cylinders (E), the cylinders are compelled to oscillate in their sockets; the effect of this oscillation is alternately to accelerate and retard the segmental pistons during their circular progress within the barrel, and the capacities of the pockets is thereby constantly varied. When used as an air pump or compressor, this alteration of the capacities of the pockets is employed, first, to draw in air through the inlet port; second, to compress the indrawn air and, finally, to discharge it through the outlet port. Reference to the transverse section will show that: the pocket J4 is open for the admission of air; the pocket J3 contains an imprisoned charge of air at the same pressure as that at which it was admitted; the pocket J2 contains a fully-compressed charge about to be delivered through the outlet port; and the pocket J1, having squeezed out one charge, is about to open again for the admission of air for a fresh cycle of operations. In this manner, there are four deliveries of compressed air per complete revolution.

Two photographs of one of the demonstration models which are exhibited are reproduced herewith (Fig. 3); the first shows the pocket J1 just opening for the admission of air—the pocket J4 has opened earlier for the escape of its charge; the other view shows that the pocket J2 has just closed, and that the charge in the pocket J3 has been compressed into about one-half of its original volume. It should be noted that this pump's action is positive, and that there are no valves or reciprocating parts. It is understood that one of these pumps, when used as an exhauster, reduced the pressure inside a chamber to within one inch of a complete vacuum.

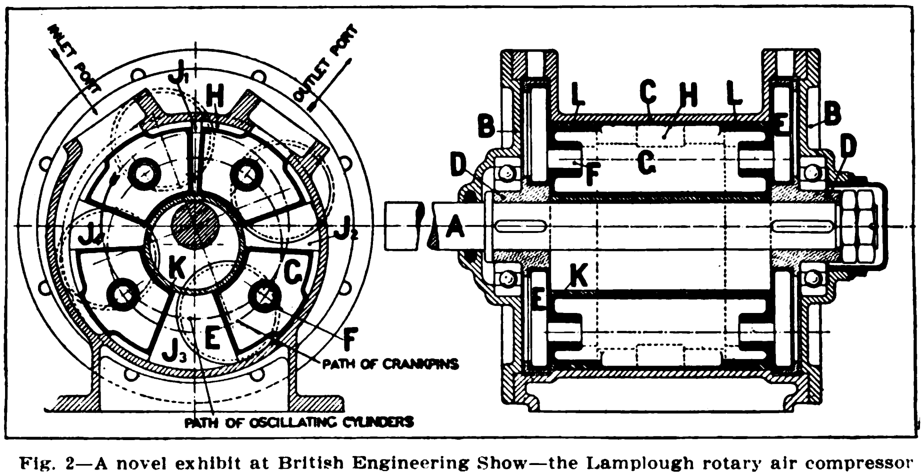

Fig. 2—A novel exhibit at British Engineering Show—the Lamplough rotary air compressor

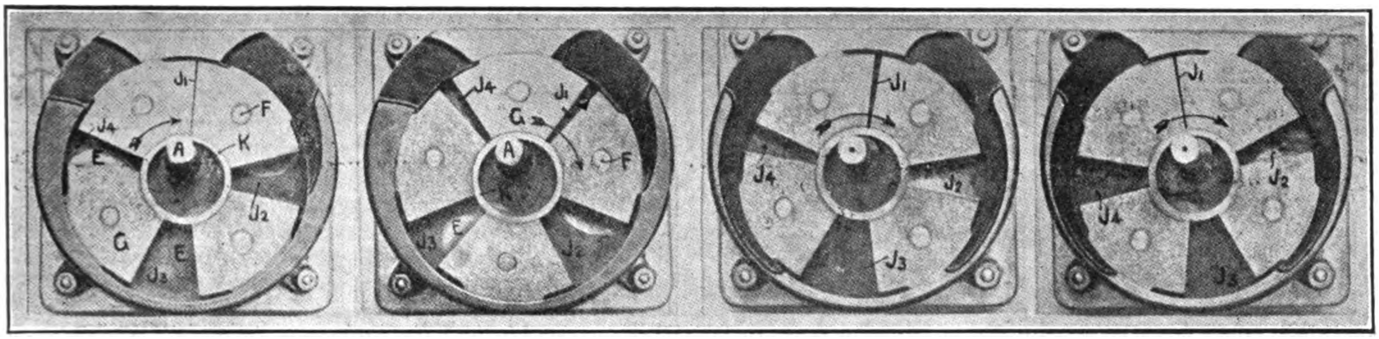

Fig. 3—First and second views show various stages in the cycle of a Lamplough air compressor. The other two views are of a blower constructed on the same principle

A model of an alternative form of blower, in which the charge is delivered against pressure but is not compressed internally, was also mounted on Lamplough's stand, and two photographs of the latter model are also reproduced herewith. A reference to those views—the third and fourth at the top of this page—will show that the inlet and outlet ports are both longer than those in the pump already described.

The latter form of construction has been employed for the purpose of forcing a charge into the cylinders on a two-cycle petrol engine, and such an engine was exhibited. Its two pistons operate on the same crank, and the charge is admitted through a port which is uncovered by the piston in No. 1 cylinder immediately after the exhaust port is uncovered by No. 2 piston. There are no valves, and the inrushing partly-compressed charge is relied upon to scavenge the previously-exploded charge. Speeds up to 3,000 r.p.m. have been obtained.

A large range of Lamplough patent double-acting positive rotary pumps for oil or water was also exhibited and sectional views of this type of pump are given on the opposite page. This pump comprises but three working parts: a curved plunger path which is cast integral with the driving spindle; a curved plunger; and a crankpin which engages in a bushed hole in the plunger and a slot in the plunger guide. The crankpin travels round the driving spindle at the same speed as the latter, but is eccentric to it; it, therefore, imparts a reciprocating motion to the plunger. Three views are given (Fig. 1): the first shows the plunger in the middle position of its stroke; in the second one, the plunger is shown just about to start sucking in water at the top and delivering from the bottom of the plunger; the remaining view is a longitudinal section through the complete pump.

One of these pumps was exhibited at the stand connected to a small cylinder into which it delivered oil against a pressure of 300 pounds per square inch.

Airships and the Navy

SOME OBSERVATIONS BY DR. ROBERT GRIMSHAW ON THE PART THAT DIRIGIBLE AIR CRAFT WILL PLAY IN FUTURE CONFLICTS ON THE OCEAN

WHEN one says "airships," the accompanying or suggested thought is immediately "military reconnoitering and attack." This is notwithstanding the fact that the airship in its various forms of motor-aeroplane, dirigible and captive balloon, etc., is destined to play eventually an important rôle in suppressing all purely military operations by making it almost impossible to fortify a country in advance in such manner that the plans for defence cannot be discovered by photography from above on the part of investigators posing as peaceful aerial commercial voyagers or tourists—as in times of peace the air must of course be considered free to all.

The attention of the public is, however, now attracted to the fact that the dirigible airship, the motor-driven balloon and other aerial vessels have as much interest and value for the navy as for the army; although the former has evinced a seeming indifference to all that appertains to the navigation of the upper regions.

In fact, however, the admiral has just as much need of information concerning the enemy's position as has the general. The Russo-Japanese war showed the importance of obtaining and communicating such information. A balloon or other airship can pass unhindered over an obstacle, as a high mountain, photograph or sketch the position, and observe each movement of every ship of an inimical fleet, and communicate this in great detail by wireless telegraphy or telephone—even by visual signal or by the ordinary electric methods—to an attacking squadron.

But the work of aerial craft in aiding the navy is not confined to reconnaissance; they can also be used to inflict injury upon land or marine forces or defences. So in considering this topic we can divide the service into harbor and high-sea work, and each of these classes into reconnaissance and attack; under the latter being understood active defence, also.

The craft available for aerial navigation are either heavier or lighter than air, and either class may be self-propelled, towed, or merely steered; but the merely steerable non-propelled aeroplane is as yet comparatively undeveloped. Towing may be either by automobile or by a water craft.

As far as the navy is concerned, the use of aerial craft will in the first place be that of observing fortified or other harbors. These represent the entrenched or otherwise strengthened positions of the army. The aerial observer records and reports the position and character of defending forts, the number and class of war vessels stationed in the harbor, the operations of torpedo-laying forces, the path of maneuvering vessels—including sub merged submarines—and the torpedoless and mineless channels open to the attacking squadron. Where the water is clear, the position of ground mines can often be observed from an airship; and naturally that of floating mines may be mapped without difficulty, even without the aid of photography.

The general advantages of reconnaissances made from any one of the principal classes of airships are that the view is unobstructed by laterally intervening dust or smoke, to say nothing of woods, buildings and hills; and that the field of view embraces a complete circle. This is seldom or never the case where the observer is stationed upon a hill or mountain, however high. Naturally, too, the greater elevation attained the greater the field of sight. Further, there is the advantage of the overhead observer's being able not only to choose, but also to attain, the desired place of observation, and to return uninjured to the security of his own lines.

Each of the above-mentioned methods of reaching the desired station has its advantages and its partially corresponding disadvantages. In all, however, the advantages are much greater than, as a rule, the public and even the military and naval authorities have been inclined to state or even believe. This is largely because they have failed to put themselves in proper communication with those statisticians who accurately observe, record and tabulate meteorological conditions.

In reconnaissance the cellular kite towed by a motor boat is of course comparatively useless; but its value can be readily seen when one contemplates the other branches of reconnaissance, attack and defence.

The ordinary captive balloon has long ago been repeatedly tried for reconnaissance, but has as often proved unsatisfactory, on account of being so largely dependent upon the direction of the wind, which may either carry it so far over the enemy's lines as to endanger its occupants' safety, or refuse entirely to drive it in the desired direction. In addition, the height to which such mediums of observation can rise is limited.

The motor balloon or motor aeroplane would find its work in the neighborhood of the coast, in or before fortified ports. Its duties in war-time would be like those of reconnoitering parties at present. The defending party, which is supposed to be blockaded in its own port, would use it to observe, and transmit information concerning, the position, number, character and movements of the blockading fleet; further, to note and report upon the results of its own fire, with the object of correcting errors and improving or altering the aim, in case the target was moved to avoid the missiles.

On the other hand, the attacking or blockading fleet would use such overhead craft to report upon the fortifications, so long as their position had not been made known by previous aerial scouts, either during or before the war in question; or to state whether they were fully manned or gunned, and well served. If the water were clear, the actual location of ground mines could be compared with their supposed position, and any movements of submarines could be noted, with details as to ease and completeness of submergence, speed on and under water, degree of controllability, etc.

It must be understood at the outset that the towed balloon or aeroplane, whether the towing medium be an automobile or a motorboat of any kind, can be used, for observation at least, in many places where the configuration of land or water would not at first seem to render such operations possible. For while the angle at which a towed waterboat stands, and the course which it takes, as regards the towing medium, are comparatively limited, yet where there is a peninsula partially surrounding a harbor, an automobile may take charge of a captive balloon or aeroplane, and after taking such course as the configuration of the land permits, brings its "tow" to a position from which the wind will sweep it directly over the enemy's forces; and what is of equal importance, bring it back again to a convenient height from the ground by winding in, and then return with it to headquarters. Similarly, a motor boat may take a balloon or plane to a point from which it may ascend to the desired height, and then get a better view than could have been obtained from the starting-point.

The self-propelled aeroplane—and in using this term the writer does not confine himself to monoplanes, but includes the cellular kite type—would with proper motive power and good management be able to get good snapshots of the fleet attacking a harbor.

Reconnaissance by self-propelled balloon would have vast advantages over that by self-propelled planes; as the former with a very small expenditure of motive power could stay for hours or even days in the air, above the enemy's forces, moving only sufficiently to get out of danger when shots from below showed that the line of aim was getting dangerously near the right one; or by dropping ballast from time to time, remaining at a height just sufficient to keep out of shot.

Considered as attacking mediums, as for instance for dropping explosives upon the deck of an opposing fleet, or into a convenient place—say the powder magazine, in case the position of this latter should be known as the result of previous or other balloon reconnaissance or through land spies—the motor balloon or the aeroplane, whether self-propelled or towed by either automobile or boat, has at present great advantages, as up to date no modern war vessel is equipped with howitzers or other cannon capable of firing at a very high angle. The only manner of destroying a reconnoitering or attacking balloon or aeroplane would be to reach it with a sure shot from some point far enough from the threatened point to enable the attainment of the requisite elevation for the gun. This, however, would usually be at such a distance that the aim would be very much impaired.

In case of a blockade the motor airship, or with favorable wind even a captive balloon or cellular kite, would be of immense service; as the former would have facilities for convenient and repeated filling, and either would be capable of returning to its station on land—the former by its own motive power, the latter by hauling in the tow-line with a windlass, or even with an automobile.

Hauling in would also be of service in case a dirigible should adopt the precaution of taking with it a fine steel tow-line capable of being rapidly paid out and hauled in; so that if the motor of an airship were crippled there would still be a means of return to a place of safety.

The captive kite rises with increasing ease and to a greater height, with increased velocity of the propelling wind; but has the disadvantage that, should the current not be in the right direction, or should the towing vessel not be able to draw it in the general direction of the scene of observation, it cannot be used at all, as tacking—so long unknown to ocean navigators, at first thoroughly at the mercy of the winds and currents or tides—has not been successfully applied with either non-dirigble or self-propelled airships. But the towed cellular kite and its congeners are useful up to the point where the wind's velocity is over 20 meters per second, or say 45 miles an hour.* Meteorologists have, however, shown that this rate—that of a good railway train—is exceeded only about ten days in every hundred—at least in Germany.

The motor-propelled airship is independent of the wind up to that point where the latter has a velocity equal to that with which the aerial craft can propel itself where there is no wind. The airship "Zeppelin IV" traveled 15 meters a second, or say 35 miles per hour; and that fixes the point up to which it is serviceable; but there is no doubt that with improvements in motors, transmission, propellers and form of hull this speed will be greatly exceeded in the very near future. And the same statistics which aeronauts should have consulted before constructing their vessels and which the military and naval authorities should keep in mind when estimating the value of aerial craft, and expressing their opinion thereof, show that in only 12 days in a hundred is this speed of 35 miles an hour exceeded.

A motor airship designed for a long range of action, whether as accompaniment for the regular fleet, or for action on its own initiative, must be especially constructed so that it shall be entirely independent of the latter as regards supplies of food, motive fluid and material of war; although these could be carried on the airship merely as reserves for independent action, and all supplies for daily consumption and use received from the fleet convoys (or even the war vessels), so long as the airship remained in touch therewith.

The airship which takes the place of a steam pinnace must have a place therefor arranged on the deck of some war vessel, or at least of some convoy. Here comes the problem which is most difficult of safe and convenient solution—as there is already too little room on board the modern war vessel. The motive engineering department of every navy complains that when a vessel is designed the positions of armament and armor, and of coal bunkers considered as defensive armor, are deter-

---

* One meter per second is very nearly exactly 2.25 miles an hour.

mined beforehand by the designers; and that any space which may happen to be left over, no matter what may be its size, form or position, is graciously given up for boilers, engines and accessories. Under this state of affairs the "aerial" department would naturally be the last to be considered in the design of a new vessel; and in the case of a ship already afloat, the chance of finding proper quarters thereon for balloons and their appurtenances would be rather slim.

An advantage of airships for coast defence would be that there would always be room in or near the harbor for a large number thereof, which could be used either together for a sudden or other combined attack, or consecutively for long-continued harassing of the attacking fleet. The further advantage of numbers in this particular would be, that no one such aerial vessel would have to carry a very great weight of explosive material, or of gasoline or other propelling liquid.

There is at present no nation for which the question of aerial vessels for defence is of more importance than the United Kingdom—as once the war balloon and its congeners attain any degree of practical utility in attack, Great Britain and Ireland cease to be islands! "The wooden walls of Old England" have long ago been replaced by steel; but as against an energetic, well-commanded Continental power equipped with a good fleet of properly-manned aerial war vessels, a balloonless England would find its boasted floating and other defences, in the words of Prospero, "melted into air, into thin air."

When it comes to the matter of aerial war craft on the high seas, the problem to be solved assumes a very different aspect from that for coast attack or defence. Here the use of a self-propelled balloon or motor aeroplane is out of the question, as either of these requires to be landed from time to time for repairing, avoiding dangerous air currents, etc.; and the former for re-filling. There must be special arrangements for generating gas, and for filling captive or dirigible balloons with hydrogen, or an equivalent or substitute generated on board, as often and in such quantities as might be required; or else highly compressed gas must be stored in strong steel cylinders to be used when needed; or both methods must be available, so that either of these modes of filling the balloons could be used under normal conditions, and the other only in an emergency.

The use of captive balloons without towing calls for appliances for winding them in, which, however, would add but little to the great difficulties above enumerated. The use of special balloon-carrying ships would remedy many of the before-mentioned evils; but these would have to be well enough engined to enable them to keep on with the rest of the fleet; and while they might receive coal or other fuel from transports, they still would require to start with and maintain a considerable supply.

In all, one sees even at a hasty glance that aerial craft present interesting and difficult problems for solution, before they can render much assistance to the navy in the present set of conditions. The same could, however, have been urged of torpedoes and of submarine boats; yet no one will deny the importance of the influence which both of these have exerted upon naval warfare and construction; an influence which is increasing in variety and amount from year to year.

How to Care for the Automobile Top

A good formula for renovating a black rubber or leather top from which the enamel has largely disappeared consists of liquid asphaltum, 1-8 gallon; outside finishing varnish, 1-4 gallon; boiled linseed oil, 1-8 gallon; castor oil, 1-16 gallon; coach japan, 1-8 gallon; ivory drop black, 3-4 pound. Mix these ingredients thoroughly together in a closed vessel to permit active shaking. After agitating the contents sharply for a time, add refined or pure turpentine in a quantity sufficient to bring the mass to a good brushing consistency.

A formula including beeswax is made of asphaltum, liquid form, 1-8 gallon; outside finishing varnish, 1-8 gallon; beeswax, 1 ounce; castor oil, 1-8 gallon. Bring to an intense black by the addition of a little drop black. Mix thoroughly and thin out to a brushing consistency with turpentine.

For a straight leather top with a worn and travel-stained appearance, but sustaining no fractures in its enamel, the following mixture will serve a good turn: Neatsfoot oil, 1-4 gallon; beef suet, 3 ounces; melted beeswax, 1 tablespoonful. Melt the oil and suet together, after which add the beeswax. Confine in an air-tight vessel, agitating same until a complete mixture of the contents is secured. Apply sparingly with a soft cloth and follow up with a clean piece of woolen, wiping clean and dry.

By way of information, it may be stated that all of the above dressings should be applied thinly and worked out smooth and uniform. With the exception of the last formula, all the materials should be brushed on, using for the work a flat bristle brush of soft joint and of a No. 1 quality.

For tops other than rubber or leather the use of tepid water and castle top mixture is recommended, applied with a soft, sheep's wool sponge, wiped dry with a wash leather, and then given an application of some good transparent renovator to render the fabric soft and pliable and fortify it against the ravages of service.

In case such renovators are not at hand the mixture of oil, suet and beeswax, already referred to, wiped on with a soft fabric of some kind and dried off carefully with a clean wad of woolen, will do very nicely. This dressing and the ready prepared renovators are particularly adapted for use upon the rubber-covered cloth top finished in a dull brown effect, and known to the trade as vulcanized carriage cloth.

The lining of the automobile top should also be cared for diligently. It needs frequent brushing with a whisk broom to flick out the dust and enliven the nap of the goods. These are small matters in themselves, but they prolong the life of the top.

Bavarian Government Using Motor Postal Wagons

The Bavarian Postal Department (which, as is not generally known, is entirely distinct from the Imperial German Postal Service) has a number of motor wagons for carrying packages from the railway station to the postoffice or *vice versa*. The frames of some of these are of the Daimler 1.5-ton type, the rear wheels being driven by gears. The motor is of 28 horsepower; has four cylinders, and is arranged for either benzine or benzol. The maximum speed with load is 11 miles per hour. The "box" holds more packages than that of the usual horse-drawn wagon. There are also similar and lighter wagons of the same type, with 1-ton frames, with motors delivering 16 horsepower, with either benzine or benzol. These wagons have chain drive and can make 17 1-2 miles an hour. Both types are supplied with solid rubber tires. The carbureter has piston type throttle regulation, delivering, according to the load, the requisite amount of air. In addition to benzine and benzol, the motor can also use heavy benzine. The circulation of the cooling water is effected by a centrifugal pump; the warmed water being cooled by a bee-hive cooler, aided by a fan. Lubrication takes place automatically by means of a pump forcing oil through channels cast in the three main bearings of the crankshaft. From these points it flows through the hollow crankshaft to the piston-rod bearings. The piston is also constantly lubricated, and the oil therefrom drops on the piston wristpin. The latter is hollow, so that the oil which is not used therein is led laterally to the cylinder walls. This system of lubrication does away with oil-tubes, and lessens the probability of choking. The oil consumption is said to be about four pounds per 100 miles.

The reduction gear is connected with the motor by a friction coupling; there are four speeds forward and one backward. The gears on the hind wheels are protected from mud and dust. The driving wheels are steel castings with the tires directly pressed thereon. The differential gear is also a steel casting; but all the other parts are drop forged.

COMMUNICATIONS FROM READERS MAINLY ALONG TECHNICAL LINES—THE NECESSITY OF TORQUE RODS; STEEL BALL IN CYLINDER TO PULVERIZE CARBON DEPOSITS; THE TESTING OF TIMERS, ETC.

Are Torque Rods Necessary?

Editor The Automobile:

[2,374]—I have an automobile of foreign manufacture and have constant trouble with the gear-box bearings and the universal joint behind the gear box. There are no radii or torque rods fitted to the car. Could you suggest a method of overcoming the default. F. E. D.

Larchmont, N. Y.

The fact that your car is not fitted with torque rods is sufficient to cause the trouble you experience. We should suggest your studying the accompanying diagrams and fitting rods that seems best adapted to your particular car.

Fig. 1 shows a back axle without any torque rods at all. The action of starting, stopping and going over inequalities of roads tends to push the axle forward, throwing all the strain on the pins of the spring shackles. If a rod were fitted to each side of the frame and attached at the rear end to clips on the rear axle this push or torque would be absorbed therein instead of in the pins. An easy method of fitting torque rods to cars that are manufactured without them is shown in Fig. 2 (the two top rods, however, are not absolutely necessary).

A method favored by quite a few manufacturers is shown in Fig. 3 here, it will be seen that the axle is held in tension forward near the gear box by tie-rods made from steel tubes; the axle in this case is allowed a small amount of movement backward and forward, but all harshness of shock is taken up in the springs above and below the rod. Another method of attachment of the torque rod to the frame is shown in Fig. 4. The same effect is obtained as in Fig. 3, the difference being that the attachment is held perpendicularly rigid with the frame instead of oscillating.

A substantial method of attachment is shown in Fig. 5; this type can easily be fitted to a car that is without rods. If necessary an extra cross member to the frame can be fitted to accommodate the front bracket.

Some cars use three rods to take the torque and thrust. Two rods are fitted from the axle casing to gusset plates hung from the frame at points in line with the universal joint behind the gear box, as shown in Fig. 6. A third tie-rod is attached preferably on the top of the axle casing to a point equidistant to the bottom rods. This will form a parallelogram of the rear construction suspension, allowing the bevel wheels to work always in the same plane, while with the other types shown the plane of the working of the axle in relation to the drive constantly alters.

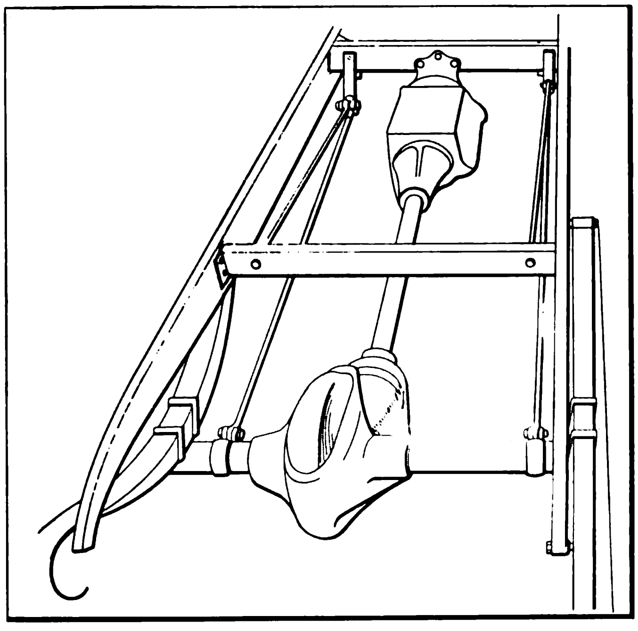

Fig. 2—Simple torque rods that can be fitted to cars that are built without any

A Sparrow Is Not Shocked When on Telegraph Wire

Editor The Automobile:

[2,375]—Please answer in the next issue of your paper why a person will not receive a shock when placing the hand on an engine after the current has passed through a spark plug?

2. Of what use is the compression chamber in a spark plug?

3. About what is the average difference in piston displacement to compression chamber in gasoline engines? L. S. Tuttle.

Eastport, L. I.

(1) The reason why a sparrow is not shocked when he perches upon a telegraph wire is because our feathery friend does not help to complete the circuit. Were the sparrow to put one foot upon the telegraph wire and the other upon the ground he would then be in shunt relation and would be shocked. The same is true of man and his relation to the spark plug. He must become a part of the circuit either in series or in shunt ere it will be possible for him to realize that the electromotive force delivered from a high-tension coil is sufficient to make him take notice.

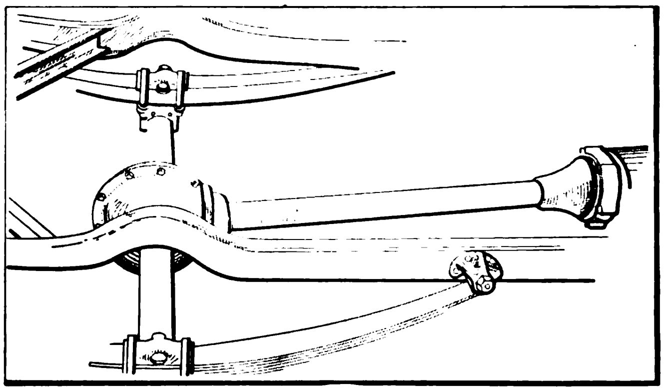

Fig. 1—Torque taken up in spring shackles and on tubular covering of driving shaft

(2) The compression chamber in a spark plug is the residence of pure mixture, and the same being pure it is ignited more readily, and the ignited mass shoots out of the chamber into the body of mixture in the combustion chamber, thus affording a wide distribution of flame, which, of course, adds materially to the value of the spark.

(3) This question is not sufficiently clear to permit one to say anything. The clearance space in the average motor is not far from 23 per cent. In racing types of motors it is higher; in "soft" motors it is somewhat lower. Perhaps you refer to the clearance space.

Suggests a Steel Ball to Pulverize the Carbon

Editor The Automobile:

[2,376]—Some time ago I wrote an article for your columns suggesting a steel ball in the combustion chamber as a remedy for

carbon deposits. A little later you wrote me that two parties had condemned the idea after using it. The idea was taken up in England, and if you care to look at the *Motor Car*, of London, of March 26 last, you will see what they have to say, and this is followed by a letter from a prominent user of an English car in the issue of the same journal of May 7 giving extended experience with the idea. I have also given the plan a severe trial and am sure that the steel ball, if not too small, will not get wedged in and injure the walls of the cylinder at all. It does the work and does no harm. I enclose you a recent letter from a party who has used it, but he did not know that by running the motor with one spark plug out for a minute he can blow out the ball easily. A. D. Hard, M. D.

Marshall, Minn.

The idea suggested has for its basis the use of a steel ball such as is ordinarily employed in ball-bearing work. The spark plug is taken out of one of the cylinders, and the steel ball is dropped in so that when the motor is standing still the ball rests on the head of the piston. When the motor is started and run, through the good office of the remaining cylinders, the ball is bounced around, bombarding the surfaces, with the result that carbon deposit is reduced to powder. After the process is conducted in this way the carbon powder is blown out through the spark plug hole, and if the motor is of the type that will permit of fishing the ball out the process may then be considered completed.

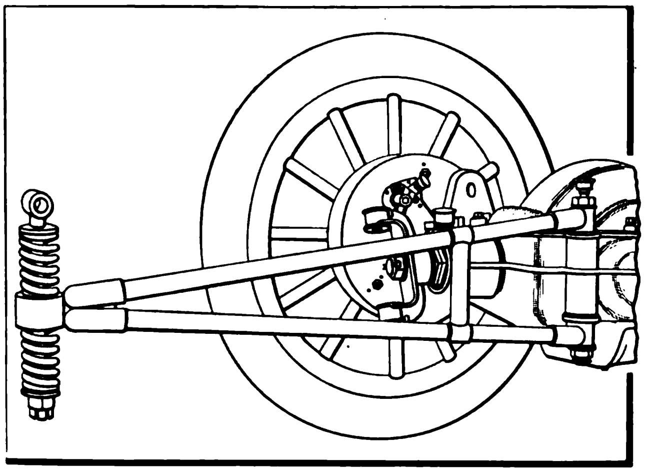

Fig. 3—The most usual type of torque rod used on early types of French cars

Wants to Know Why Timers Are Not Better Tested

Editor The Automobile:

[2,377]—My experience, which extends over three or four years, confined, to be sure, to substantially the two models of cars that I have owned and maintained, leads me to believe that the makers busy themselves with the more important matters to the detriment of the details. I am willing to concede that in the early days of automobile building there were so many kinds of trouble that it was necessary for the men who did the work to work on a basis of first come first served, and this applied to the troubles that arose as well as to the every-day matters. But the time should soon be here when the little things be given the attention they deserve. I would suggest that the wiring be better done, and that the battery installation be afforded a little discriminating care. Then, there is the timer. I have had a good deal of trouble with timers. Were the makers to test these little pests they would probably find that some of them are scarcely worth attaching to good motors. Reader.

Philadelphia, Pa.

This particular autoist has probably been so busy with his own trouble that he had very little opportunity for individual research beyond the limit of his own relatively restricted zone, nor did he go about among the makers sufficiently to find out just what they are doing. A visit to the various plants will probably show that the makers who expect to survive are testing out pretty much everything from raw material to accessories and with sufficient care to enable them to decide with some certainty as to the expediency of employing the materials and accessories that will come nearest to serving their purpose. It would be impossible to take sufficient space here to furnish all the evidence of activity that is available, but the following test of a timer as made in the Thomas laboratory at Buffalo will suffice to cover the point to be made:

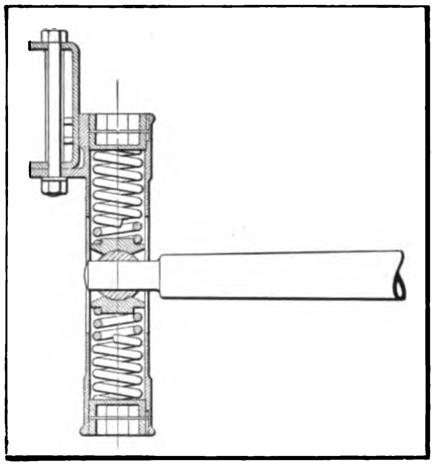

Fig. 4—Ball thrust at end of torque rod

This timer consists of both a primary timer and a high-tension distributor. The timer proper consists of a beveled wheel running in a V-groove cut in six hardened steel contacts, equally spaced in a fiber ring. The space between the contacts is touched only by the very edge of the beveled wheel. The wheel is held in contact by a lever or spring. The high-tension distributor is insulated from the timer by a fiber plate, and consists of a small ball mounted at the end of a light helical spring. The casing is of black fiber and equally spaced are six tool steel pieces flush with the bore of the fibers.

The small ball sweeps over each in turn, thus distributing the high-tension current to the proper plug. The shaft of the timer is mounted in two small ball-bearings. The advantage claimed by this timer is the large contact surface and long life.

The form of the wheel and bevel groove (both having the same angle) causes a certain relative slip, which is supposed to keep surfaces clean. The fact that the edge of the wheel only is in external contact with the case is supposed to prevent the picking up of dust and oil and depositing them on the contacts.

The timer was driven in a horizontal position by means of a small shaft journaled in two brass bushings. Two small universals connected the shaft to the 5-horsepower motor. The timer mounting was very rigid, and lined up so as to keep down vibration. The continuous counter on the ball-bearing testing machine was used to record the number of revolutions of the timer.

A Connecticut single-unit coil and six spark plugs were wired up as used in practice. Gould six-volt storage battery formed source of ignition.

Electric motor speed, 1,250 revolutions per minute, corresponding to 2,500 revolutions per minute on motor.

Reading on ball-bearing testing machine at end.........	2,936,000
Reading on ball-bearing testing machine at start........	1,500,000
	1,436,000

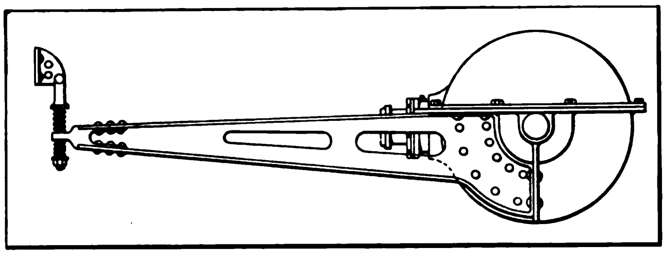

Fig. 5—Steel plate used instead of tube where a cross member of the frame prevents using a triangular type, as in Fig. 3

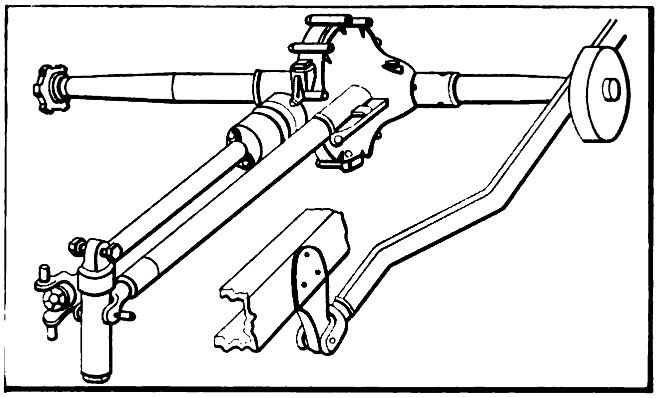

Fig. 6—Parallelogram formed by the three rods preventing any forward thrust

Ratio of speeds of motor and ball-bearing shaft practically 1 to 2.

Total revolutions per minute of timer = 718,000.

At 2,936,000 the lever holding the wedge-shaped wheel against the contacts broke and test was stopped. During running it was found next to impossible to get good, even sparking at speed of 1,250 revolutions per minute. Several different coils were used, but all with the same result. As speed decreased when circuit of motor was broken the contact would greatly improve. The timer cover was removed while the timer was being driven at 1,250, and a perfect shower of sparks was noticed; also bad arcing. The timer wabbled very badly and had considerable drag.

Upon examination the primary contacts were found to be worn badly in spots where it seemed as if the wheel had continually jumped and clattered. The high-tension ball and contacts were pitted, but not seriously.

The timer was lubricated well, but the results do not show it up as well as could be desired.

Wants Information of a Varied Character

Editor THE AUTOMOBILE:

[2,378]—I shall esteem it a favor if you will answer me the following questions through the columns of your paper:

1. What is good to remove tarnish on brass?

2. Is 31 teeth in the rear sprocket and 8 teeth in front sprocket the best gear ratio on an auto that has a two-cylinder opposed 4 1-2 inch x 4 1-2 inch, 12 horsepower engine fitted lengthwise in the machine and 28-inch wheels?

3. Is an automatic compression feed good to feed oil in crankshaft bearings to keep plenty of oil to splash, or is constant level either fed by a tank, the tank being airtight and oil flowing to a certain level in the crankcase from tank only as fast as needed.

4. Do you think that a radiator that has 28 tubes 5-8-inch diameter and 19 inches long, together with a three-gallon tank, will cool a two-cylinder engine 4 1-4 x 4 1-2; has a gear pump run by chain from crankshaft?

INQUIRER.

Galva, Ill.

(1) See page 536, this issue.

(2) The ratio of 8:31 should answer very well on your car for give-and-take roads, but there should be at least 13 teeth in the pinion.

(3) We do not understand what you mean by automatic compression feed lubrication. Whatever method you employ to keep a constant level in the base chamber should answer.

Feeding the base chamber through the bearings is better than direct to the crankcase. If the tank you use is airtight you must use pressure either furnished by hand or by the engine with a relief valve. If, however, you desire to use a gravity drip feed system you must have a vent in the top of the tank to allow the air in, otherwise the oil will not flow.

(4) Provided your radiator is in a position that the rush of air can strike it and the speed of the pump is fast enough, the amount of water and size of piping should give good results.

Questions That Arise

CONCERNING THE EFFECT OF HIGH VOLTAGE BATTERIES ON HORSEPOWER; PROPER METHOD OF OILING; SOME REASONS WHY METAL CLUTCHES SLIP, AND THE REMEDIES

[233]—Does the use of higher voltage batteries increase the horsepower of a gasoline motor?

This query can best be answered by publishing the following analysis of a test in which the engine used was a 40-horsepower, six-cylinder Napier, fitted with the maker's standard synchronized battery and coil ignition, the battery showing 4.8 volts. The engine was started up and allowed to run for some time so that an even temperature might be obtained.

The engine was first run and the horsepower taken for a period of two minutes, the average output shown being 40.9 horsepower for the period. A special coil was then installed, but the same accumulator used. The engine then gave 42.5 brake horsepower. The same coil was again employed, but the voltage was increased to six, and the conditions were otherwise unaltered. The power fell to 42 brake horsepower.

The same coil was again used with six volts, but the trembler blade was adjusted lighter than before. The same brake horsepower was registered. The trembler blade was then adjusted a little more heavily, and 8 volts used. The result showed 42.6 brake horsepower. The voltage was increased to 10 volts, the adjustment of the trembler blade remaining the same. The brake horsepower fell to 42.

The voltage was then reduced to 4, but the trembler blade was unadjusted. The brake horsepower rose to 42.2. The trembler blade was then adjusted a little more lightly and four volts used. The brake horsepower fell again to 42. The standard

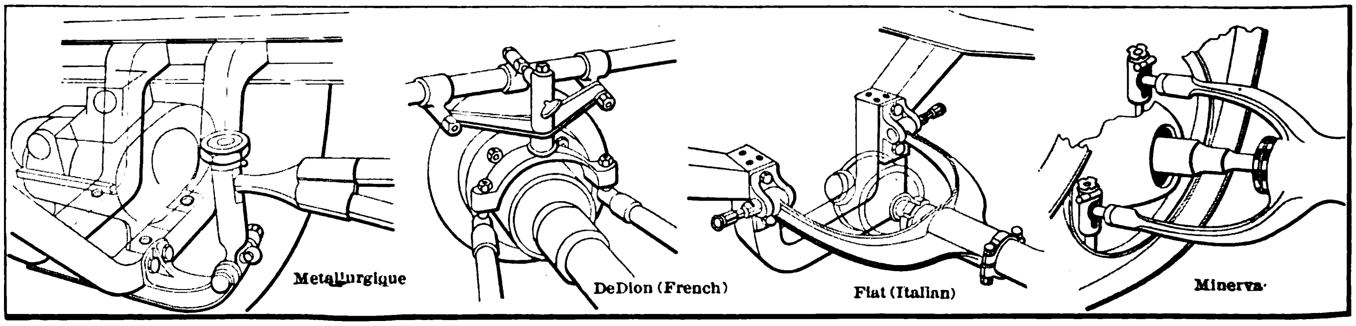

Fig. 7—Showing various foreign methods of attachment of torque rods, all intended to accomplish the same result

coil was replaced and an accumulator showing 4.2 volts fixed up. The brake horsepower registered was 42. The idea in going back to the standard coil with small voltage and special coil with small voltage again was to see whether any alteration had taken place in the engine itself. As the result showed, the brake horsepower still remained approximately 42.

The sum of the tests showed that the horsepower varied slightly from 42 brake horsepower, irrespective of the voltage rate, or whether the trembler blade was adjusted lightly or heavily. A main point, however, noticed was that at the lower voltage the engine ran with the spark very much advanced; in other words, for a given engine speed it commenced to knock with a less advance when using a higher voltage sooner than with the lower voltage.

This phenomenon suggests that nothing is gained by having a fiercer spark than that obtained from a fully charged battery showing 4 volts and means of varying the timing.

[234]—How much oil does a magneto require?

The accompanying sketch shows clearly the absurdity of pouring oil *on* oil holes instead of pressing the spout of the can into the hole and giving a drop or two. Besides, pouring oil all around the mouth of the orifice has the effect of coating the surrounding parts, so that they catch particles of dirt and dust which will eventually find their way into the bearing. Particular care should be taken in oiling such engine parts as valve rockers, pins and guides.

[235]—What is the customary rating of tires for various degrees of inflation?

The following tabulation is a near approach to average conditions:

INFLATION PRESSURE TABLE PER TIRE

Size Tire		Pound Load									
		200	300	400	500	600	700	800	900	1000	1100
		Pound Pressure Inflation									
3	inch	45	55	65							
3 1-2	"		50	60	70	80					
4	"				65	75	85	95	105		
4 1-2	"					70	80	90	100	110	
5	"						75	85	95	105	115

The following table has been compiled by a well-known tire concern and represents about average practice:

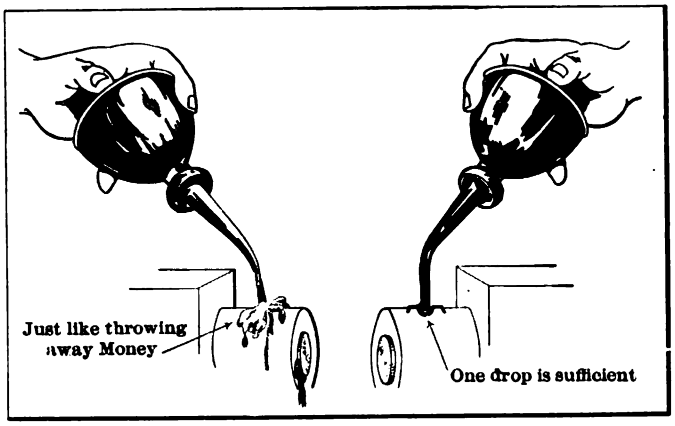
Size Tire		Front Lbs. Pressure	Rear Lbs. Pressure
3	inch	70	70
3 1-2	"	60	70
4	"	70	80
4 1-2	"	80	90
5	"	100	110
6	"	120	130

[236]—What are the different causes of metal clutches slipping?

(1) Incorrect lubrication causes slipping, or abrupt engagement. To remedy this, empty the clutch of all lubricant and fill with one pint of kerosene, screw up vent plug, start engine and run for two or three minutes, letting the clutch in and out several times so that the kerosene can clean the interior faces of the plates. Thoroughly empty and wash out with a small quantity of gasoline. An excellent lubricant that will be found to give good results is a mixture of two-thirds medium engine oil and kerosene. To mix these together take a vessel and pour the oil in first and the kerosene afterwards and with the use of a syringe work the two together for a minute or so before injecting.

(2) Plates worn too shiny and thin. Replace the very thin ones by new ones and rough the others up slightly with emery paper. The cause of a new plate clutch being harsh is that the surface of the plates is too rough; this should soon wear off. Wear on the plates sometimes allows the inside nuts to bottom against the case, completely counteracting the action of the spring; filling the heads of the nuts will sometimes remedy this temporarily, but as soon as new plates can be obtained they should be inserted.

(3) Deposit of metal particles secreted between the plates, preventing proper adhesion. Remedy same as No. 1.



There is a wrong way and a right way of oiling—both are here shown

(4) After an adjustment the pedal arm touches against the groove in the floor boards, preventing the clutch from getting its full thrust.

(5) Some makers do not put a universal joint between the clutch and the gear box; the whip in the frame going over bad roads has a tendency to make the clutch slip. The same applies if the alignment of the above-mentioned organs is not correct. A universal joint between them will remedy this.

(6) The thrust bearing on the clutch fork should be kept well lubricated, otherwise the operation of the clutch will be uneven. Unless this operation is effected automatically it should be attended to at least once every 100 miles, and oftener for traffic driving.

[237]—Is loss of compression ever caused by rotary motion of piston rings?

After an engine has been run for some time it may be found that it loses compression and one naturally looks to the valves for the trouble. After all the carbon has been removed from these and they have been carefully ground in, there is still a falling off in power. Providing the gasket-joints are tight the cause of the trouble can be expected to lay in the piston rings. Upon dismantling the cylinders the pistons and rings will be found to be scored in places, which indicates that the compression has been leaking past the rings. The only remedy for this trouble is new rings. Great care should be taken to make these a good fit in the slots and the utmost distance between the ends when compressed should not exceed 1-64-inch. It has been found that this does not always stop the leakage. It is thought that the force of the explosion gives a slight rotary action to the rings so that the slots come into a line, allowing the gases to escape.

If the slots are cut step-fashion no amount of rotary action will affect the loss of compression through the position of the rings, provided these fit well in their grooves and join well together.

As piston rings are made from hard cast-iron, great care should be exercised taking them off and replacing them. To insert the piston into the cylinder it is necessary to compress the rings by hand and unless the cylinder is lowered slowly one is liable to pinch the fingers between the knife-like edge of the ring and the cylinder base.

[238]—What is the correct way to stand to start a car?

Stand perfectly square, facing the radiator; to accustom yourself to this position take the left side of the frame in the left hand, the starting handle in the right; pull *up* smartly if coil is used; when the handle is at the topmost point pull it towards you so that it disengages from the jaws or pin on the engine. Be sure that the elbow is kept well out when swinging the handle for starting on the magneto; if not a backfire may force the arm between the upcoming handle and the side member of the frame, causing either a broken or dislocated thumb, wrist or elbow. Practice this position with the current off several times after watching an experienced man start the car.

Keeping the Bright Work Up

M. C. HILLICK TELLS HOW TO KEEP THE METAL PARTS OF A CAR UP TO STANDARD: GIVES OTHER ADVICE

TO maintain the brass and nickel furnishings of the automobile in a bright, clean condition constitutes no small share of the caretaking of the car. There are plenty of simple formulas and ways for brightening up the brass fixtures, but some are more or less ineffective and others are harmful to the metal, especially after the lacquer becomes worn away. Following are some good and effective ones: To remove dirt, tarnish and corrosive accumulations from the metal parts while the lacquer remains in a good state of preservation use a mixture of 5 parts of whiting and 3 parts mutton tallow. Another formula consists of dissolving 8 parts refined soap in 10 parts of warm water, after which add 30 parts of whiting.

Again, add to every 2 parts of sulphuric acid 1 part pulverized bichromate of potash. Mix the two ingredients thoroughly and dilute with water equal in weight to the acid and potash. To use this polish wet over the brass with it, wash at once in clean water and wipe dry immediately, then giving the brass a light polish with rotten stone under a piece of chamois skin.

Another formula is made up with 60 parts carbonate of magnesia and 1 part ferric oxide, mixing well together. Moisten a soft woolen cloth with denatured alcohol, dip in the powder, rub the metal smartly and dry off with a soft leather or clean woolen cloth.

In case the brass or metal is to be refinished it will first be necessary to remove the old lacquer completely, which may be accomplished as follows: Mix 4 parts denatured alcohol with 1 part ammonia. Dip a woolen cloth in this fluid and then dip the cloth in tripoli, rubbing hard and firm. After removal of the lacquer, polish and clean with a mixture consisting of 4 parts of refined soap and 3 parts rotten stone. Dissolve the soap to a thick glue consistency, stir in the rotten stone and then reduce to a heavy liquid consistency with turpentine.

Another formula for this work is made up by mixing 5 parts pulverized chalk and 4 parts tripoli powder mixed to a rather stiff paste in melted beef and mutton tallow, equal parts.

For large garage or paint shop work where a considerable amount of brass and other metal parts are to be cleaned it will be necessary to provide for handling the work with greater expedition. To accomplish this, arrange two tanks of wood, copper lined, with a coil of steam pipe in each and each tank of 60 gallons capacity. Into tank No. 1 pour 50 gallons of water, to which add 6 pounds of lye or caustic soda.

In tank No. 2 pour a like quantity of water, to which add 1 1-2 pounds oxalic acid. Before placing the brass in the lye or caustic soda solution turn the steam into the pipe long enough to heat the water close to the boiling point. Let the brass parts remain in tank No. 1 sufficiently long to remove the lacquer, whereupon proceed to transfer the brass to tank No. 2, into which the steam has previously been turned until the solution is very hot. This solution after a short immersion will serve to remove the tarnish from the brass and to neutralize the effect of the lye or caustic soda. Upon removal of the brass from tank No. 2 it should be at once wiped dry with clean woolen cloths and either polished to a high luster with some one of the polishing preparations named above or put upon a buffing wheel and buffed to a high polished condition. In lieu of the lye or caustic soda solution a dip may be provided by mixing 2 parts of sulphuric acid with 1 part nitric acid by volume or liquid measure. A tank lined with heavy sheets of lead will be necessary to hold this acid mixture in confinement. A room specially equipped and set apart for this work will be found essential in order to dispose of the brass and metal equipment on a large scale.

As soon as the brass is polished or buffed, as the case may be, it should be dusted off carefully and in a clean warm room coated with lacquer made and sold expressly for this purpose. If this lacquer is not at hand a substitute lacquer may be provided by letting down white shellac to a very thin state with denatured alcohol. A thin crystal white varnish also makes a very good substitute in emergency cases.

Statuary Bronze Finish for Brass

In connection with the above it appears that a considerable following of automobile owners and users is taken up with the statuary bronze finish for brass parts. This style of brass finish has proved exceedingly popular with railway companies and their patrons throughout the country and the manufacturer of automobiles and automobile accessories may even incline to its use. To work out the statuary bronze on smooth highly polished brass prepare a No. 1 solution consisting of 1-2 ounce of liver of sulphur, or, in the language of the chemist, sulphuret of potassium, added to 1 gallon of water. Maintain this solution in a hot state by confining in an earthen crock set into a vat of hot water to within a couple of inches of the top of the crock.

Solution No. 2 is made of 1-8 gallon sulphuric acid and 10 gallons of water, cold. First, clean the brass parts in a potash solution. Then rinse in clean cold water, from which bath it is transferred to the No. 1 solution and then on to the No. 2 solution. In case of yellow brass this dipping first in solution No. 1 and then in solution No. 2 will have to be repeated several times or at least often enough to develop the desired bronze effect.

A sand blast operated by a compressed air or a stiff wire wheel brush should be operated, upon which the oxidized brass may be used to bring out the color uniformly over all the surface of the brass. In the case of yellow brass, of smooth finish, after giving it an acid dip it should be put on the wire wheel brush to give it the desired mat. Yellow brass having less copper in its composition than the brighter, lighter brass, is acted upon slower than the latter and it therefore oxidizes slowly. Dip in No. 1 solution, then at once in No. 2 solution, then rinsed, first, in cold and, second, in hot water and finally dried in sawdust. Next it is worked upon the scratch brush, after which it is for a second time put through the entire operation, thus furnishing an attractive bronze finish.

In brass finish there are apparently different compositions of metal such as, for example, high yellow brass, old brass, red brass and so on. To overcome the disadvantages incident to working out a uniform color and finish on these various styles of brass many railway companies copper plate all the brass parts, thus giving them a uniform color to oxidize upon. The brass parts having a dead finish need only to be acid dipped to make them conform to the color of the remaining brass and give them the statuary bronze finish.

A single immersion in the No. 1 and No. 2 solution will suffice, as a rule, to give red brass or any brass or other metal low in its proportion of zinc its proper degree of oxidized effect.

With either kind of brass when the fixtures are taken from the No. 1 solution they should be taken on through the No. 2 solution, this latter being necessary to bring out the desired oxidized bronze effect.

This exceedingly popular green effect is developed by using, for work to be handled on a large scale, 30 gallons of water, 3-8 gallon stale beer, 1-8 gallon acetic acid, 1 1-3 quarts vinegar, 4 1-2 pounds rock salt, 9 1-2 pounds sulphate of copper and 2 1-2 pounds sal ammoniac. Dissolve these ingredients completely and mix thoroughly, using in a cold state. Clean carefully the copper or brass surface, then immerse in the solution for 10 or 15 minutes or long enough, in fact, for the dark corrosion to show itself. Then remove from the dip and with a stiff bristle brush proceed to stipple the surface by tapping softly with the point of the brush not only to produce the mottled green effect, but to prevent the runs which might otherwise show in the finish. Avoid using the green too strong. The proper surface condition should be a dark field with the beautiful green showing through in the form of a mottled effect.

After dipping and stippling the brass should be exposed to the air for, say, half an hour, during which time the wonderfully soft, lustrous green will come forth.

Permit the surface after this treatment to dry thoroughly, at the expiration of which time apply a very thin coat of lacquer or some practically transparent substitute for lacquer. This thin protective coating serves the double and indispensable purpose of protecting the finish from change at the same time yielding the greenish yellow shade, which, on the dark ground work, is esteemed the truly fashionable and quite the most correct and best antique.

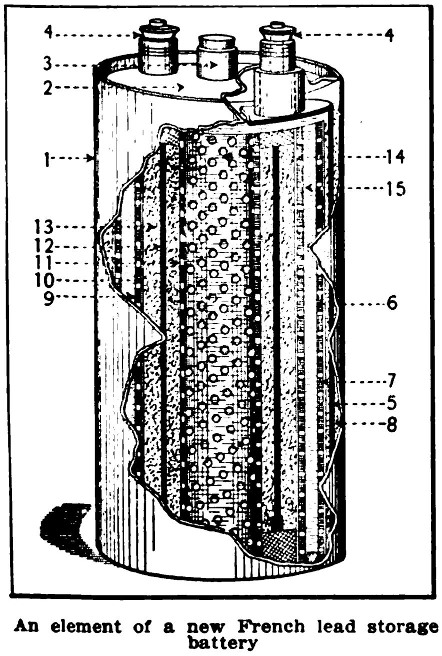
By way of a concluding word, it may be said that these formulas will necessarily have to be worked out with the explicit understanding that materials do not always act the same, being very sensitive to prevailing conditions and to methods of handling.

Digest

BRIEF RESUME FROM FIFTY FOREIGN JOURNALS—NEW FRENCH STORAGE BATTERY GIVING INCREASED LIFE AND CONSTANT CAPACITY—"CONGRESS OF THE CHILL" IN VIENNA—DIRECTIONS FOR QUICKLY DETECTING VANADIUM IN STEEL

Each element of a new French electric storage battery, called the Phoenix, weighs 4.545 kilograms and a vehicle battery composed of 44 cells in a rectangular tray weighs 200 kilograms, plus the weight of the tray, which varies according to the requirements. According to trials the useful capacity of a battery of this size reaches 36 watt-hours per kilogram of total weight, or 7,200 watt-hours for the battery. An estimate of the cost of operating and maintaining a taxicab equipped with this battery is based on 120 kilometers of travel for each charge and is placed at 18.40 francs per day, as compared with a cost of 28.43 francs for operating a gasoline cab the same distance each day, under conditions of city traffic. The component parts of a cell are enumerated as follows:

(1) A cylindrical casing usually made of ebonite of special quality and somewhat elastic, marked 1 in the accompanying illustration. (2) A conductive grid 5, made of lead or a non-corrosive alloy and formed of a lower ring provided with thin bars of the same metal extending vertically upon the circumference of another ring which serves for support. (3) A cylindrical vessel of ebonite, perforated with holes 6. This vessel is covered exteriorly with a layer 7 of cellulose capable of absorbing liquids and offering only small electric resistance while preventing active matter from penetrating to the vessel. Between this perforated vessel and the exterior layer there is a cylindrical space in which the conductive grid 5 is placed. (4) A second conductive grid 12 similar to the first one and placed in the interior of a second perforated vessel. (5) The second perforated vessel 9, similar to the first one, but of course of smaller diameter so as to leave a free circular space where the second conductive grid is lodged. Like the first perforated vessel it is covered with a layer of cellulose permeable to liquids.



An element of a new French lead storage battery

The space between the casing and the first perforated vessel and containing the first conductive grid is filled with the positive active matter 8. The negative active matter 13 is placed in the annular space containing the second conductive grid; that is, between the two interior vessels 9 and 11. The electrolyte occupies the free spaces 14 and 15. The upper ends of these two annular spaces containing active matter are closed by means of a rubber ring, while a cover 2 made of insulating material closes the upper opening of the enclosing layer of cellulose and is formed with a central aperture closed with a rubber stopper which is removed during charging to release the gases developed, and the electrolyte is introduced through the same aperture. Each of the two conductive grids carries a stem which passes through the cover of the cell, constituting the positive and negative electrodes 4. The construction is believed to obviate all dropping of active matter to the bottom of the cell, and resulting short-circuiting, and also all buckling of grids by simpler means than are employed for the same purposes in the ordinary lead-lead batteries, the reasons for this belief being given in the article. In the ordinary battery the dead weight caused by materials which serve only the purpose of safeguarding its functioning reaches a figure which reduces the capacity of the battery as a whole to 7 1-2 ampere-hours for each kilogram of battery weight, while in the Phoenix, invented by a Mr. Genard, the active matter constitutes 42 per cent. of the whole weight, and the capacity is thereby raised to 14 ampere hours per kilogram. At the same time the active matter in Genard's battery contains only pure and dry oxides of lead, while in other batteries admixtures of glycerine, magnesium or asbestos are resorted to for purposes of strength.—*La Vie Automobile,* Aug. 27.

The second "International Congress of the Chill," as it is picturesquely called, being a congress for the consideration and advancement of methods for chilling or cooling, will be held in Vienna, October 6 to 11 next under the patronage of Archduke Leopold Salvator. The first was held in Paris in 1908. Hence the name *Congrès International du Froid.* The subjects for discussion are divided as follows: (1) the science of cooling; (2) industrial production of coldness; (3) chilling in alimentation; (4) chilling in other industries; (5) chilling for transportation purposes; (6) administrative and legislation. A program for discussion, aside from the ordinary grist of papers and memoirs, has been worked out by the *Société Internationale du Froid,* whose address is 10 rue Denis Poisson, Paris, and the subjects will relate largely to processes of cooling not widely understood or known, it being the object of the society to stave off lengthy academic discourses. Chilling methods used in the chemical industry, which were neglected at the first congress, will be treated fully in the regular papers.—*Le Génie Civil,* Sept. 3.

For cheap aluminum castings a 33 per cent. zinc alloy with fusion point about 470 degrees centigrade is preferable, but for castings which must be particularly light and are subject to considerable deformation stresses an alloy with copper, though much more difficult to cast, meets the requirements better. There must first be made an alloy of 50 per cent. copper and 50 per cent. aluminum, which requires high heat and causes the formation of oxides and ashes. Commercially pure aluminum is added afterward, until the copper content is reduced to about 7 per cent., and the alloy has then a fusion point between 560 degrees and 622 degrees centigrade.—J. L. Jones quoted in *Chemiker Zeitung*, June 21.

A rapid chemical method for ascertaining the presence of vanadium in steel is described by Paul Slawik. It is based on the fact that a brownish-red coloration is displayed when vanadium salts are acted upon by peroxide of hydrogen. The author gives these directions: Dissolve 0.25 grammes of the steel to be examined in 4 cubic centimeters of nitric acid of density 1.20; heat; add about 0.3 grammes of persulphate of ammonia. There follows a discharge of gas. Heating is continued until this discharge ceases. Then the solution is cooled. There is added 3 to 4 cubic centimeters of phosphoric acid of density 1.30. The yellow coloration due to the iron ceases and the liquid remains only faintly rose colored. Shake. By means of a pipette 3 to 4 cubic centimeters of peroxide is poured into the test tube slowly so only thin films of the two liquids are mixed at the point of contact. In the zone of contact there is now formed, if vanadium is present, a brownish-red ring. As little as 0.01 per cent. of vanadium can be detected by this method. By comparison with samples of steel whose vanadium content is known, and which are treated in the same manner, the vanadium content can be approximated. The author uses a volumetric method, which he describes, for exact quantitative analysis.—*Chemiker Zeitung*, June 21.

The manufacturers of the Gnome revolving motors have submitted a new type for test at the laboratory of the Automobile Club of France. It has four vertical cylinders and burns kerosene, having a Longuemare kerosene carbureter.—*Bulletin Officiél*, July.

The German Acetylene Society has arranged a six-day course in Berlin at which blacksmiths and welders may learn all there is to be known in practice about autogenous welding. The pupils work eight hours each day. A program of the tuition is given.—*Metall Technik*, August 13.

Don't

A FEW ADDITIONAL INJUNCTIONS TO THE TYRO AND THE EXPERIENCED AUTOMOBILIST THAT MAY STAND THEM IN GOOD STEAD IF CAREFULLY READ, REFLECTED UPON AND DIGESTED INWARDLY

Don't blame the magneto for carbureter troubles, and unless you understand the interior workings of the magneto don't take it apart.

Don't drive friends' cars unless it is necessary. If anything goes wrong you will surely be blamed.

Don't leave a car standing in the sun when it is possible to put it in the shade.

Don't use an open exhaust in towns or near houses in the country late at night; you have no right to disturb other people's sleep.

Don't think that the cheapest policy of automobile insurance is the best: what you insure for is that in case of accident you will be paid.

Don't underestimate the mileage of tires when obtaining an adjustment on tires. The tire companies from long experience know almost exactly what mileage a tire has run, and you are more likely to obtain better treatment by telling the truth than by underestimating.

Don't drive fast over loose stones. Better come down to a lower gear; it eases the engine and saves the tires from deep cuts.

Don't blow your horn immediately behind someone crossing the street or about to cross, if they have not seen you; either stop or give audible sound of your approach before you get to them.

Don't pass by horses fast on country roads; they may not be used to autos and the noise just behind them may make them swerve the wrong way.

Don't trust to luck. There is no such thing from the automobile viewpoint.

Don't rely entirely on the guidance of country people. Find out the way before you start: then you will know if the country people are giving correct information.

Don't fail to look at the level of the gasoline every time you go out: it does not take long and the habit may save you hours' delay.

Don't ask a friend to act as expert in the purchase of a used car: if it turns out wrong you will probably lose a friend. It is better to pay an expert who has spent years in acquiring knowledge.

Don't indulge in races on the high road. If another driver wants to pass you, let him; and if you want to repass him, he will probably let you.

Don't despise help proffered. If you don't want it, say so graciously; it costs nothing more to be polite.

Don't forget to take the number of a car in the following cases: Accident to yourself; to others; if you lend another autoist anything, or if you borrow anything from one.

Don't tinker with a car for want of something else to do; unless there is something wrong, leave well enough alone.

Don't go out without a spare shoe, inner tube, jack, pump, soapstone powder, tire irons, screwdriver, adjustable wrench, copper wire, insulating tape and cotton waste.

Don't take it for granted that a vicious chuck-hole won't snap the neck of a passenger in the tonneau simply because it does not affect the driver.

Don't ask a guest to read the road map and then blame him if you land eight miles outside gasoline control.

Don't drive fast around corners; the time you save by not slowing up, compared to the loss of rubber on the rear tires, is not worth it. Collisions do not often happen on straight stretches of road.

Don't sit in the car and smoke cigarettes while the passengers are pumping up tires. It might give wrong impressions.

Don't forget when passing a car that has pulled out for you to admit that you have brushed elbows with polite society.

Don't assume too much. Perhaps within a mile you may require the services of the farmer whose wheel you tried to take off.

Don't try to talk yourself out of obvious conclusions: A dead pig in conjunction with 35 miles an hour is an obvious conclusion from the farmer's viewpoint. Settle.

Don't try to argue constitutional points when a braced log-chain is athwart the radiator and its proprietor has the floor. Back away.

Don't allow your publicity man to dope out any old thing just to show that he's alive. Make him wait till he has something to say. If he waits too long, nudge him.

Don't consult the posters for information about a coming track meet. What they say is liable to be biased.

Main Building Exterior

Assembly Room

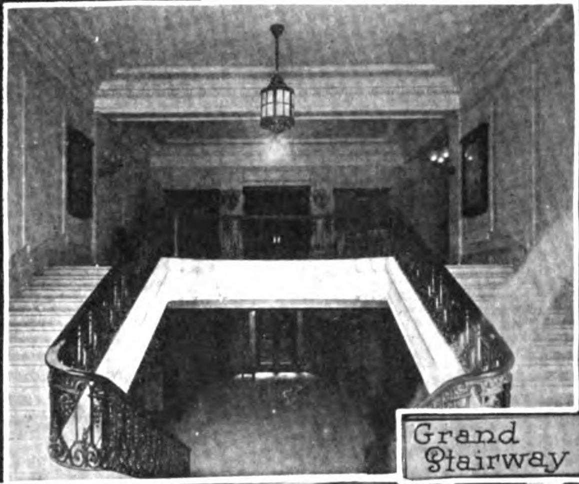
AUTOMOBILE CLUB of AMERICA

VIEWED from the vantage point of international affairs, there is no automobile organization in the United States in the same class with the Automobile Club of America. Aside from being the pioneer body in the New World devoted to motoring, this body has always occupied the leading and representative position as affecting the automobile in America in its relation with motoring all over the world.

Through its offices and machinery the American autoist who takes a tour in foreign lands is afforded advantages and conveniences that cannot be equaled. As a matter of reciprocity, the foreign motorist who wishes to tour in America finds equal advantages if he is duly accredited to the Automobile Club of America through his home organization.

From its inception this club has been a leader in everything tending to develop interest in motoring and the motor. It originated the first automobile show and conducted all the pioneer enterprises of the kind in the metropolis until the idea had be-

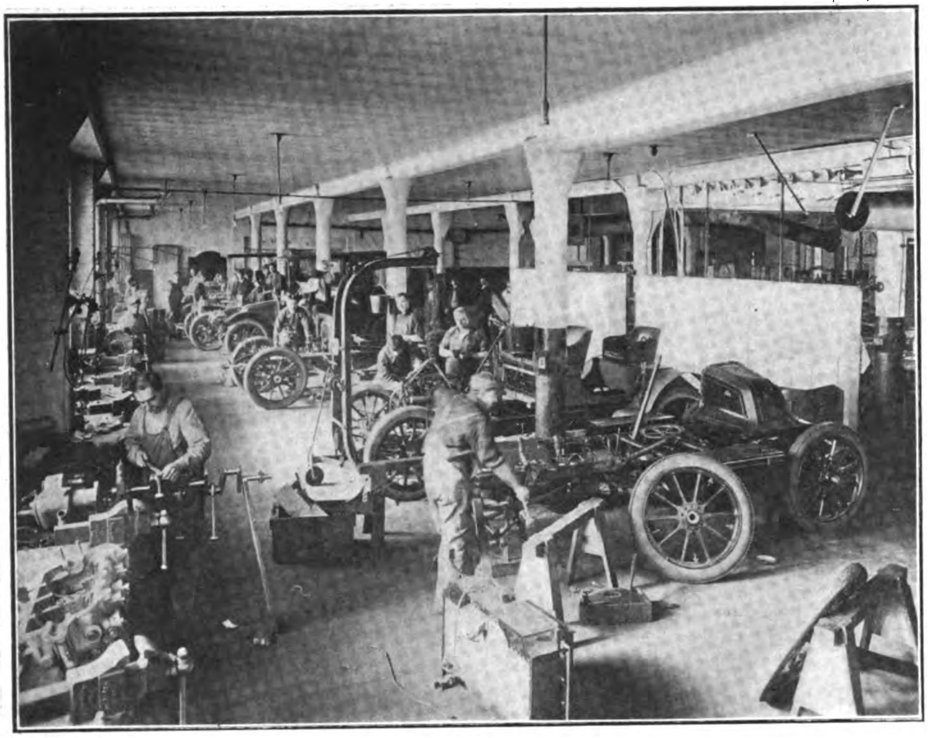
Common Room



Grand Stairway

Directors Room

Grill Room



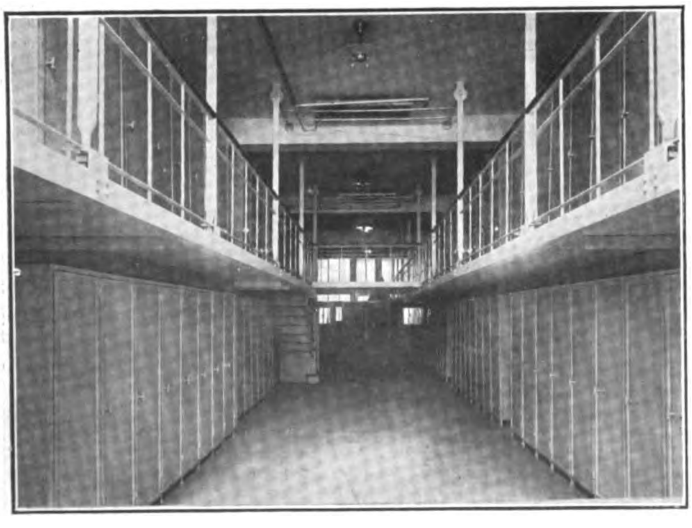
One-twelfth of the repair shop conducted by the club

come firmly implanted and had grown so as to cover the whole continent from Saskatoon to Buenos Ayres.

Its first show, conducted ten years ago, proved an instantaneous success, all space being taken by exhibitors many months in advance of its opening. There were sixty-nine exhibits and Madison Square Garden was crowded throughout the continuation of the show. One of the rules governing the affair sounds strange at this period of motor development. There was a track measuring one-eighth of a mile and the rule prohibited speeding upon it, owing to the sharpness of the curves. In spite of the speed limit imposed various kinds of tests were carried out upon the track. These included starting and brake tests and obstacle contests for steam and gasoline vehicles.

From this beginning the system of national automobile shows as it exists to-day has been evolved.

The club conducted the first endurance run ever held on American soil and for years was the main factor in automobile racing. As an organization it held its first sociability run November 4, 1899, when the club members gave a parade from the Waldorf to Hotel Claremont and return, and during its first year of existence it conducted seven short runs with much pleasure and success.



One-sixth of the locker corridor available at A. C. A.

The first racing event that attracted attention was the Blanchet Cup contest, which was won by A. L. Riker, but during the first year of its life several minor racing events were conducted.

One of the most important of the club's activities was inaugurated shortly after its birth, when the foreign relations department was instituted. At that time there were only seven recognized automobile clubs all over the world and foreign touring was almost a negligible quantity. To-day there are sixteen clubs forming the International Association of Recognized Automobile Clubs, one from each of the chief nations of the world, and the Automobile Club of America is the representative of the Western Hemisphere in its councils.

Each year from 3,000 to 4,000 Americans desiring to tour abroad are given the advantages of the club in this regard and about as many foreign tourists are received and entertained by the club. Customs, bonding, licensing and registration are all attended to, and through the introduction of the club the tourists are placed in possession of voluminous data and information with regard to travel. Owing to the fact that automobile regulation in the United States is under State and not Federal jurisdiction, several foreign countries cannot make agreements covering the exigencies of travel because they are not empowered to treat with individual States. This difficulty is obviated by the club through its relations with the Royal Automobile Club of Great Britain, which assumes to act as intermediary in customs and bonding matters where the legal obstacle referred to is interposed.

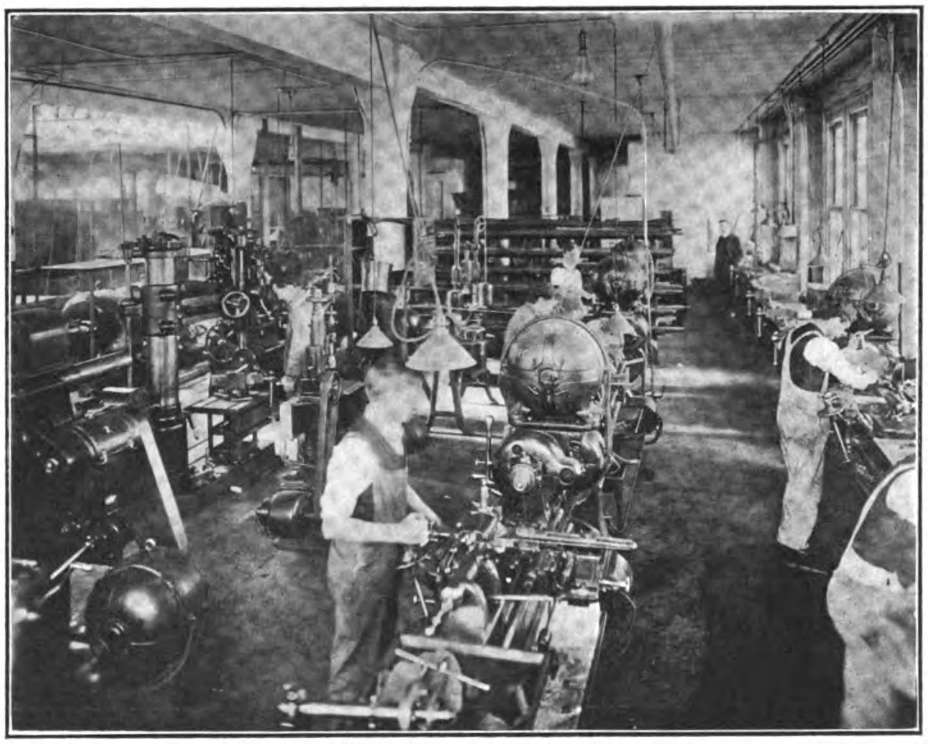
Before its first year was ended an endurance run to test the reliability of the automobile was proposed for the following Autumn.

This run developed into the famous New York to Buffalo event, which was called off at Rochester after the assassination of President McKinley. The conditions of this run seem strange when viewed from the modern point of vantage. The awards were based upon average speed. There were 87 entries and 82 starters, including several commercial delivery wagons and trucks and a few motorcycles. They were classified by weight and in night controls the entrants were allowed to make as many repairs as they pleased. This feature of the contest was provided for by the entrants by the shipment of quantities of parts and supplies to the control points, and there was a busy scene each night of the run after checking in.

On the way up-State the contestants went through a hill-climbing event on Nelson Hill, near Peekskill, N. Y., but the showing of the cars did not count in the general result, as the hill climb was regarded as a separate contest.

In 1902 the club conducted a reliability run to Boston and return, 488.4 miles. In this event the present general principles of the rules which govern reliability contests were outlined and foreshadowed. There were 80 entries and 75 starters in this tour. Of these 68 finished and 17 had clean scores.

The show feature continued to grow amazingly in patronage and interest and the club expanded along all lines of activity. The following year the feature was a commercial vehicle run of 100 miles over the streets of New York in which there were 13 entries. Good roads generally had been a prime object of the club from its inception and by this time the club had gained a strong foothold and exerted a powerful influence in many enterprises that have since developed into practical fruition. A dozen projects, all aimed to improve the highways, were fathered by the club and several of them are in existence to-day.



One-sixteenth of the space devoted to machine shop

The various sporting and pleasure events given under the direction of the club since its inception are too numerous to mention. While the club still maintains its place in sport, it has a wider field and one of vastly more importance to the generality of motordom.

It is headquarters for everything that is affiliated with the automobile in America.

The club was formed June 7, 1899, with General Avery D. Andrews at its head and was formally incorporated August 16 of that year. Its first quarters were at the Astor. George F. Chamberlain acted as head of the new organization, but was not formally invested with the title of president. Aside from its official interest in sport, the club went in for social diversion and educational pursuits in its earliest period to a greater relative extent than at present. The good roads meeting held during February, 1900, proved astonishingly effective in bringing the conditions of the highways to general notice. Precisely the same arguments were used by the speakers in addressing the club that are used now with so much force to prove the many and varied advantages that result from passable highways.

Albert R. Shattuck was elected president at the annual meeting and served with distinction then and subsequently. The club soon grew to 200 members and continued to expand in all directions, making particularly great strides during the administration of Elbert H. Gary, which terminated last April. Judge Gary, chairman of the board of directors of the United States Steel Corporation, devoted much immensely valuable time to club affairs and the effect of such labor is everywhere apparent in the structure of the organization.

The present officers of the club are as follows: President, Henry Sanderson; second vice-president, Robert Lee Morrell; third vice-president, Edward Shearson; treasurer, Finis E. Marshall; consulting engineer, Schuyler Skaats Wheeler; chaplain, the Rev. Wilton Merle-Smith, D.D., and secretary, Charles E. Forsdick. John E. Borne was chosen first vice-president of the organization at the last election, but death removed him since the date of election.

The quarters of the club are the most magnificent in this part of the world, at least, that are used for similar purposes.

The buildings are located between Fifty-fourth and Fifty-fifth streets west of Broadway. The main building was completed in 1906 and fronts eight stories high on Fifty-fourth street. Its carved-stone front and superb entrance give the impression of luxurious magnificence that is borne out in detail by inspection of the interior. Through a great marble hall the visitor finds entrance to the building. At the far end of this hall the way leads up a broad sweep of stone stairs to the main floor. At the head of the stairs a broad door shows the way to the grill room, restaurant and dining room of the club, while to the left is the general assembly hall, one of the finest rooms of its kind in New York or elsewhere.

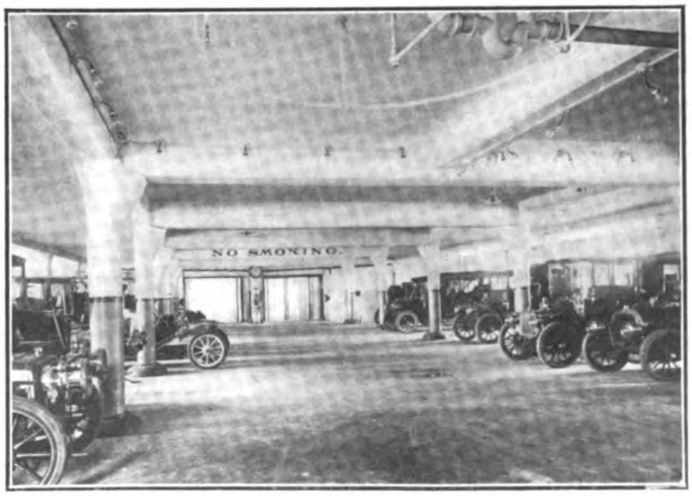
Chaste columns uphold the ceiling which is so high that it seems a little dim and shadowy except in the blaze of artificial light. The floors are of polished hardwood and equal in point of space any unbroken floor surface, except in one or two of the largest hotels in the country.

Save for the fact that the bureau of tours will be quartered on the first floor when the new building is thrown open, there will be no changes on the first and second floors of the main building. The third floor at present contains the administrative offices, the executive offices and several of the department headquarters. When the new building is occupied the rooms on the third floor of the old structure will be thrown together and will be occupied by the supply department, which has grown in size and importance until it now demands more room.

The fourth, fifth, sixth and seventh floors of the old building will not be changed in any respect, except that they will be connected with their corresponding floors in the annex. They are used as the garage and each floor will be equipped with a turntable and every other modern facility for the care of automobiles.

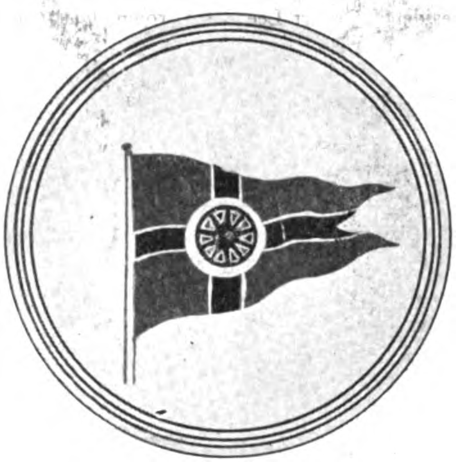
In the new building the eighth floor will be added to the garage equipment of the club, and in the corresponding level of the old building, which is now used as a machine shop, the partitions will be knocked out and it will also be a part of the garage, making five full floors that will be devoted to this purpose.

The new building is twelve stories in height, with a roomy and conveniently situated basement. In this basement the dynamometers of the club, of which there are two, one to test the cars and other motors, will be installed. Back in 1904, Mr. Wheeler, consulting engineer of the organization, was asked to design and build apparatus to determine the performance of cars of all kinds, and the machine that he devised was installed in 1908. It is



One-third of the live-storage room of the club

President Henry Sanderson



Emblem of the A. C. A.

Robert Lee Morrell, Second Vice-Pres.

equipped with many ingenious accessories for measuring force and speed and the advantage claimed for it is that it is possible to test a car in an hour or two and reach more definite results than by a road test covering much longer periods.

The motor dynamometer was installed in July, 1910, and was described briefly in a recent issue of THE AUTOMOBILE.

The technical committee will also be quartered in the basement.

The ground floor of both the new and the old buildings will be used largely as an entrance and exit for automobiles. The cars will enter from the Fifty-fifth street side and will leave from the Fifty-fourth street side.

The second floor of the new building will be for the chauffeurs. Every convenience will be afforded them except sleeping quarters and the arrangements planned for this department are remarkably complete and comfortable.

The third floor will contain the offices of the club, the rooms of the board of governors and committees, card rooms and some of the supply departments.

The next five floors will be devoted to garage purposes and the ninth will be arranged for the storage of parts, tires and other material for members and as a locker room. On the tenth, eleventh and twelfth floors are the machine shops of the club.

Out of a total available space of 187,159 square feet, 130,070 square feet are devoted to garage purposes, affording accommodation for more than 600 cars. The garage is open and available night and day and is equipped with modern devices of all sorts to facilitate the handling of motors. The club long ago decided to operate its garage strictly for the benefit of its members and "no commission" is the cardinal rule. Full lines of parts and accessories and the most advanced apparatus for repair work are included among the factors that have made this feature of the club favorably known throughout the world.

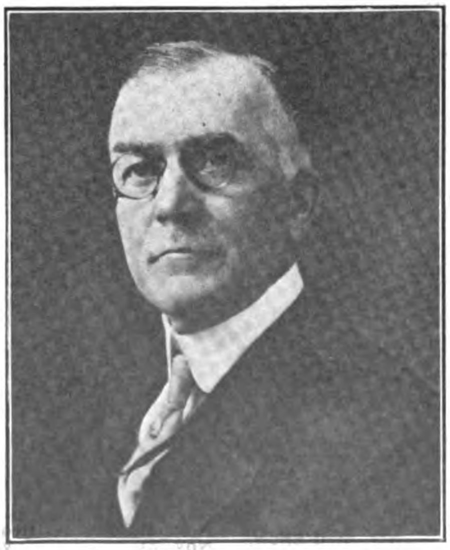
The membership of the club at the time of the retirement of President Gary was 2,055, divided into four classes, nearly 1,600 of which are active members. Since that time the growth has been normal and the total figures now are not far from 2,200. The new building will cost the club about $550,000. Needless to say the club is in flourishing condition financially.

As far as the sporting situation of the present is concerned, the Automobile Club of America is best known as the donor of the Grand Prize Cup, the second contest for which will take place October 15 on the Long Island Motor Parkway. The cup is of gold and is valued at $5,000. The club is not conducting the details of the contest.

In addition to the automobile, the club takes an official interest in aviation and motor boating.

The work of this organization is conducted on mechanical principles. The charter provides that the bulk of the detail work shall be done by committees and the formation of these committees has been a point of pride ever since the inauguration of the club as a forceful entry. The following compose the various committees of the Automobile Club of America:

Charles E. Forsdick, Secretary



Finis E. Marshall, Treasurer

Schuyler Skaats Wheeler, Cons'g Eng'r

Board of Governors—Henry Sanderson, president; Robert Lee Morrell, second vice-president; Edward Shearson, third vice-president; Finis E. Marshall, treasurer. Class I (term of office expires first Tuesday in April, 1911)—Frederick D. Underwood, Waldron Williams, William Pierson Hamilton. Class II (term of office expires first Tuesday in April, 1912)—Schuyler Skaats Wheeler, Colgate Hoyt, Alfred Ely. Class III (term of office expires first Tuesday in April, 1913)—John Jacob Astor, George F. Chamberlain, George Moore Smith. Class IV (term of office expires first Tuesday in April, 1914)—Dave H. Morris, Albert R. Shattuck, E. H. Gary.

Standing Committees—*Executive Committee*—Colgate Hoyt, *Chairman;* Robert Lee Morrell, Dave H. Morris.

Law and Ordinance Committee.—Wm. H. Page, *Chairman;* J. Dyneley Prince, Philip T. Dodge, Alfred Ely, John C. Brackenridge.

Good Roads Committee—A. R. Shattuck, *Chairman;* John Jacob Astor, Wm. G. McAdoo, Frederick D. Underwood.

Committee on Foreign Relations—Dave H. Morris, *Chairman;* A. C. Bostwick, Cortlandt Field Bishop, George Heath, J. Howard Johnston, Wm. S. Hogan, James A. Blair, Jr., W. W. Miller.

Contest Committee—Robert Lee Morrell, *Chairman;* E. R. Hollander, Henry H. Law, A. H. Whiting, Samuel B. Stevens, H. C. Pearson, Massachusetts Automobile Club.

Technical Committee—Alden L. McMurtry, *Chairman;* A. H. Whiting, A. L. Riker, Hiram Percy Maxim, M. A. Neeland, Alex. Churchward.

Bureau of Tours Committee—Colgate Hoyt, *Chairman;* Robert Lee Morrell, Dave H. Morris, George F. Chamberlain.

Committee on City Streets—Thomas Dimond, *Chairman;* M. M. Belding, Jr., Bryan L. Kennelly.

Committee on Public Safety—Winthrop L. Scarritt, *Chairman;* Henry Sanderson, Dave H. Morris, Colgate Hoyt, A. R. Shattuck, E. H. Gary.

Library Committee—J. E. Roosevelt, *Chairman;* G. Stanton Floyd-Jones, Henry R. Taylor.

Entertainment Committee—George D. Barron, *Chairman;* Emerson Brooks, H. L. Crawford.

Auditing Committee—Edgar L. Marston, *Chairman;* John I. Waterbury, Wm. M. Barrett.

Building Committee—Henry Sanderson, *Chairman;* Robert Lee Morrell, Dave H. Morris, Colgate Hoyt, J. Horace Harding.

Committee on Club Journal—George F. Chamberlain, *Chairman;* Robert Lee Morrell, W. W. Kelchner.

Membership Committee—Edward Shearson, *Chairman;* Lewis B. Brown, *Vice-Chairman;* Finis E. Marshall, Frederick D. Underwood, A. J. Hemphill, Ogden H. Hammond, J. C. Brady.

Motor Boat Committee—Henry Sanderson, *Chairman;* Ex-officio James A. Blair, Jr., George F. Baker, Jr., Henry H. Melville, Henry R. Sutphen (Motor Boat Club of America); Edgar Park, R. C. Seymour (Larchmont Yacht Club).

Aviation Committee—Cortlandt Field Bishop, *Chairman;* Dave H. Morris, Robert Lee Morrell, Colgate Hoyt, (Chas. Jerome Edwards, Samuel H. Valentine, A. Holland Forbes, J. C. McCoy, Aero Club of America).

Club counsel, Carter, Ledyard & Milburn, 54 Wall street, New York City; club attorney, W. W. Niles, 11 Wall street, New York City; club auditors, Haskins & Sells, certified public accountants, 30 Broad street, New York City.

Worcester Club Goes Up in Smoke

Worcester, Mass., Sept. 26—The ten rooms of the Worcester Automobile Club in the Chase Building, 44 Front street, considered the finest clubrooms in New England, were completely destroyed by fire early Thursday morning, at an estimated loss to the club and building owners of $175,000.

The fire, which started in the office of the club shortly before 5 o'clock from a defective wire, cigar or cigarette, destroyed the entire seventh floor of the building as well as the one below it. Five firemen were injured.

The automobile club is loser by about $35,000, of which about two-thirds was covered by insurance. The club's principal loss consisted of furniture and trophies.

President Daniel F. Gay has called a meeting of the board of governors for Tuesday night to be held in the rooms of the old Hancock Club at Lincoln square, and it is stated by some of the board that at this meeting a proposition to take over the Hancock clubhouse will be put up to the members of the Worcester Automobile Club, as well as those of the Hancock Club.

Correction

In The Automobile of September 8th these appeared a tabulation containing the specifications for the 1911 Marmon cars. In this table the price of the Marmon "Thirty-two" was given as $2,650 instead of $2,750. In this connection it may be noted that the wheelbase of this automobile is not 116 inches long, but 120 inches, as was emphasized on page 410 of the issue mentioned.

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL CLIMBS, ETC.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

EVERY man has his limitation, according to the statement made the other day by a well-known man who is making money in the automobile business. This authority for the "doctrine of limitation" seems quite positive about it, and he questions the accuracy of those who hold to the contrary.

* * *

WITH great frequency the Editor of THE AUTOMOBILE is addressed by young men who are attracted by the glamour of the automobile art, and they seek advice; they want to be told how to become a factor in a great and growing art.

* * *

FOR the young man who is absolutely honest, a worker, and who admits of no limitation, nothing can be easier than to enter the automobile business and take success away from the man who preaches the doctrine of limitation.

* * *

THAT the coming of the automobile has brought temporary success to many men, some of whom are of limited ability, is self-evident; even those who are willing to confess that man is limited in his ability are among those who gathered in a part of the harvest.

* * *

LOOKING for success in the automobile business today is like making a vain search for a needle in a haystack unless the searcher is honest, sincere, frank, fearless, and a worker. Does the candidate need a university education and the bolstering force of friends?

* * *

IT would be like trying to bolster up the claim of a "fallen angel" for a box seat in Paradise; the real workers would get in the way and the bolstered one would pine away in despair or slide back into the brine.

* * *

THOSE who desire to enter the automobile business and are glowing with ambition as they think, if they are merely animated with a desire to be rewarded for being on Earth, will find that the "ambition" that they are astride of is selling below par.

* * *

LET there be no mistake; the young man who desires to make a success does not even have to enter the automobile business; he will find what he wants in the way of raw material within himself. But if he is so constituted the automobile business needs him—needs him badly.

* * *

WHILE there is no limitation if the man so wills it, the fact remains that there are some serious handicaps; the man who "rests on his hard-earned laurels" is dead for the time being. Getting into a groove is like falling into a grave, only it is longer.

* * *

MOST young men, after they are afforded an opportunity to work, gather skill, just a little skill, complete some trifling undertaking, perhaps with some credit, and then what?

* * *

THEY find themselves in a sad predicament; the emolument that looked so good to them in the beginning ceases to patch out; the hats they wear rapidly shrink; in other words, the cost of a new chapeau large enough to fit a "swelled head" cannot be purchased out of a modest income.

* * *

THE work they so faithfully promised to perform is neglected; it is not fitting work for them; they want a better task to perform; the fact that some other man is doing the work more efficiently does not appeal—what can reach the center of reasoning of a man who is troubled with a dose of "swelled head"?

* * *

BUT what is a swelled head as compared with "exclusiveness"? What chance is there for the man who refuses to do anything but the particular work which attracts his discriminating (?) notice?

* * *

LEAKING is a bad habit for a ship to acquire; it is even worse in a man. Most men leak words; they talk too much; what they say will not stay said; they do not seem to understand that wisdom is as silent as a Sphinx.

* * *

RUTHLESSNESS is not an asset; the high disregard of the rights of others is the main disorder of the burglar and the cut-throat—why be ruthless? Success is neither defined nor measured by the accumulation of wealth that is not fairly acquired. The great chariot "Success" is of such large seating capacity that there is room aboard for all who are worthy.

OPPOSITION is the greatest braking mechanism that can be employed to pull down the ruthless; it will still the wheels of progress of the cruel and the greedy; it is the instrument of precision of the man who has to defend himself against the attack of the ruthless.

* * *

STRANGE as it may seem, the man who cannot "team" well with his confreres invariably gains the opposition of the most capable of them; the weaklings among them are not to be feared; it is the fellow that can do things, the man that knows that he can, who will put on the brakes if the ruthless and the greedy try to practice their religion in the camp that will have none of it.

* * *

CLIMBING up the ladder of ambition is a "boot-strap" proposition to the man who wants to thrust other men down; a real fighting, red-blooded man declines to make way; he puts up a fight; it is the fight of the man who has a principle in his keeping against the man who would not know principle if it met him coming down the road.

* * *

SHEER ability is capable of paying the interest at six per cent. on $1,000,000,000, with plenty of time left in which to court the nicest girl for miles around, marry the best woman in the world, play tag with the youngsters, be a friend to the man who may be in need of one, and offer a little encouragement to the unfortunate—if there are other duties to perform, sheer ability may be depended upon to find a way to accomplish them.

* * *

CRINGING is not teaming; it is not necessary to cringe; the companion or even the employer who wants a cringer should find them so scarce that they would come high. Should there be any for hire they are bad investments; the cringer has neither time nor capacity for becoming proficient in anything else.

* * *

LEANING backwards, trying to be honest, is the most dishonest practice that a living man can acquire; it is a clean case of dishonest honesty, if such it may be called.

* * *

SLANDERING is taught in the primary school of the blackmailer. Slander emanates from the unrestrained tongue of the irresponsible nondescript; he abides in low places, and a blight is put upon every undertaking that knows his way; nor does it matter whether or not it is in a plant for the making of automobiles or even on a newspaper.

* * *

THE automobile industry is in need of the clean and the industrious; it is in need of the man who is capable of shunning work long enough to take rest, refreshments and do a man's social duty—it is work, and more work, that has to be done; welcome is the man who will perform the tasks that await his coming!

* * *

WHAT fields of endeavor are open—automobile zones of activity—to the man who will work! There is scarcely a locked door in the whole industry. True, there are able men now holding sway behind many doors. Equally true, they are not the kind of men that are likely to stay down. When they work up, mind you, others must take their places.

* * *

TO the man who has a penchant for literary endeavor, the man who has an engineering bent and the ability to describe things as they are—not as some persons would like to have them distorted—there is a large field. Every maker of automobiles is in need of men who can take hold of the catalogue work, advertising, descriptive matter, etc.

* * *

TO the young engineer there is the drawing office; the place where the equipment is crystallized—what a splendid opportunity for a young man of working proclivities and a capacity for advancing!

* * *

TOOL-ROOM practice is now so important that a good automobile cannot be made without utilizing the services of a considerable number of tool-makers—this is a great field; it is no place for the man who has no capacity for thinking and for work.

* * *

SHOP ACCOUNTING is now regarded as of the greatest importance; it is necessary to keep track of the cost of everything without impeding the work, but the cost of the output must be determined the day it is finished—this takes brains and work.

* * *

ROUTING the work; keeping the men at the tools supplied with work; maintaining a brisk circulation; making sure that none of the work in progress will languish; nothing shall be side-tracked; just the place for intelligence of the class which wears no bells that handicap.

* * *

ELIMINATING complications in automobiles, reducing the total number of parts from perhaps 2500 to say 2000, represents an occupation that would bring vast returns to the workman who will give the matter sufficient attention, if he will be able to say when his task is completed that none of the eliminated parts will be missed when the automobile is put into service.

* * *

JUST sweeping the floor, and doing the other chores that would naturally fall to the lot of the man who is willing to work, paves the way from the lowest grade of position to the presidency of the largest company in the land. The sole requirement is to sweep the floor as perfectly as possible, being careful to collect the débris that generally hides behind half-open doors, but there is no objection to keeping the weather eye open with a view to doing other tasks if they happen along.

* * *

BEING a good salesman is something to consider, but in order to excel in this work, it is necessary to know nearly as much about the merchandise to be disposed of as the man who is responsible for its fabrication. Selling points, as they are generally perpetrated by a salesman, are plain, ordinary falsehoods projected from the tongue of the man who undertakes to paint a cabbage so that it will look like a rose—it is the truth that carries conviction.

Measuring the Wind for Aviators

METHODS USED AT ONE MEET FOR TELLING THE EXACT CONDITION OF AIR CURRENTS

TO allow of the greatest number of flights to take place at an aviation meet such as that to be held at Belmont Park, New York, in October, the first requirement is ability on the part of the aviators to tell, by some means in which they have confidence, the velocity and nature of the wind, not only near the earth, but also at various heights. A system announcing the velocity and steadiness of the air currents at 30, 100 and 200 feet above the ground, to say nothing of the services which might be rendered by means of an observation station located in a captive balloon, is recognized to be one of the crying wants for exhibitions, so long as the stability and equilibrium of aeroplanes are properties sought rather than materialized. The spectators who have paid admission, and therefore the box office as well, are interested in having all those intervals utilized for entertainment which can be utilized, and on the days when the velocity or character of the atmospheric currents changes considerably from hour to hour, a system of public announcement, such as by the sounding of gongs in conjunction with blackboard readings, not only keeps the spectators good natured, but also sets aside the doubts which might prevent the aviators from doing their best. Moreover, a record of the weather conditions, expressed in facts and figures and obtained by measurements, serves to facilitate comparisons between one performance and another.

Little has been done as yet to perfect the weather observations at aviation meets or any system for announcing and recording them. A beginning was made, however, at the meet which took place at Lyon, France, in the fore part of the Summer, and the arrangements made on that occasion may be described and, in default of more complete ones, may serve to illustrate some of the requirements.

Professor André, of the observatory at Lyon to whom the committee appointed to take charge of the matter first applied, took care to impress upon the members the need of minute precautions if illusory results should be avoided in the measurement of something so variable and unstable as the wind. It was out of question to just put up a few anemometers, such as may be bought in the open market, here and there along the level of the ground, as had been done at previous aviation meets. To raise a platform 50 feet above the field and install a station thereon would have entailed considerable expense. This difficulty was met in the following manner: A mast was raised 17 meters high and braced against the stand of the timers in the middle of the field. Being removed from all obstacles and higher than any, an apparatus at the top of this mast would not be in the path of eddies. By means of rails on the side of the mast and a pulley arrangement a wooden frame could be hoisted to the top and very readily taken down to the ground for inspection and adjustment. The choice of a suitable instrument was the next care. Anemometers used in the observatories are nearly all of the Robinson type, that is, they consist of four semi-spheres made of sheet metal mounted, with the circular edge placed vertically, upon the ends of four arms turning in a horizontal plane. The inertia of this instrument is too great for measuring feeble winds unless the semi-spheres are made quite large; and then the device, in case of being actuated by a strong gust of short duration, continues to revolve for some time after the cause has ceased. It serves very well to measure averages, but not the frequency or suddenness of gusts, and these are after all the features of greatest interest to aviators. Instead, there was adopted a very light device with inclined blades turning in a plane perpendicular upon the direction of the wind. Most devices of this type while quite sensitive are provided with a dial affording a direct reading of the velocity of the wind and they must constantly be turned by hand so as to face the wind. To obviate these two shortcomings the device was combined with a weather vane, which would automatically correct its position to the wind, and the dial mechanism was replaced with a simple gear which closed an electrical circuit once for each turn of a light spur-wheel meshing with a small pinion on the axis of the device. It was then easy to measure the velocity of the wind as well as its regularity by the dots produced by the electrical contacts on a roll of paper unwound by clockwork at the foot of the mast.

As the anemometer device employed was set in motion as soon as the velocity of the wind reached 10 centimeters per second, it was necessary to employ a weather vane of equal sensitiveness. It was constructed of a light wooden frame covered with aeroplane cloth so as to form a dihedral angle of about 5 degrees, and this shape was chosen so as to avoid the oscillations which would certainly result if a single plane were placed in the little eddies which would be formed directly behind the vertical shaft of the weather vane. These surfaces measured 0.4 by 0.4 meter and were supported by a wooden arm measuring 0.7 meter, in such manner that the distance from the center of gravity of the planes to the shaft was not less than 0.5 meter. The weight of this weather vane apparatus was exactly balanced by a piece of lead carried on a stem extending on the other side of the vertical shaft. The balancing was done with great care with a view to having the weather vane function with correctness even if the mast were not exactly perpendicular—and some flexion of the mast was to be expected, considering its dimensions and its rather weak support. The shaft of the weather vane was mounted in ball-bearings, and under these conditions the apparatus placed itself perfectly in a current of air as slow at one-tenth to one-twentieth of a meter per second, even when its shaft stood at an angle of 30 degrees with a plumb line. Finally, the anemometer device was attached by means of a little clamp to the top of the shaft of the weather vane.

In order to get readings of the direction of the wind, rather than providing the vane with an index hand displacing itself over a fixed rose it was preferred to use a fixed index and to mark the rose on an inverted truncated cone secured to the weather vane. In this manner it was possible to read the direction, even from the foot of the mast, with considerable accuracy and without displacing one's self in order to face the index.

The calibration of the apparatus took place in a large closed hall. It was moved against the air a given distance, and a large number of tests made at different speeds resulted in establishing the figure of 3.20 meters as practically a constant for the distance covered between two contacts. The transmission of current took place at one end through the metallic mass of the device and through an insulated bronze ring at the lower end, against which there leaned lightly a small fixed brush also insulated. The closing of the circuit thus obtained was utilized to ring a bell placed in the interior of the station and connected to the instrument by a flexible wire. By measuring with a stop watch the time elapsed between two consecutive rings of the bell the time was obtained in which the wind covered 3.20 meters, and the velocity in meters per second was read off by means of a corresponding schedule prepared in advance. In reality the elapsed time was not measured between two consecutive bell signals, but between ten such, corresponding to a distance of 32 meters.

This acoustic method of signaling was found very convenient, as the bell could be heard at a distance of several meters on the outside of the station, so that every variation in the speed of the wind was noted by every person in the vicinity. In addition, every signal was recorded, as above mentioned, by a chronographic register, so as to check all readings.

The station was also equipped with barometers, thermometers and hygrometers, all self-registering, which rendered it possible to record with considerable accuracy all the meteorological conditions under which flights were made, and twice each day telephonic communications were received from the observatory announcing whatever changes in the weather appeared to be approaching.

Events Among Aviators

HISTORICAL associations surround with glamor the feat of Georges Chavez, who crossed the Alps in a Blériot monoplane on Sept. 23. The Italian Aviation Society had offered a prize of $20,000 for flying from Brigue, Switzerland, to Milan, Italy, by way of the Simplon Pass, whose altitude at the lowest point is about 7,000 feet, but unfortunately the young aviator after accomplishing forty miles of flight at the high altitude and braving fierce currents rising from the steep Italian side of the mountains, undertook to descend by gliding to Domodossola, an aeronautic station located on the plain on the way to Milano. When arrived within fifteen feet of the ground he lost control of the machine, whether this was due to a sudden upward swerve at high speed or to a gust of wind, and the machine turned a somersault and came down on top on Chavez, breaking both his legs and inflicting contusions on face and shoulders. As his recovery at first seemed probable, a committee of the Italian Aviation Society began to raise a $10,000 consolation prize for him, while a penny subscription was started for the purpose of erecting a monument at the spot where he landed, to commemorate the first human flight across the mountains which Hannibal, the Visigoths and Napoleon had crossed with their armies only at great peril and with much loss of life. But on Sept. 27 Chavez succumbed to his injuries.

On Sept. 19 Chavez made his first attempt, but found the tops of the Simplon enveloped in clouds and returned safely to Brigue. Thereafter he explored the mountain daily by automobile, and on the day of the event he came rushing down from Simplon Kulm, reached Brigue at 1:30 p. m., took the monoplane out of its shed, mounted it and had it started, and at 1:40 the spectators caught the last glimpse of him disappearing over the hazy outlines of the mountain peaks. The telephone announced that he had passed the Kulm at a height of 450 feet. Another message a few minutes later said he had passed Gondo. But the bell rang again, and now he had fallen at Domodossola. Just before he started, Henry Weymann, an American aviator favorably noticed for his gallant work in the Eastern Circuit contest in France and for his subsequent attempt at winning the large Michelin prize for reaching the Puy de Dôme with a passenger in direct flight from Paris, had returned from a vain attempt at the same coveted feat, having found that his Farman biplane was unable to reach the altitude necessary for crossing the mountains. Chavez was born in Paris 23 years ago and gained fame among aviators in the beginning of this month by beating Morane's altitude record. Rising from Issy-les-Moulinaux he reached the height of 8,792 feet in 41 minutes.

Much discussion has been stirred up among aviators with regard to the reasons for the accident which befell Chavez. He came down in gliding flight with the motor idle, and it is the opinion of many monoplane operators that this method of descending is dangerous because, in case of a sudden cross current in the atmosphere which disturbs the equilibrium, the aviator is deprived of the motor power as a means for regaining his balance quickly by spurting forward.

Hubert Latham and Louis Bréguet have been nominated for decoration with the cross of the Legion of Honor for meritorious work in connection with French military aeroplanes.

W. K. Vanderbilt, Jr., has ordered a Blériot monoplane provided with a 60-horsepower Gnome motor and an auxiliary motor of smaller power to be used either in combination with the main motor or as auxiliary when the latter is incapacitated. It is said to be ready for delivery and capable of fantastic speed.

On Sept. 16 Aubrun flew a Blériot machine 186.3 miles in 3 hours 33 minutes and 7 seconds, making an average speed of about 55 miles per hour, and breaking the record for combined speed and distance.

Two aviators, Loridan and Mahieu, attempted on Sept. 26 to make the flight from Paris to Brussels, for which the city of Paris and the Aero Club of France had offered prizes totaling $35,000, provided the flight was made with a passenger and finished on the day mentioned. Loridan reached St. Quentin, 81 miles from Paris and about one-half of the required distance, and fell from a considerable height, injuring himself and the passenger. Mahieu reached nearly as far, but fell from a height of 60 feet near Lafère. Both he and his passenger escaped injury.

The National Council of the Aero Club of America has sanctioned the conditions for a race from Chicago to New York, as outlined by the New York *Times* and the Chicago *Evening Post,* which jointly offer a prize of $25,000 for the winner. The race is to start from the Hawthorne race track, near Chicago, on October 8, if the weather permits, and must be finished in New York City on or before October 15. At least three competitors must start, and the start may be postponed from day to day on account of bad weather, which provision leaves a considerable element of uncertainty, if one or two elect to start, considering the weather sufficiently favorable, while the third competitor holds back and possibly does not start at all. Between the start and the finish the competitors may descend and rest and repair as they please. A large number of competitors have been announced from time to time. An additional prize of $5,000 has been offered by Clifford B. Harmon, a well-known amateur aviator of New York City. The fliers are supposed to follow the old automobile route via South Bend, Toledo, Cleveland, Buffalo, Rochester, Syracuse, Albany.

At Belmont Park, New York, preparations are being pushed for the great international aviation meet to be held October 22 to 30. Sheds for housing the machines of the contestants are now being erected and when finished will be at disposal for all aviators officially entered in the meet, and they may thereafter begin practicing flying when they choose. J. C. McCoy, chairman of the committee on aviation, announces the following entries: Leblanc (Blériot), Latham and Thomas (Antoinette), Lesseps, Morane and Aubrun (Blériot) and Simon, all from France; Graham-White, Radley and Ogilvie from England; Moissant and Weymann, American aviators flying French machines, and the American aviators Charles K. Hamilton, Walter Brookins, Ralph Johnstone, Thomas S. Baldwin and Tod Shriver. The ground at Belmont Park has been cleared of all obstructions and presents a clear field, with the exception of the pylons, which are slender towers serving to mark the course of contests. What was the old betting ring underneath the grand stand has been transformed into an exhibition hall where flying machines, automobiles and other things connected with outdoor sports will be exhibited, and arrangements are made for a restaurant service which will render a whole-day stay at the grounds practicable.

The Muffler on Aviation Motors

A good muffler absorbs only about 8 per cent. of the power developed in a single-cylinder motor. While the loss is usually somewhat larger in a multi-cylinder motor, it is on the other hand reduced about 80 per cent. before it reaches the propeller, owing to the inefficiency of the latter. The loss in propulsive power in applying a muffler to the motor of an aeroplane engine would therefore at the present stage of propeller efficiency not exceed 2 per cent., and the return in comfort as well as in ability to hear other motor sounds would compensate for this small loss. The additional weight of a muffler for a 50-horsepower motor is estimated at 10 to 15 pounds, including the exhaust tubing required for reaching it.

Auto Show of 1911

MOST COMPLETE LINE OF CARS EVER EXHIBITED UNDER AUSPICES OF A. L. A. M. WILL GRACE MADISON SQUARE GARDEN IN JANUARY

ACCORDING to all indications, the coming Eleventh National Automobile Show, which will be held at Madison Square Garden from January 7 to 21, 1911, will set a new mark in that important branch of motor activity. While it is still three months before the doors will be thrown open to the public, all space has been assigned for the first section of the show as shown in the accompanying series of illustrations.

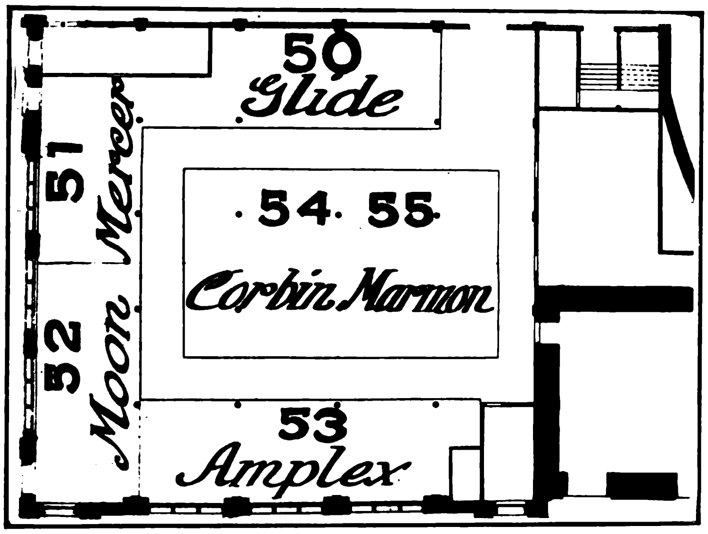

Diagram showing disposition of space in Exhibition Hall

The exhibition of 1911 is divided into two parts. The first will be entirely devoted to the display of passenger or pleasure cars and will last until January 14. The commercial or freight vehicles, electrics and motorcycles will be on show beginning January 16 and will remain until the night of January 21. The parts and accessories display will run through both weeks of the exhibition.

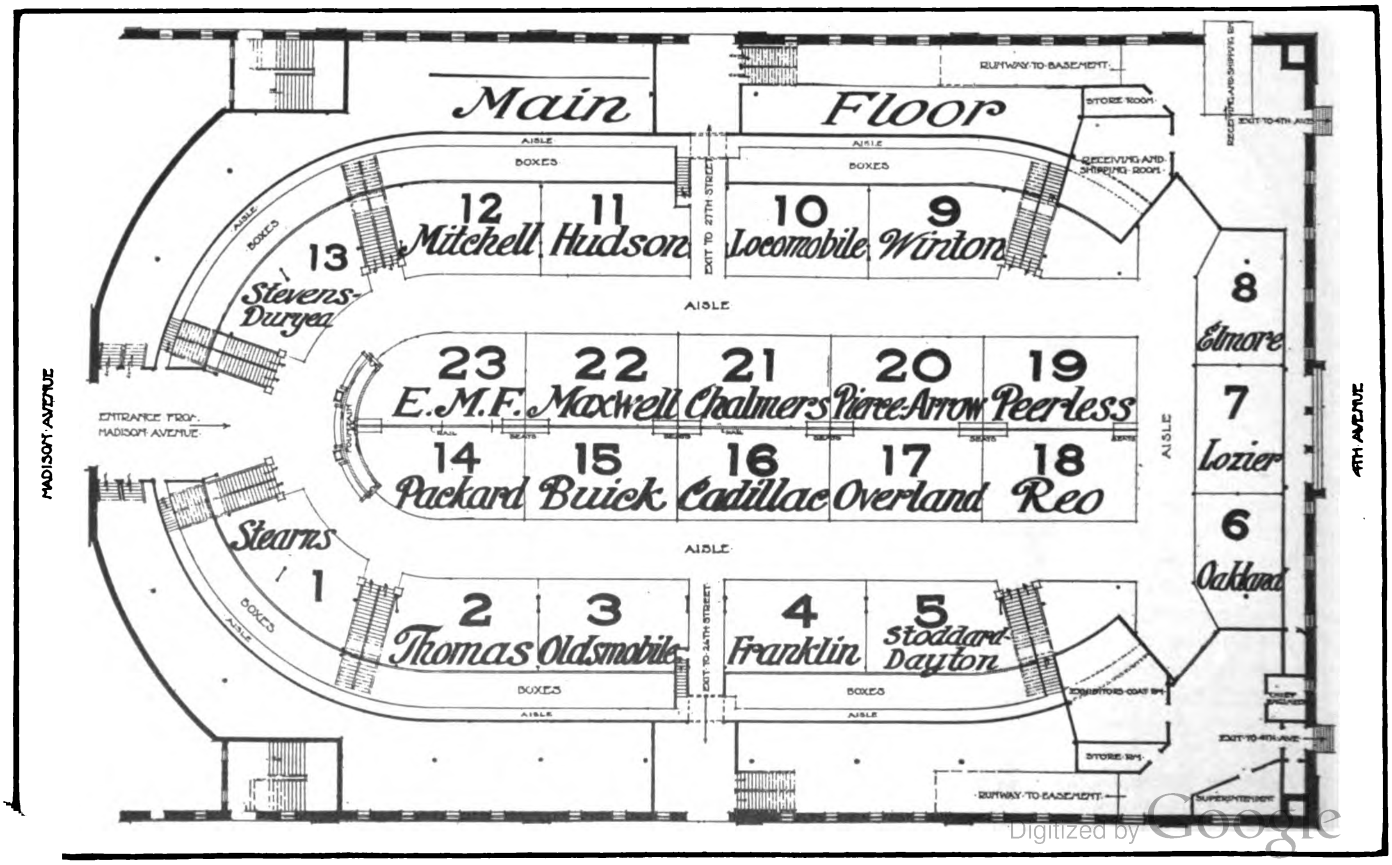
The main floor of the garden will contain twenty-three exhibits, thirteen of which will be strung around the outer edge of the big exhibition room. In the center there will be ten exhibits, while those in the big circle will be divided from the center block by wide aisles. Around the outside of the big circle the boxes will be arranged and still farther out from the center an aisle will afford easy passage about the hall.

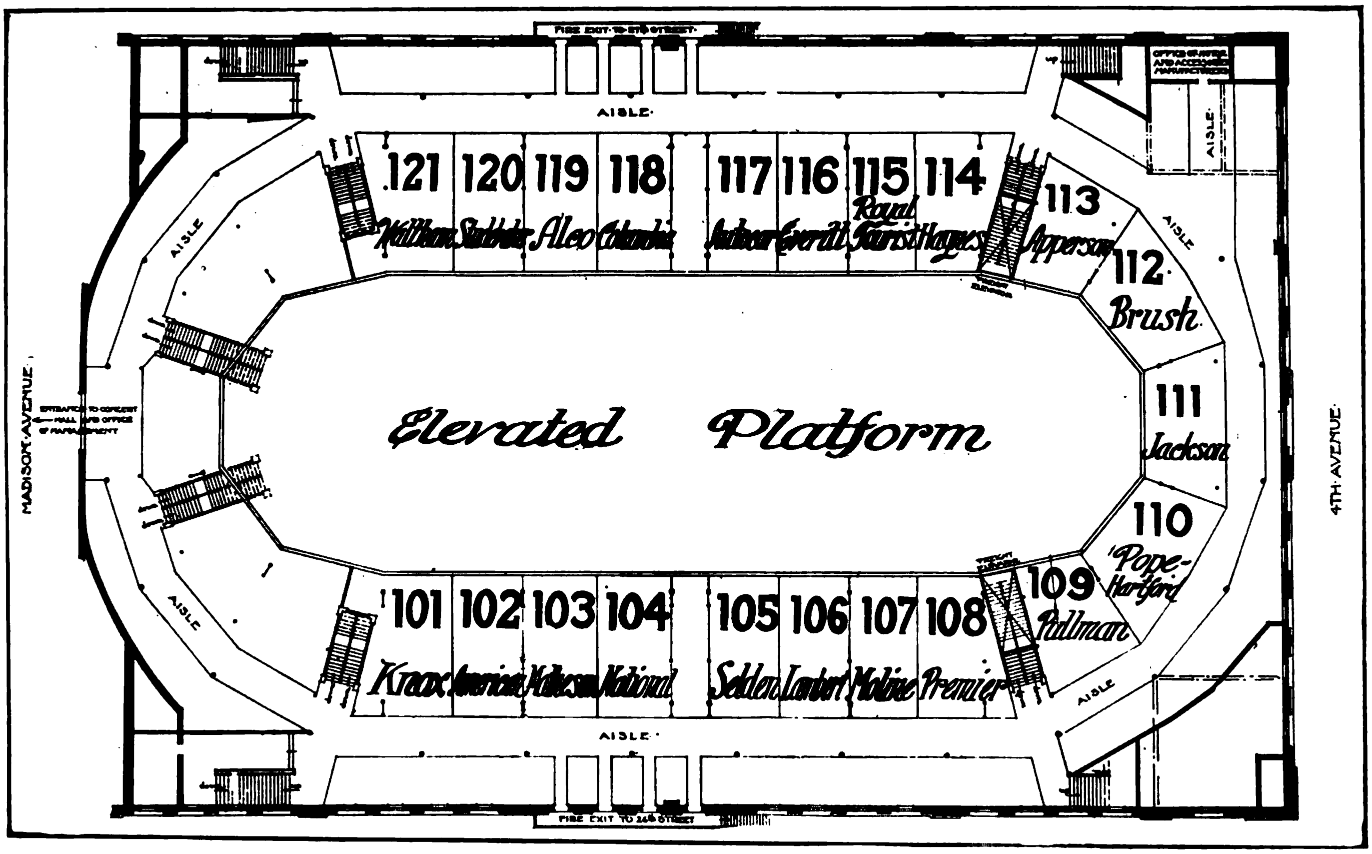
On the elevated platform twenty car exhibits will be quartered in a magnet-shaped formation which will be encircled by a wide aisle to give opportunity for close inspection by the public.

Exhibition Hall will contain six car exhibits and in the balcony there will be twenty more in the same formation as that followed on the elevated platform. Thus sixty-nine exhibits by as many distinct automobile companies will be shown during the first seven days of the national show. Nothing like as complete a line of cars made by licensees under the Selden Patent has ever been shown, because during the past year the membership in the Association of Licensed Automobile Manufacturers has increased materially and several newcomers will exhibit their product.

The foreign cars licensed under the patent will be well represented and the domestic field will be about as complete as it is possible to make it.

In order to provide space in the garden under this plan, a number of radical changes will be required in the main floor. Preparations for these changes will be made with a wealth of detail so that when the time comes for the alterations the girders and supports that will be used in changing the interior can be moved in and bolted together in the shortest possible time.



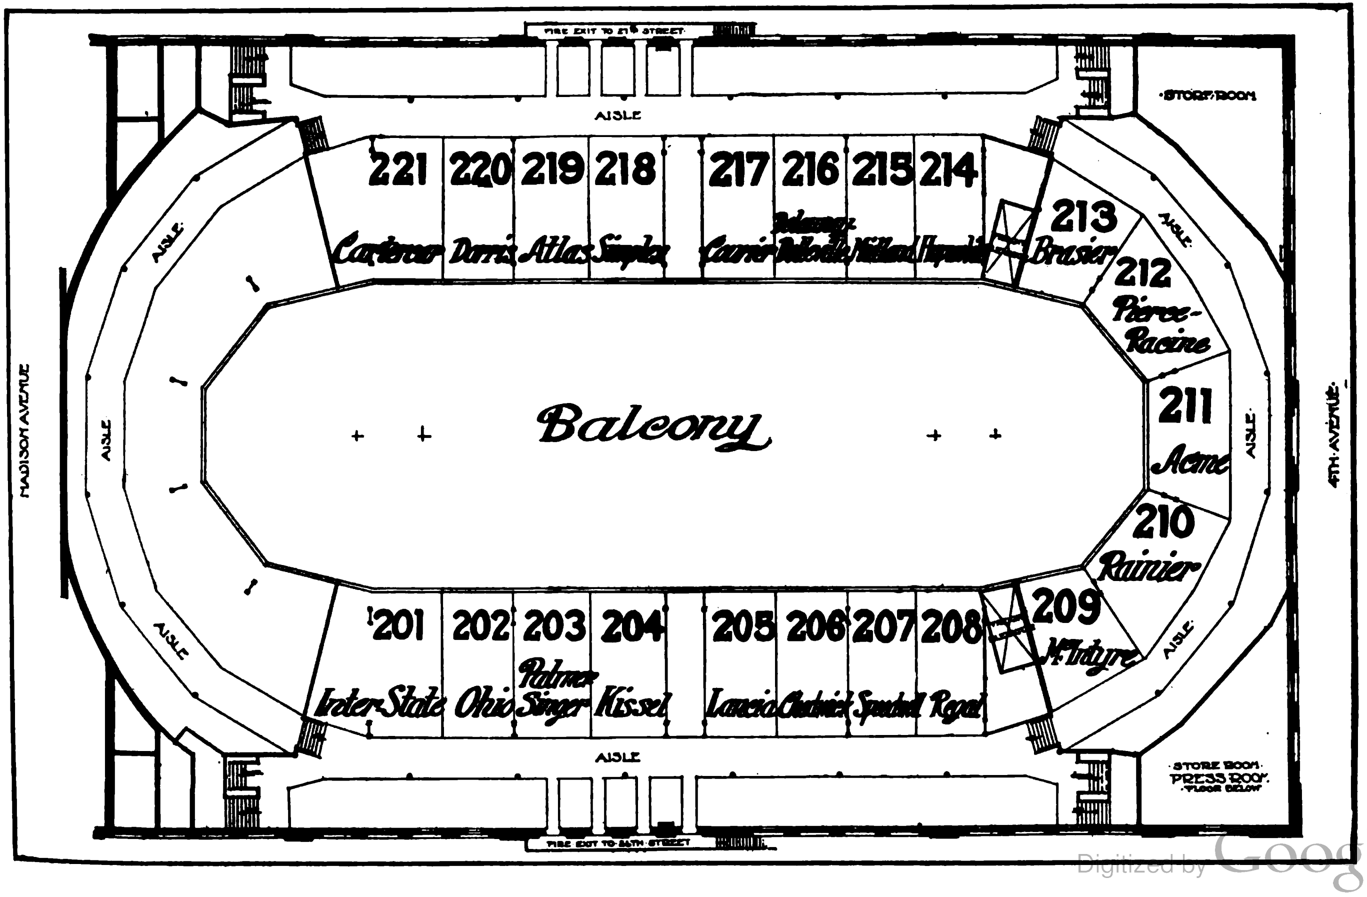


The decorative scheme has been worked out and according to announcement it will be more artistically beautiful than ever before.

Public interest in the National Automobile Show has always been intense and this year, with the growth and development of the industry, it is expected that the attendance will be larger than it was at the previous high-water mark. The musical programs, which are now being arranged, will be very complete and all indications point to the highest class of entertainment of that kind.

Society will be represented to a larger extent, this being foreshadowed by the early reservations.

The committee in charge of the enterprise consists of the following: Chairman, Colonel George Pope; Charles Clifton, President of the A. L. A. M.; Alfred Reeves, General Manager of that association, and Merle L. Downs.



Defend Auto Industry

CHIEFTAINS OF THE BUSINESS TELL WHY THE MOTOR CAR WILL REMAIN A PERMANENT FACTOR IN CIVILIZATION AND MODERN DEVELOPMENT

THE recent attack of banking interests upon the automobile industry has led to expressions of opinion on the permanency of the automobile by numerous men prominent in the business. In a symposium compiled by *American Industries* the following statements will appear in October:

"Probably the best answer to the charge of overproduction can be answered by pointing to the export trade. Had there been any real over-production, automobile manufacturers would have turned to the foreign market long before this."—F. B. Stearns, president The F. B. Stearns Company.

"The tendency to luxurious living, which has been attributed to the automobile, is no more the result of the motor car than is any of the other thousand and one things which contribute toward making life more luxurious than it was two or three decades ago."—H. H. Franklin, president Franklin Automobile Co.

"A great hullabaloo has been raised because the automobile is diverting trade from speculation, the purchase of jewelry, millinery and has taken money from saloons and resorts. In so doing, it is doing much to unite families, parents and children in their recreations and pleasures."—E. R. Thomas, E. R. Thomas Motor Co.

"With the big end of the business still untouched (that of building delivery wagons and trucks), it is safe to say that the industry is still in its infancy and has a future ahead of it too gigantic for any of us to even conceive."—R. H. Salmons, general manager Selden Motor Vehicle Co.

"Whatever volume of money has been expended in motor cars, represents money in motion. And that money in motion has kept busy the wheels of industry during and after the panic of 1907."—Alexander Winton, president The Winton Motor Carriage Co.

"We do not believe there is any over-production of high-class or high-grade cars."—L. W. Rinear, The White Co.

"There is no doubt but that in the near future the American motor car manufacturer will have to give liberal acceptance to that logical outlet channel in the foreign field."—N. I. Taylor, Regal Motor Car Co.

"From this period of transition will emerge, strong and capable, a coterie of immense, well-managed firms of manufacturers to enter upon the work of supplying the public with a product for which there will ever be an established demand."—Walter E. Flanders, E-M-F Co.

"Transportation is civilization. Time saved is money made."—Maxwell O. Parry, Parry Auto Co.

"The motor car has become as necessary to the farmer as his most valued farm machinery by putting him nearer his market and his friends."—George M. Dickson, National Motor Vehicle Co.

"It is no longer possible to sell an automobile simply because it is an automobile. The public has become educated to their use and value."—W. B. Roberson, Alpena Motor Car Co.

"The automobile is with us to stay, and neither the pessimistic banker with his four or five cars, nor the stock jobbers of Wall street, can prevent the increasing utilization of such an essential factor in civilization as the motor car has become."—R. W. Hutchinson, Jr., Pullman Motor Car Co.

"So long as the common people class the automobile as a luxury rather than a utility, just so long will the industry require tender nursing."—O. R. Hardwell, Sears, Roebuck & Co.

"The farmers who will be large consumers in future have the money to purchase with and they will certainly spend it as they choose."—G. A. Mathews, president Fuller Buggy Co.

"Competition there is and competition aplenty, but ruinous rivalry will not enter where so much is at stake."—H. A. Lozier, Lozier Motor Co.

"There is an outlet for all cars of merit in this country."—George C. Holtz, Badger Motor Car Co.

"The automobile has come to stay because it brings to a live people increased facilities for the transportation of both freight and passengers."—Charles H. Pope, Midland Motor Co.

"The country is not bankrupting itself in buying autos, but is demonstrating its progressiveness and prosperity."—D. M. Parry, Parry Auto Co.

"The commercial vehicle will be an indispensable proposition and will be of great benefit in all the larger cities."—W. W. Sterling, Elkhart Motor Car Co.

Field Day for KlineKar at Norristown Meet

PHILADELPHIA, Sept. 24—Six races, a couple of time trials and several motorcycle races constituted the card presented by the Norristown Automobile Club at the Narberth race course, near this city, to-day. Two stock car events under piston displacement classification were won by a KlineKar driven by C. C. Fairman and a third event by a Warren-Detroit. The KlineKar was opposed in both its races by two other KlineKars. The same KlineKar won the free-for-all handicap. The free-for-all at five miles was won by a Fiat and the program concluded with a freak "secret" time race at two miles, which was won by an Otto car. In the time trials at one and ten miles a Fiat made :49 1-5 and 8:31 1-5 respectively. As the automatic timing devices were out of order, it is unlikely that either mark will stand.

The summary:

One-mile time trial—

Car	Driver	Time
Fiat	De Palma	0:49 1-5
Five-mile race, 231 to 300 cubic inches—		
Warren-Detroit	Tom Berger	5:23 4-5
Otto Car	Geo. H. Jones	5:39 1-5
Five-mile race, stock chassis, 301 to 450 cubic inches—		
KlineKar	C. C. Fairman	5:58
KlineKar	W. D. Morton	5:28 1-5
KlineKar	James D. Kerr	5:34 1-5
Ten-mile time trial—		
Fiat	De Palma	8:31 1-5
Ten-mile race, stock chassis, 301 to 450 cubic inches—		
KlineKar	C. C. Fairman	10:44 2-5
KlineKar	W. D. Morton	10:44 3-5
KlineKar	James D. Kerr	10:45 1-5
Five-mile, free-for-all—		
Fiat	De Palma	4:57 2-5
Warren-Detroit	Tom Berger	5:03 2-5
Otto Car	W. J. McFarlane	5:06 2-5
Ten-mile, free for all, handicap		
KlineKar	C. C. Fairman	10:32 1-5
KlineKar	J. D. Kerr	10:32 2-5
Otto Car	W. J. McFarlane	10:33
Two-mile race under legal speed limit (secret time 6 minutes 30 seconds)—		
Otto Car	W. Kruse	6:08
Otto Car	W. J. McFarlane	6:06 1-5
KlineKar	C. C. Fairman	5:57 2-5

Salisbury Fire Prevents House Party

Owing to a visitation by fire on the night of September 21, which destroyed plant No. 2 of the Salisbury Wheel & Manufacturing Company, at Jamestown, N. Y., the annual house party of the company, which has come to be regarded as one of the features of the social side of the automobile trade, has been called off.

The building will be a total loss to the company, and arrangements have been so disordered by the occurrence that the recall of the invitations to the house party was necessary. The function was to have taken place the week of September 30.

Land of Motoring Promise

BY HENRY MacNAIR. GOOD ROADS AND NATURAL WONDERS IN THE OFTEN OVERLOOKED STATE OF MAINE. TIMELY SUGGESTIONS FOR OCTOBER TOUR

NOT alone to the explorative tourist who has wearied for the nonce of the furrowed telford and hummocky macadam which betoken the lanes of the rabidly strenuous, but to the seeker after recuperative delight in the restful haunts of nature does Maine's varied expanse of forest and lake make seductive appeal. Maine, the eastern outpost of the "States," with its lace-like fringe of coast, and its five thousand laughing streams which call up alluring visions of conquest with net and rod!

Since 1614, when Captain John Smith ranged the New England coast from the Penobscot to Cape Cod, countless thousands have journeyed to that romantic primeval land whose charm has oft been told in song and story. Mason and Gorges planted colonies on its jagged coast, then Massachusetts reached out a long arm and embraced that portion of "Ye Mayne Land" so-called to distinguish it from the many bordering islands. For a hundred and sixty-eight years it remained the District of Mayne, in turn devastated by torch and tomahawk, and rent with cannon and bayonet. At last came its days of peace, and the Pine Tree State has become the playground of the Nation, the rendezvous of the mighty Nimrod, the haunt of the mute inglorious Walton. But the motor car held back, and he who braved the mountain fastnesses of this *terra incognita* was a pioneer indeed. Few knew, and many need now to be told, that the State of Maine has more miles of excellent natural highways than any of its New England neighbors. Few indeed are there who can tell of Maine's fifteen hundred lakes, of her twenty-five hundred miles of coast, and fewer still of her five thousand miles of touring roads. The misconception of road conditions in this, the largest and in many respects the most interesting of our Eastern States, is due in part to the fact that the poorest of her highways are on the New Hampshire border; her gateways seem closed to the motorist. He ventures along the sandy banks of the Androscoggin, or the Saco, he returns and essays the rough and stony road which leads from ancient Kittery to Portland's promontory, and retires in disgust at what seems to portend a halting, limping journey through a wildnerness. But let him push on along the coast to Bangor, or ascend the peaceful Kennebec to Moosehead Lake, then no slight discomfort of the road will abate his enthusiasm for the glorious and ever-changing panorama which has been so prodigally laid out before him.

Rangeley Lakes and Poland Spring were formerly the *"Ultima Thule"* of the automobile tourist, but of late days the doughty motor chugs its way to northernmost Fort Kent, to Eastport and on through quaint old St. John with its reversible waterfall, or climbs the international range of hills and descends the beautiful valley of the Chaudiere to the walled and historic Quebec. These and many other delights are his who ventures far afield, though none need seek beyond the confines of the State for abundant enjoyment of wheeling over smooth and picturesque roads. One who has traveled from Bangor to Moosehead will always pleasurably recall the twenty-mile stretch along a ridge which the natives call a "hossack." How the dial-finger pointed continually at thirty or thirty-five or forty, with never a "Thank-you-marm" to disturb his gears, or his equipoise. And then the drive down the east side of the majestic Penobscot; who could ever forget it? Unless perhaps the memory of its manifold beauties was eclipsed by the subsequent trip along the coast near Rockland.

What more would you have in this list of good things which Dame Nature has provided for Maine's perennial feast to the eye and the soul? Poland Spring, for more than a century the resort of the aristocratic and wealthy, its beneficent waters known on both sides of the Atlantic, its quietly restful surroundings appealing to all but those inoculated with speed-mania. The chain of lakes known as Rangeley Lakes, but individually known as Mooselookmeguntic, Welokennabacook, Molechunkamonk and others, bountifully stocked with the finest of trout and bass; and nearby accommodation for the tourist in the finest of hotels, in a comfy log cabin or in a tent. Portland with its famous lighthouse, its unapproachable Casco Bay, its Longfellow houses, and its top-story dining rooms. Augusta with its Capitol and Blaine residence, overlooking the ice-yielding Kennebec. Belgrade Lakes the beautiful, meant only to drive dull care away. Auburn and Lewiston, the twin cities of the Androscoggin, busy in their making of cotton and woolen goods. Rockland and the stretch of unequaled coast, whose beauty can only be known to him who sees. Bangor on the Penobscot, standing at the doorway of the magnificent Aroostook country, a center for many charming tours on unexcelled gravel roads. Moosehead Lake, the source of the Kennebec, with its four hundred miles of shore line, its islands and hunting and fishing camps.

Then, too, are the vast forests of the North where abound the moose, the caribou and the deer, delimited by the majestic rivers St. John and St. Croix, with their many tributary streams and lakes. All this and more goes to make an ideal spot for the annual gratification of our wanderlust, where we may forget the dull grind of commerce and like Walt Whitman "invite our souls."

PRACTICABLE MOTOR TOURS IN EASTERN MAINE

[Reproduced by permission from the Official Automobile Blue Book. The numbers on the heavy lines refer to corresponding routes in the New England volume.]

H. H. Franklin Interviewed

PRESIDENT OF THE H. H. FRANKLIN MFG. CO. IN RESPONSE TO QUERIES BY "THE AUTOMOBILE" GIVES HIS VIEWS ON PRESENT SITUATION

A—What is the attitude of the banks?

A—The usual attitude—by that I mean that the bankers will look upon automobile propositions just the same as they would any other legitimate mercantile establishment. My experience with the banks has been that they are not unduly alarmed.

B—Is there much paper out?

B—While not fully informed I was surprised during a slight investigation that there was not apparently an abnormal amount of paper out.

C—Will the various makers of automobiles be able to meet the payments as they come due?

C—Answer to this question depends on what is meant by "various." Conservative, well-conducted concerns will certainly be able to meet their payments.

D—To what extent will the paper that is out be extended?

D—Not informed.

E—How are the accessory makers making out?

E—Not informed, but do know that indications are that these manufacturers have caught up with their orders, and are apparently in position where they can handle the requirements of the business.

F—What will be the automobile output for 1911?

F—Not to exceed one-third of 1910. There is reason to believe that the 1910 output as to number of automobiles will not be exceeded for many years.

G—Will the 1911 automobiles be high or low priced relative to the 1910 output?

G—Prices as fixed seem about the same. Trade conditions will undoubtedly affect some prices.

H—Will the present method of selling continue? If not, what are the probable changes that will be made?

H—No. Selling will be on the same basis as any legitimate business. A basis upon which it has been conducted up to the present time. A cash basis will also be done away with, and this phase of the situation should be given considerable attention by the manufacturers, for it is certainly more expensive to do business on a credit basis than on a cash basis.

I—Will the prosperous makers of automobiles, like the Franklin, get behind the weaker companies and keep them from going to the wall?

I—No. Not anything would be gained if they did.

J—Will there be a combination of interests more than is in sight at the present time?

J—Not informed; but not anything will be gained at this time by a combination.

K—Will the Knight type of motor be taken up in this country?

K—Very likely. The tendency, of course, in this country is to take up and look into anything that looks like a development.

L—Will the Franklin company do anything by way of adapting rotary valves?

L—Franklin engineers at this time do not see anything in the rotary valve.

M—What is the greatest extravagance in the automobile business, in other words, what points are there that can be manipulated that will lead to a lower cost of production?

M—The whole automobile business has been on an extravagant basis. The rapidity with which changes and improvements have been made has added very much to cost. The main thing that will lead to lower factory cost will be standardization, fewer changes, better organizations, special machinery, etc.

N—What is the exact reason for desiring to use large tires on automobiles? Please deliver exact data on this point.

N—Solely for economy and freedom from tire troubles. To best illustrate this point, I will say that the better class of cars carry the same tire equipment which is carried on the Franklin cars and use from three to four sets of tires to negotiate 10,000 miles, while our one set of tires average us the same distance. This statement is not made from any theoretical estimate but from actual facts substantiated by owners of the Franklin car from whom we have gained the information.

O—How is the second-hand car question to be handled?

O—On a strictly business basis.

Communications

Regarding the attitude of the underwriters in connection with gasoline trucks not being allowed on the docks of piers in New York City.—Many of the leading firms in New York are to a great extent bound up with the docks in view of the fact that a percentage of their goods are imported.

As you are well aware a properly constructed gasoline truck with a properly constructed gasoline tank is as immune from fire as an electric vehicle. In other countries, England to wit especially, the underwriters, insurance companies, etc., insist upon inspection of the gasoline tank and after approval no further question is raised about their going in and out of the docks and piers.

We would point out that New York possesses some of the finest docks in the world, far superior in construction and protection against fire to any others that have been the writer's lot to view. Around London there are still many wharfs and docks constructed solely of timber, and these would be more liable to catch fire than your superb New York wharfs. The English Board of Trade statistics have shown that during the last two years not one single case of fire has occurred through the entry of gasoline trucks on their premises. Considering that the handling of goods, due to the enormous imports and exports of London, are, we believe, very much greater than those of New York, and taking into consideration again the fact that New York piers have better protection against fire than the London ones, it beats us entirely to appreciate the underwriters' attitude.—W. A. Wood Automobile M'f'g Co., Julian A. Halford.

Should makers guarantee their car indefinitely?—It has occurred to me that the one thing that will build up the automobile situation is to get a value on second-hand cars. To-day a second-hand car has little or no value from a factory standpoint, that is, I mean to say that a new car is sold with a guarantee against defects and all faulty material so long as it remains in the hands of the original buyer, but the moment it has been sold and it is in a second man's hands the factory disclaims any responsibility whatever.

Now, the factory that will come out and guarantee their cars so far as to replace any defective material free of charge at any time, in other words, guarantee their cars for life, will immediately place a value on the second-hand car which will materially affect those who have been attempting to borrow money from the banks on automobiles. That is to say, the banker will see some kind of value in an automobile. To-day the banker sees no value in an automobile and most bankers that I have had the pleasure of talking with during the last month consider an automobile a liability rather than an asset of its owner.—A. R. Mosler & Co., C. C. Boynton, General Manager.

General Motors Deal Still Pending

Rumors, and then some more rumors, all false, with regard to the financial plans of the General Motors Company have been vigorously circulated during the past week. The sale of bonds to Chicago and Michigan capitalists has been alleged and denied, and the same may be said for the Boston deal which is said to involve $2,500,000, and Tuesday and Wednesday of this week a report outlining an immense underwriting of the whole General Motors project by metropolitan bankers, the terms of which were alleged to be a bond issue of $15,000,000, were all punctured almost as soon as they were floated.

As a matter of fact negotiations of the utmost importance to the company and the trade are pending at this time, but they have not been closed. The reports that will be published concerning the New York underwriting deal in particular has been thoroughly discredited.

At the offices of the company no official statement as to the status of affairs could be secured save that negotiations were under way looking to a solution of the financial problem involved.

Owing to the fact that the situation has numerous ramifications and is far from simple from any viewpoint, any forecast of the true result at this time would be impossible.

It is understood that the ultimate conclusion of the present negotiations contemplates entirely superseding anything in the way of tentative arrangements that may have been entered into. The situation could hardly be called *in statu quo,* because of the earnest efforts that are being made to accomplish something definite in the way of development.

Boston Auto Show Announced

Boston, Sept. 26—The Boston automobile show next March will not be a closed exhibition from which unlicensed cars will be excluded, as many people identified with motoring believed.

The show space will cover 105,000 square feet and the exhibition will open Saturday night, March 4, and continue through until March 11. The first floor will have the pleasure cars, the basement the commercial vehicles and the accessory men will be up in the balcony. The double-check system, in use at other shows, will be inaugurated here.

KisselKar 1911 Line Announced

Milwaukee, Sept. 26—The Kissel Motor Car Co., of Hartford, Wis., will build in the neighborhood of 1,500 cars for 1911, not including commercial or freight cars, the first models of which have just been issued. The 1911 KisselKar will be produced in five chassis types, as follows: 4-30, 4-50, 6-60, 6-70 and a 4-50 special, all being adaptable to various forms of bodies. The 1911 models contain few radical changes, but show a general refinement and the general lowering of the car.

The principal change is in the frame, which will have a double drop on all models excepting the Western Special, a new model placed on the market for the first time. With 36-inch wheels and 4-inch tires provided on these models, an unusual clearance is given. The wheelbase of the car has been generally lengthened.

The system of braking is changed, the double internal brake giving way to one internal and one external excepting in the 4-30 chassis. Front axles will remain the same, excepting that spindles are changed, lowering the car one and one-half inches. The tie-rod will be on the rear and the steering arm above the axle. The clutch is improved by adding a little more face. Full universal is provided between clutch and transmission. In the motors the only change is that the oiling system is self-contained force-feed in the oil basin.

The radiator design is the same and is again distinguished by the white and blue enamel circular name-plate in the upper left-hand corner.

First Aeroplane Crosses Alps

Brigue, Switzerland, Sept. 23—The illustrations as here afforded are of the first attempt made by Georges Chavez, taken during the flights he made just before he succeeded in crossing the Alps in his last flight, ending in the death of this daring aviator. He had made numerous efforts to accomplish this task, but on each occasion he found the pass hid away in a cloud bank and he was persuaded to turn back. At 1:40 p. m. on the day of his final attempt he found the conditions satisfactory; he started from the station at Brigue in the presence of numerous spectators. He negotiated the Simplon at a height of 450 feet, and had all but won the prize of $20,000 offered by the Italian society when he met his sad fate; a gust of wind took him unawares and his life was the forfeit. The accident took place at a point near Domodossola on the Italian side of the Alps.

Doings in the East

IMPROVEMENTS AT THE MAXWELL PLANT—SYRACUSE RUN POSTPONED ON ACCOUNT OF WEATHER—POPE COMPANY'S FAVORABLE STATEMENT—FRANKLIN FORMS A SELLING ORGANIZATION

—The Abbott-Detroit will be handled for 1911 in Rhode Island by the Whittem Motor Vehicle Co., of 200 Meeting street, Providence.

—The Bison Motor Sales Co., of Main and Barker streets, Buffalo, N. Y., will handle the Abbott-Detroit for 1911 in addition to the K-R-I-T.

—The Howard Demountable Rim Co., formerly located at No. 1411 Race street, is now installed in new headquarters, 324 North Broad street, Philadelphia.

—The Danbury, Conn., Agricultural Society will give a fair commencing October 3 and continuing until Oct. 8. An automobile show and speed trials will be among the features of the fair.

—The Greenville Metal Products Company has increased its capital from $250,000 to $600,000, and will make big extensions to its plant at Greenville, Pa., where automobile parts are manufactured.

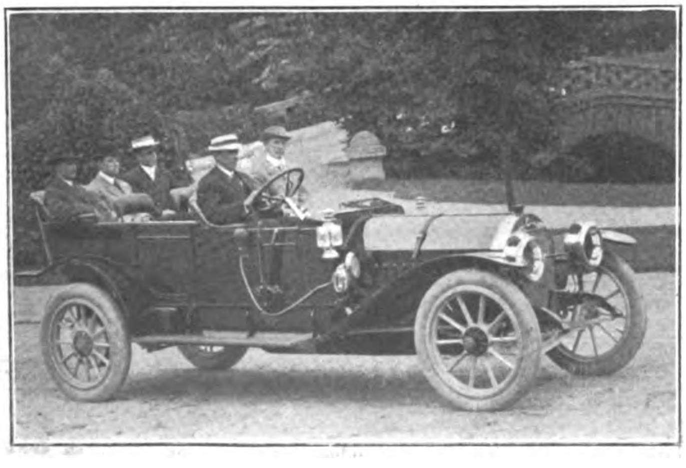
—Thos. J. Morthway, of 92 Exchange street, Ford agent at Rochester, N. Y., has taken on the Abbott-Detroit and is building an addition to his present garage and salesroom to accommodate the new line.

—The mammoth new garage of the Woods Electric Co. on Twenty-first street above Market, Philadelphia, is rapidly assuming definite proportions. It is expected to have the garage proper ready for business October 15.

—The T. C. Bradford Automobile Co., of Wilmington, Del., has taken the agency for the Hudson car for the peninsula, which comprises all of the State of Delaware, nine counties on the eastern shore of Maryland and two Virginia counties.

—Transformation of the Kingsland Point and Tarrytown plants of the Maxwell-Briscoe Motor Co. is being accomplished by the reclamation of about twenty acres of flooded lands between the plants. Several additional buildings will be erected on the sites thus made and the establishments will be practically connected.

—The New Jersey Automobile and Motor Club, leading the fight for remedial motor legislation in the State, intends next week to communicate with the office seekers of the State, asking their views on the motor situation. The big Newark club will then advise the 25,000 motorists of the State as to which candidates are aligned with them in their demands for more reasonable motor laws.



First 1911 six-cylinder Premier touring car—Designer George A. Weidely at the wheel, President Harold O. Smith beside him. In the tonneau are Treasurer Horace B. Hewitt, W. McK. White, advertising, and R. W. Macey, sales manager

—"What the Motorist Should Know," a handsomely made little booklet on proper lubrication, has been issued by the Vacuum Oil Company, of Rochester, N. Y. Aside from general information on the subject of motor lubrication, the book contains a list of 281 makes of automobiles with recommendations as to the variety of oil best fitted to each, in the opinion of the company.

—Of interest to the motoring public is the second annual statement of President Albert A. Pope of the Pope Manufacturing Co. to the stockholders for the fiscal year ending July 31, 1910. According to the president's report, the sales for the past year were $4,010,199.94, which represents an increase of $1,106,458.53 over the preceding year. The net earnings amount to $745,398.87.

—The Franklin Automobile Company, a selling organization dealing exclusively in Franklin automobiles, will hereafter be the distributor of all motor cars made by the H. H. Franklin Manufacturing Company. This company has branches in the following cities: New York, Boston, Chicago, San Francisco, St. Louis, Pittsburg, Buffalo, Baltimore, Cincinnati, Rochester, Cleveland, Albany and Syracuse.

Inspecting the Vanderbilt Cup Course in a Regal

—H. B. Larzelere, formerly sales manager of the Chadwick Engineering Works, has organized the Nance Motor Car Company in Philadelphia, which will build a popular-priced six-cylinder car. Mr. Larzelere will be president and general manager of the new concern and N. H. Adams head of the sales and advertising departments. The Nance company will shortly announce its full factory personnel and delivery dates of the new automobile.

—Negotiations have been completed by William P. Herbert. head of the General Motor Car Co., with the Rauch and Lang Carriage Co. of Cleveland, Ohio, for the agency in the Philadelphia territory of the latter's line of electric pleasure vehicles. The General Motor Car Co., which also represents the Lozier, likewise announces three additions to its selling organization—Keene Carruthers, of New York, A. Paul Oliver and Thomas J. Denney.

—The Syracuse *Herald* sociability run, scheduled for last week, had to be put over to Saturday on account of a severe rainstorm. There are over 100 entries for it. A picturesque trip is afforded through Camillus, Elbridge, Auburn, through the Owasco Lake Valley, Skaneateles Lake, Marcellus to Syracuse. The entire route is 74 miles. A secret time is set and the car coming nearest it is awarded a trophy cup, and there are also other prizes.

—Charles L. Stackpole has acquired control of the Yonkers Garage at Yonkers, N. Y.

—M. Zimbrich has purchased the salesroom and garage of the Geo. J. Arnold Co. at 103 Lexington avenue, corner E. Genesee street in Syracuse, N. Y., handling the Stoddard line.

—Walter R. Lee, secretary and general manager of the New York Automobile Trade Association, has been appointed assistant general manager of the Carhartt Automobile Sales Company of New York.

—The Pullman car is again represented in Boston, this time by the G. H. Proctor Supply Company.

—E. F. McDonald, Jr., has assumed the management of the Central Auto Sales Company, with offices in W. Genesee street, Syracuse.

—Albert M. Pearson, for a long time connected with the truck department of the Packard branch at Philadelphia, has resigned to accept a place with the Boston branch of the White Co. as manager of the commercial department.

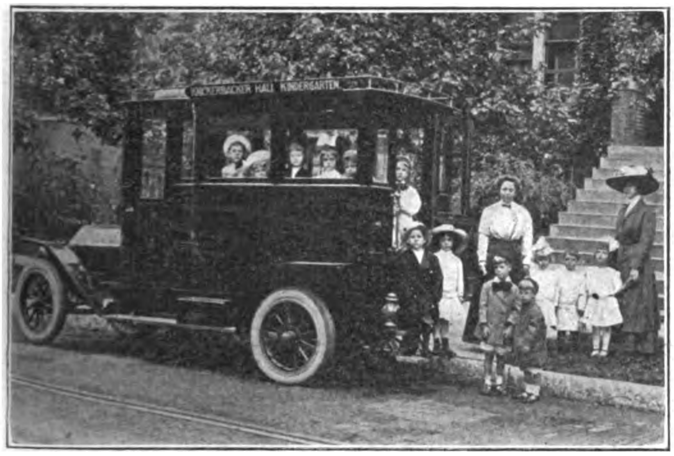
The South and the Coast

AUTOMOBILE CLUB OF MARYLAND GROWING—ATLANTA'S NEW MAKERS SECURE TEMPORARY PLANT—PACIFIC HIGHWAY ASSOCIATION ORGANIZED

—Multonomah County, Ore., is expending $120,000 annually on roads in that county.

—The Moon car is being represented in Baltimore by Cooper & Upton, 2312 Madison avenue.

—Marcus Blanchard has taken the agency for the Everitt car for Santa Clara County, Cal., with an initial order of ten cars.



Overland 'bus by means of which Indianapolis kindergarteners are enabled to defy the weather

—A sales branch of the E-M-F Motor Car Company has been established in Wilmington, Del., with E. G. Brown as the manager.

—J. L. S. Snead, formerly of San Francisco, but now of Portland, has opened a branch distributing office for the K-R-I-T Motor Sales Co., at 276 Union avenue.

—E. B. Waterman, of Medford, Ore., has accepted the agency for the Speedwell car at that point. He is also vice-president of the Oregon State Automobile Association.

—A. M. Brown, of the Hiland Automobile Company, Pittsburg, Pa., which handles the Peerless line, has accepted the management of the H. O. Harrison, Los Angeles, business.

—Under the management of Azariel Smith and Chas. W. Cleveland, formerly of Toledo, O., the Hupp Motor Company has opened an agency in Portland, at Seventh and Couch streets.

—Residents along the Liberty Pike near Harrisonville, Baltimore county, celebrated the closing of the toll gate in that vicinity by burning a replica of the toll house and gate. The road is now a State highway.

—New agencies are constantly being established at Portland, Ore. The latest to enter the field is the Haynes Company, which has established an agency, and a large garage will be secured on "Gasoline Row" early next month.

—The Zell Motor Car Co., of Baltimore, will become the agents for the Hupmobile October 1 for the State of Maryland and the city of Washington. The Zell Co. also handles the Chalmers-Detroit, Peerless and Hudson.

—The Automobile Club of Maryland has ushered in the Fall by admitting 22 new members. These include many of the most prominent business and professional men of the city and one lady, the latter being Mrs. L. Marshall.

—F. E. Cohen & Brother, Portland, Ore., besides handling the Maxwell during the next season, will be agents for the Columbia car and the Sampson trucks. The Columbia car has not been represented in Portland heretofore.

—The McCarty Automobile Company, of Spokane, has been incorporated, capital, $25,000, with L. D. McCarty president and general manager. A temporary office will be opened in the Eagle block. It will handle the Rambler.

—The Ajax Auto Traction Company, of Kenton, Wash., has commenced the erection of its plant, which will be 80 x 200 feet in size. It will engage in the manufacture of gas engines for autos, auto trucks, marine and stationary engines.

—The Primo Motor Company, Atlanta's new automobile maker, has secured a temporary plant. It is located in Atlanta, on the Georgia Railroad, and contains 15,000 square feet of floor space. Machinery will soon be installed in this building.

—Edward B. Zane, who has been Spokane, Wash., manager for Nute & Keena, handlers of the Packard, has bought the Eastern Washington territorial rights, and has put in orders for a number of 1911 Packard cars. He will continue as heretofore at 1012 First avenue.

—The Pacific Highway Association of North America was organized September 19th at a meeting in Seattle at the Arctic Club, following a banquet given by the Automobile Club of Seattle to visiting autoists from all the important cities of the Pacific Coast. This is the outgrowth of the Western Automobile Association. The new association will have as its principal object the promotion of the construction of an international highway along the Pacific Coast from Canada to Mexico.

Great Western 1911 semi-torpedo—General Manager E. Mack Morris at the wheel. President Milton Kraus beside him. In the tonneau are Secretary R. H. Bouslog, Vice-President; A. L. Bodurtha and Superintendent Paul Creighton.

Middle West News

BRODESSER TRUCK COMPANY MOVES FROM MILWAUKEE TO JUNEAU—GARFORD AND KISSEL COMPANIES LICENSED UNDER SELDEN PATENT—MANY AGENCIES AND BRANCH HOUSES ESTABLISHED

—The agency for the Cole "30" has been secured in St. Louis by A. A. Franklin & Company.

—E. L. Dundon has been appointed St. Louis agent for the Jenkins emergency automobile wheel.

—Jose M. Sojo, of San Juan, Porto Rico, has signed up with the Abbott Motor Co. for the agency of the Abbott-Detroit car.

—The Schreiber Motor Car Company of Milwaukee, Wis., has taken the agency for the Hudson car in addition to the Locomobile and Haynes.

—The Steely Auto Engine Company, with a capital stock of $150,000, has just been incorporated to make automobiles and light delivery wagons at Detroit.

—A. F. Eckstein, of Milwaukee, Wis., has become general manager of the Highland Garage Company, Twenty-seventh street, near Highland boulevard.

—J. V. Black, recently of Detroit, is to take charge of the Goodrich business in Cincinnati. He will be located in the Goodrich Tire Company's new building on Race street.

—Announcement is made that The Garford Co., of Elyria, O., and The Kissel Motor Car Co., of Hartford, Wis., have just been granted licenses under the Selden Patent No. 549,160.

—The Ritter Automobile Company has been incorporated at Madison, Wis. The capital stock is $25,000. Henry R. Ritter, J. C. Harper and Homer E. Webster are the incorporators.

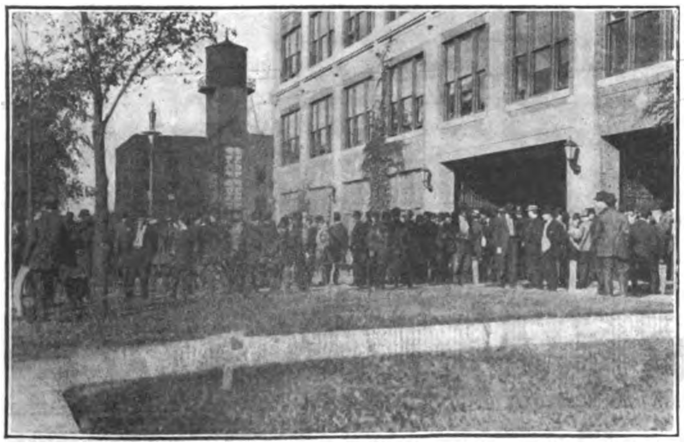
—J. H. Diehl, for many years a Cleveland business man, will have charge of the factory branch which will be established in Cleveland by the Louis J. Bergdoll Motor Co. of Philadelphia.

—H. B. Waltz, who has been identified with the selling end of Cleveland automobile agencies for some time, has joined the sales force of the Sterling Motor Sales Co. and will sell the Cutting car.

—The Gilchrist Motor Sales Company, with headquarters at the Empire Garage on Seventh street, Cincinnati, is now handling the "Matheson Six," formerly represented by the J. S. Stevens Auto Company.

—Charles M. Culp, of South Bend, has been granted a patent on an emergency tire which may be attached to an automobile wheel. The tire is made up of six parts, which may be stored under the seat of the machine.

—At the adjourned annual meeting of the Atlas Drop Forge Company, at Lansing, Mich., the board of directors was reelected. The board elected the following officers: President, R. E. Olds; vice-president, R. H. Scott; secretary-treasurer, S. H. Carpenter.



Men at Packard factory waiting for time office to open in order to obtain positions in answer to "Help Wanted" ads

—McAlister Brothers Motor Car Company, which handles the "Cadillac" car in Pittsburg, has just moved into its big new building at Baum and Beatty streets, East End, one of the most complete automobile plants in the country.

—M. K. Enders, of New York, who has been connected with the Ford Motor Company for five years as traveling representative of the New York branch, has taken charge as manager of the Ford Motor Company's branch in Cincinnati.

—G. H. Wallis, of Corliss, Wis., has been appointed chief engineer of the Kelly-Racine Rubber Co., which is now erecting a $500,000 plant at Racine, Wis. Mr. Wallis has been erecting engineer for the Corliss Engine Co., at Corliss, near Racine.

—The Mitchell-Lewis Company, of Racine, Wis., has placed with the Laporte Carriage Company, of Laporte, an order for 1,000 five-passenger automobile bodies. The order is the largest the Laporte concern has ever received and amounts to $140,000.

—Walter Egerton, who has been connected with the Barclay Auto Company, of Minneapolis, in the capacity of salesman, for several seasons, resigned his position last week to go with the Winton Motor Carriage Company's Minneapolis branch.

—At the annual meeting of the Longdin & Bruegger Co., of Fond du Lac., Wis., manufacturers of tops, canopies, dashes, etc., it was decided to enlarge the present plant by the construction of a three-story addition, 30 by 40 feet, and remodel the old works.

—A. H. Wyatt and W. H. Kitto, of Cleveland, will build an auto truck plant at Lisbon, Ohio. A fund of $25,000 is being raised by the people of the city for the purpose of buying stock in the new concern. Present plans contemplate placing the plant in operation this fall.

—The Regal Motor Car Company of Detroit has established its own factory branch in Minneapolis for the distribution of this make of vehicle throughout the Northwest. Headquarters have been established at 418 to 420 Third avenue South. The firm name will be the Minneapolis Regal Auto Company, and J. P. McGuire will be in charge.

—The Brodesser Motor Truck Company of Milwaukee, Wis., has completed the formality of changing its place of business to Juneau, Wis., by filing amendments to its articles of incorporation to this effect. Work on the new plant at Juneau is being rushed and it is possible that occupancy will be given on December 1 instead of January 1.

—The Abbott Motor Co., of Detroit, will be represented at the Vehicle and Implement Show in the Coliseum Building at Chicago the week of October 10 to 15 by three cars, a roadster with fore doors, a fore-door touring car and the regular touring car and stripped chassis. The exhibit will be in charge of Sales Manager V. K. McBride and a corps of experienced demonstrators.

—The Chase Motor Car Company, of New Bremen, O., has been incorporated with an authorized capital stock of $50,000. There are thirty-five stockholders in the company. The plant of the Grothaus Laufersieck Company has been secured, and motor trucks of the commercial variety will be manufactured. The incorporators are J. H. and Edmund Grothaus, J. F. Laufersieck, Otto J. Doesel and Louis Huenke.

—The Rockhoff Foundry Company, of Fostoria, Ohio, has commenced work on a new factory building, 40 x 100 feet, at Mishawaka, Ind. The concern is an extensive manufacturer of crankcases for marine and auto engines. The company makes a specialty of heavy aluminum castings and at present has large contracts with the Apperson and other automobile concerns for thousands of crankcases for immediate delivery.

Packard Taking On, Not Laying Off Men

Contrary to the rumor which has had widespread circulation, the Packard Motor Car Company denies that it has laid off several thousand men at its Detroit plant. In proof of its assertions the company, through General Manager Alvan McCauley, has given out a statement that the company is taking on men at the rate of about 100 a day as its new buildings are finished or new machinery is installed.

In this statement it is asserted that the force of over 5,000 men is being constantly added to and that 500 more men will be put to work within a week.

The following advertisement was inserted recently in the Detroit newspapers:

"WANTED—Automobile workers in all departments—machine operators of all kinds, assemblers, body makers, painters and finishers.

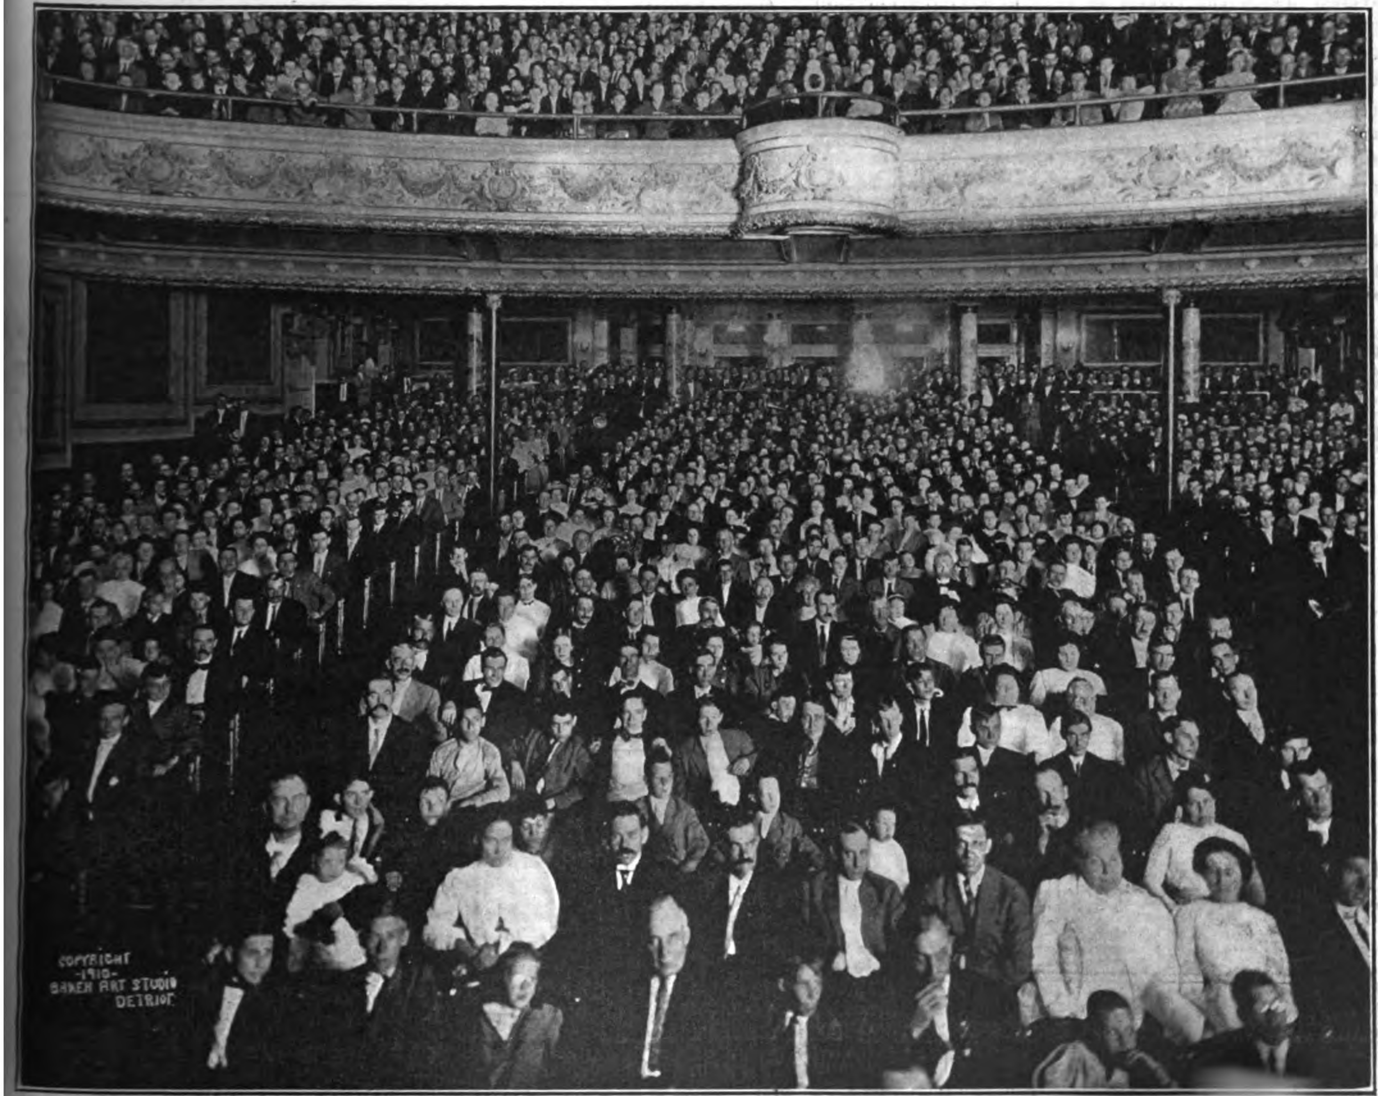
"Packard Motor Car Company."

The Packard Company shows in the accompanying illustration how it was answered.

On page 444 of our issue of September 15th we stated that the equipment of the Stoddard-Dayton stock cars includes a storage battery, which is not the case. The ignition system installed on this make of car comprises a Bosch high-tension magneto and a set of dry cells, constituting two independent means for igniting the charge.

Goodrich Succeeds with Campaign of Education

Some time last April the B. F. Goodrich Company, maker of the well-known Goodrich tire with a large establishment at Akron, Ohio, decided to conduct an educational campaign with a view to acquainting automobilists with the tire situation as it is hoping, perchance, to make a long stride in the direction of the more or less complete elimination of the many foolish ideas that pass current among automobilists in relation to tires. A series of moving pictures were brought together, they representing every phase in the manufacture of tires as the work is done by the Goodrich concern, beginning with the tapping of the trees in South America to obtain the supply of latex passing along and into the plant where the various steps in the process are clearly depicted, and the final product is shown in service. An engaging lecturer conducted this campaign and the motion pictures were shown in Ohio, Pennsylvania, New York, New Jersey, West Virginia, Maryland, Connecticut and Maine, but it is understood that the campaign will continue until the entire country is covered. The entertainment is heralded under the caption "Tree to Tire," and the illustration here presented represents a body of 2,500 persons who were in attendance at the Light Guard Armory in Detroit, and it is a noteworthy fact that upward of 2,000 persons were turned away. One of the surprises of this campaign is represented in the interest that women folks are taking; probably 20 per cent. of the attendance is made up by ladies. The company finds ample evidence of the fact that education has real merit.



BIG CROWD IN LIGHT GUARD ARMORY, DETROIT, LISTENING TO GOODRICH TIRE LECTURE [illegible] TIRE"

Continental Motors

A MOTOR OF COMPACT AND CLEAN DESIGN SUITABLE FOR AUTOMOBILE WORK; PARTICULAR ATTENTION HAS BEEN PAID TO LUBRICATION, COOLING AND ACCESSIBILITY

THE first thing that strikes one in looking at the Continental motor is the absence of unnecessary parts and the compactness and cleanliness of the design. One great object that seems to have been achieved is the accessibility of all parts that require dismantling from time to time for the purpose of adjustment or cleaning.

The motor here shown is the new Model "T," having a bore of 5 inches and a stroke of 5 3-4 inches; it is of the four-cycle type with the cylinders cast in pairs, and the inlet and exhaust valves placed on opposite sides. This style of construction adds to the cost of manufacture and slightly to the weight, but obviates certain difficulties sometimes encountered with piping and get-at-ability in other systems.

The timing gears are all placed in a clean housing in front, with a plate that is easily detached. The suspension lugs are of ample proportions and are so made that the alignment can be easily made by the aid of packing pieces under the extensions that rest on the frame. These can clearly be seen in Fig. 1. The same gearing is utilized to drive the pump and the magneto, a Bosch high tension, which can easily be dismantled by unscrewing the holding-down bolts under the base plate. The pump is fitted with two stuffiing boxes on either side of the main body. Behind the magneto is situated the main oil filler of ample dimensions, with a cap that serves the combined purpose of cap and vent plug. The exhaust manifold is particularly clean and it will be noticed that there are four outlet ports giving a quicker passage for the exhaust gases besides reducing the heat over the valve heads.

The water connections are made at the lowest point of the circulation, and the easy bends are conducive to an even flow for the water.

At the rear end of the lower half of the base chamber there is a large plug to empty the oil, and as the incline of the casting is toward the rear, all the oil can be emptied with the one plug.

The amount of oil in the base, which when full holds four gallons, is registered by a neat device which is located between the cylinders and can easily be seen. Besides the splash system of lubrication there is attached to this motor a new patent force-feed oil pump, shown in Fig. 2, being under positive pressure. One stream of oil is fed in over the gears, another to Nos. 1 and 2 connecting oil bushings and a third to connecting-rod bushings Nos. 3 and 4. All oil before going into the pump must pass through a thorough cleansing process which prevents all impurities from reaching the bearings.

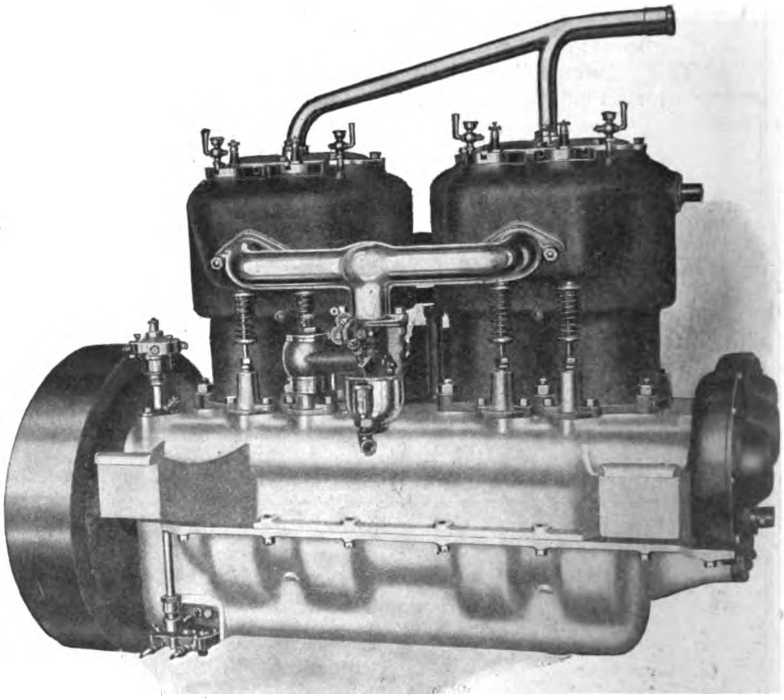


Fig. 2—Inlet side of engine, showing carbureter and oil pump

The crankshaft and camshaft bearings, which are very liberal, are of white bronze. The connecting-rod and main bearings are provided with liners 0.002 thick, so that the slightest wear can be easily taken up.

The balancing of the motor has been a matter of special study, the flywheel and crankshaft being balanced separately and all reciprocating parts are weighed into less than one-half ounce.

The inlet side of the engine, Fig. 2, clearly shows the absence of complication, the only parts being the Schebler carbureter and the distributor for the coil and battery ignition.

All the valve lifters are fitted with adjustable feet so that all wear can readily be taken up. Pet-cocks are fitted, and on the front cylinder provision is made for fitting a fan bracket.

The engine is manufactured by the Continental Motor Manufacturing Company, Muskegon, Mich., which makes a specialty of the construction of all kinds of motors for marine and automobile purposes.

VOL. XXIII NEW YORK—THURSDAY, OCTOBER 6, 1910—CHICAGO NO. 14

THE AUTOMOBILE

Line Up Before Start

IN a race that broke four records, the Alco entry, Number 18, won the sixth running of the Vanderbilt Cup, Saturday. It was the fastest, closest, largest in point of entries and by far the hardest that has been run for the cup. The Marmon car, Number 25, was second, so close to the winner that the result was not definitely known until the officials had made some careful calculations to determine that the Alco had a margin of about 24 seconds. National, Number 10, was third, 1 minute and 6 seconds behind. Eight cars finished the contest according to the official figures and two others came up to the tape in time to have their status definitely fixed before the race was called off. These in the order of their finish were as follows: National, 31; Lozier, 2; Pope-Hartford, 17; Simplex, 11; Benz, 7; Stoddard-Dayton, 15; Pope-Hartford, 22, and National, 1. Ten of which were stock cars.

Harry F. Grant, driver of the winner, averaged 11:20 for each round, without reference to tire trouble, of which he had little. Once he stopped nearly four minutes while a tire was being replaced; another time such a change required nearly two minutes, and in the twentieth round he was held about as long a time when his lead was less than two minutes, but was able to get going before the wasp-colored Marmon had quite time enough to push its yellow and black body to the front.

The race of the Alco was not spectacular in any respect. The car was always prominent and went to the front at the right time, managing to last long enough to win.

Not many of the quarter-million spectators selected the long-hooded, black six-cylinder car to repeat its victory of last year, and not until the race was half over did the running of the car impress itself on the general public. Then, when the rushing, driving rivals who had been in front succumbed for one cause or another, the Alco came into its own and landed the victory in one of the fiercest finishes ever witnessed here or elsewhere in such a long race, the margin being less than a half-minute.

The Marmon, while beaten, was not disgraced. It did not have the giant power of its conqueror by 22 horsepower and yet it was only beaten half a mile in nearly 300. Its driver, Joe Dawson, made a brilliant race of it all the way and looked all over a winner at one stage.

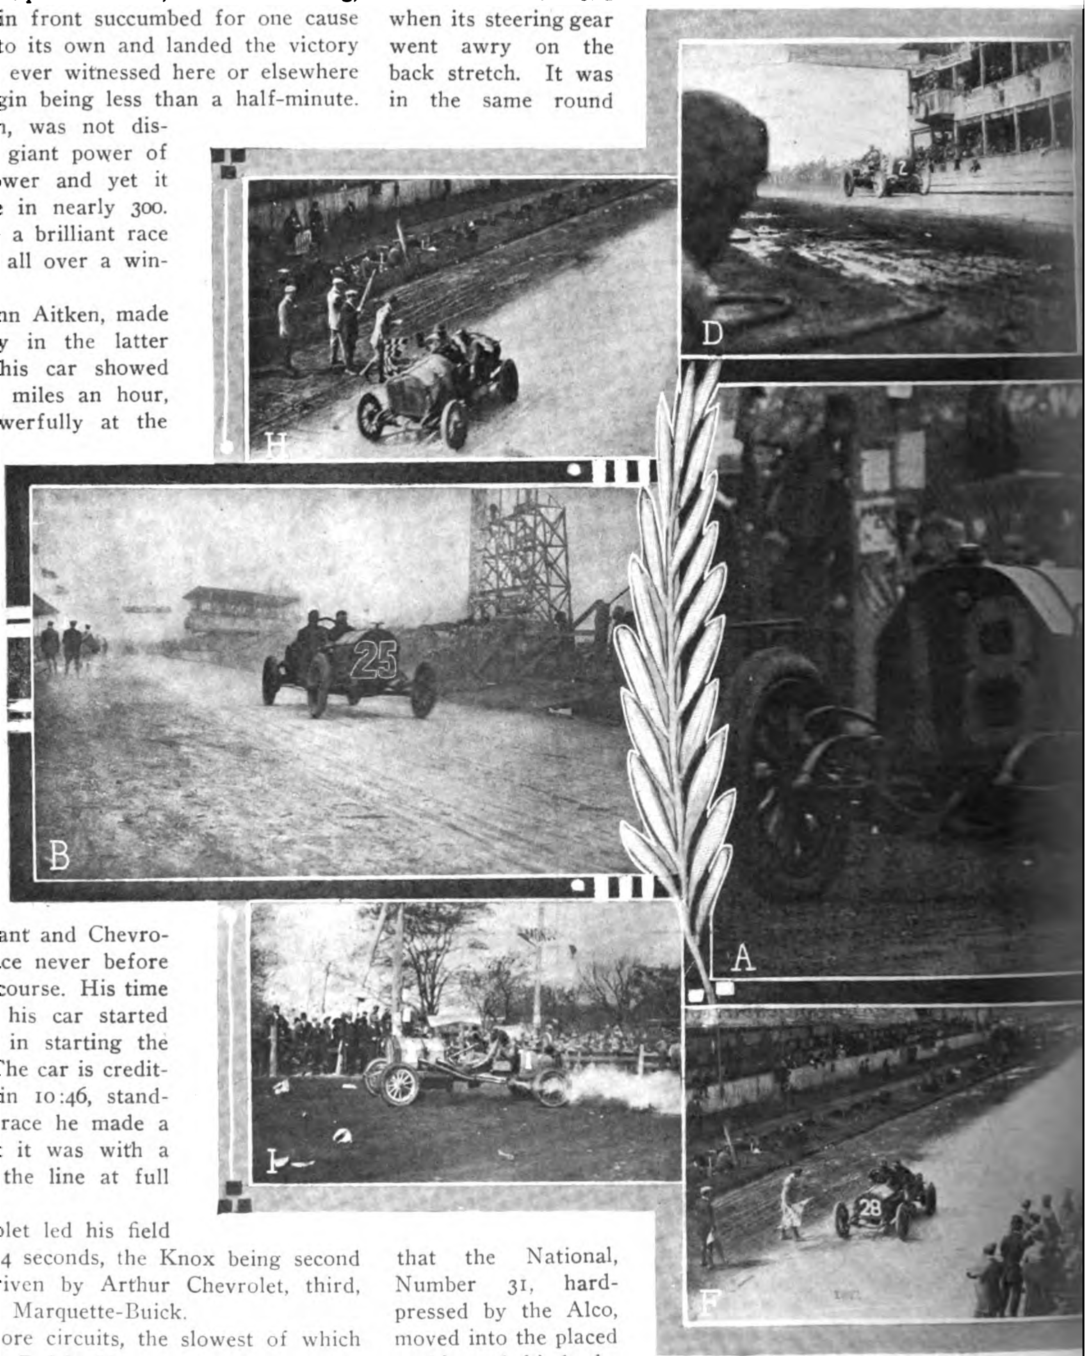
The National, driven by John Aitken, made a gallant showing, especially in the latter portion of the struggle. This car showed one round in 9.31, nearly 80 miles an hour, and was swinging along powerfully at the end.

Just at 6 o'clock the record-breaking field was sent away, with Livingston's National in front and Belcher's Knox as rear guard. One of the Oldsmobiles, Number 5, broke its oil pump on the way to the line and was withdrawn. All the cars got away in good order except Number 29, Marquette-Buick, driven by Louis Chevrolet, which stalled its motor just after the getaway. It required only about 10 seconds for Charles Miller, mechanician of the car, to re-crank the giant and Chevrolet drove that round at a pace never before equaled for a first lap on this course. His time was taken from the second his car started and includes the time spent in starting the engine for the second time. The car is credited with making the circuit in 10:46, standing start. Last year in the race he made a round under 10 minutes, but it was with a start where he moved over the line at full speed.

Despite his mishap, Chevrolet led his field at the end of the round by 14 seconds, the Knox being second and the Marquette-Buick, driven by Arthur Chevrolet, third, neck and neck with Burman's Marquette-Buick.

Tearing along for seven more circuits, the slowest of which was done in 10:33, Marquette-Buick, Number 29 held its lead until midway of the ninth lap. Repair work of nine minutes deprived him of the lead before the finish of this round and Burman's car assumed the pacemaking. That car had been following the lightning pace of Number 29 ever since the start, with the Knox second for three laps, when valve troubles put it out of the running. Dawson's Marmon had taken up third place when the Knox retired and moved into the runner-up's position and Marquette-Buick, Number 29, fell out for repairs.

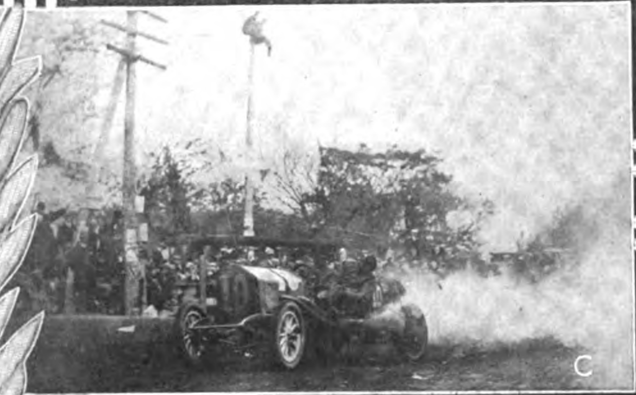
Burman's car stood the pace for just one round, when radiator troubles intervened and the car was taken from the race.



A—Winning Alco at Westbury; B—Marmon car which finished second; D—The Lozier passing the grand stand; F—Apperson being flagged; H—No. 15 Stoddard-Dayton which finished; I—National No. 1 at Westbury turn

This resulted in the Marmon's assuming the lead in the tenth round and holding it for eight circuits of the course. In the ninth lap the ultimate winner first showed prominently, when it finished in third position, 3:40 behind the Marmon. Disbrow's National, Number 31, displaced the Alco for a time and Louis Chevrolet's car, having completed its repairs, was rushed up to third place and eventually traded places with the National contender. But in the fourteenth lap the Marquette Buick was delayed 17 minutes in making repairs and in the next round met with a fearful end when its steering gear went awry on the back stretch. It was in the same round that the National, Number 31, hard-pressed by the Alco, moved into the placed positions behind the flying Marmon. One round at that pace was enough for Disbrow's car and the Alco dropped in behind the pace, about three minutes to the bad. John Aitken's National, Number 10, rushed into third position in the fifteenth round and made a bid for second in the two succeeding laps.

In the eighteenth the Marmon had a bad time, losing nearly nine minutes in repair work, resulting from an accident. This moved the Alco into the lead, with the National, Number 10, second, just ahead of the Marmon, which was four minutes behind the pace. From there to the finish the Marmon steadily decreased the distance between it and Grant's car, and when the latter stopped for a quick tire change in the twentieth lap the yellow jacket nearly reached him. But the black car had something left and in the fiercest drive ever witnessed in a Vanderbilt Cup race managed to last long enough to win by a margin of a trifle less than 25 seconds. The Marmon, going over 68 miles an hour for the lap, was second, and the National, pulling up a little when it was apparent that it could not displace either, was third.



C—No. 10 National at Westbury; E—National No. 31 passing the stands; G—No. 7 Benz, driven by Hearne, passing Westbury; J—The bullet-nosed Pope-Hartford No. 22; K—Amplex No. 9 on the course near the Hicksville turn.

The winner set a new mark for speed in this race, turning the 278.08 mile course in 4:15:58, or at a rate in excess of 65.18 miles per hour. Throughout the whole race Grant drove as if his car was the only one in the contest. He attempted no wild spurting. He simply reeled off the entire course at the rate of 67 miles an hour and tried to make up little of the time lost in making tire changes. It was a wonderful exhibition of nerve, but it lacked the vim and dash of some of his rivals. Aitken, driver of National 10, tried for the lead in the thirteenth lap, when he opened wide his throttle, declined to shut down on the turns and made the circuit in 9:31, the fastest time ever made in the contest, being nearly 80 miles an hour. Tire trouble in the earlier stages had dropped him a little too far to the rear and this one wild round landed him up with the leaders.

Early Friday evening the annual procession of automobiles started for the course from New York. As the hours wore on, the single line of cars became a double file and later a squad of four abreast on the main thoroughfare. By hundreds and thousands the cars came, choking the roads and carrying such an army as never before witnessed the big race. The number of cars at the course was estimated as high as 20,000 and the crowd that saw the race was measured up to the half-million mark. It is likely that 15,000 for the cars and 250,000 for the crowd would be conservative figures. Everybody was good-natured during the long watches of the night, but there was little apparent enthusiasm after the big race started.

The course was very rough in some spots, and the majority of the mishaps to the cars were caused by the tremendous jolting given them on the back stretch.

One danger that seemed possible and worried everybody before the race commenced did not develop. That was the likelihood of collision when two or more cars tried to pass on the narrow roads. The rule was made that the slower would have to keep to the right when a passage was attempted, and it worked very well.

In a word, from the viewpoint of automobile racing, the Vanderbilt Cup of 1910 stands out as the greatest of the series. It was gallantly run and won.

The miraculous skill of the drivers engaged in this race can be best chronicled by saying that in one of the laps thirty-seven cars were on the course at the same time. How they avoided a general mix-up speaks volumes for their skill and discipline.

The Wheatley Hills Sweepstakes developed a new claimant to speed honors when Falcars finished first and second in the 15-lap race on the Vanderbilt Cup course, which started an hour after the big cars were sent away. There were nine cars carded to go, but the Technical Committee disqualified the Correja entry because it did not conform with the stock car qualifications required under the terms of the contest. The Marmon got away in front and stayed there until the end of the seventh lap, when Gelnaw's Fal took up the running and won handily by over ten minutes from its teammate, which was driven by W. H. Pearce.

The Massapequa Sweepstakes, for still smaller cars than the Wheatley Hills, was won by a Cole "30," driven by Bill Endicott. An Abbott-Detroit, driven by Mortimare Roberts was second, and another Cole "30," handled by Harry Edmunds, was third. It was the luckiest sort of a win, for the Lancia entry, with a long lead, came to grief, turning turtle and going out completely. This left Endicott's car with a big margin of lead which he carefully maintained.

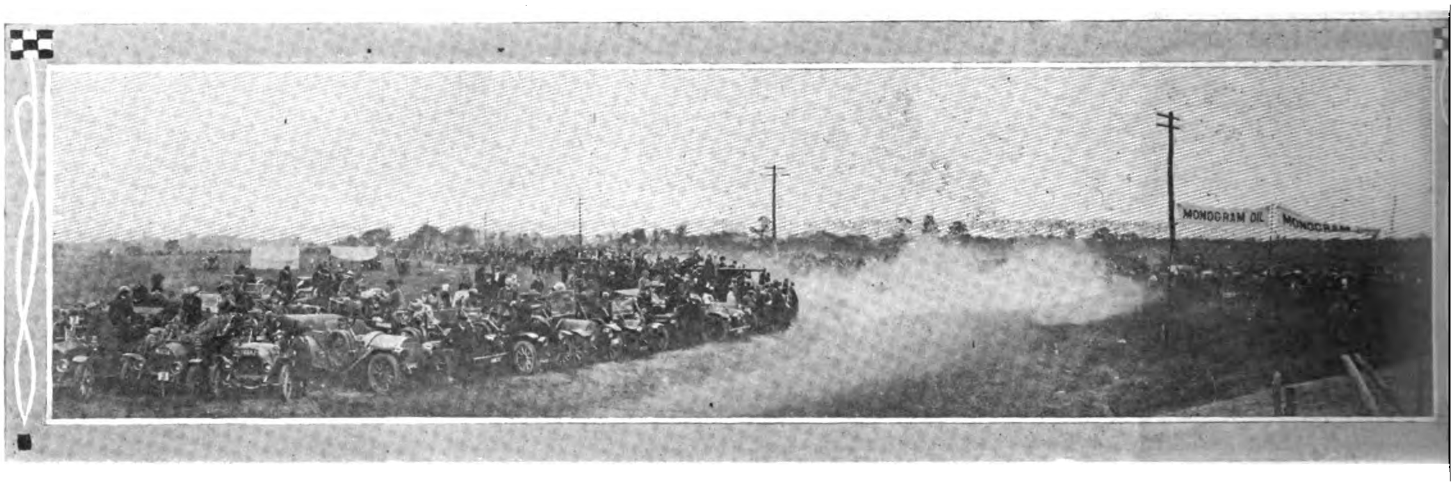
At the Massapequa Turn

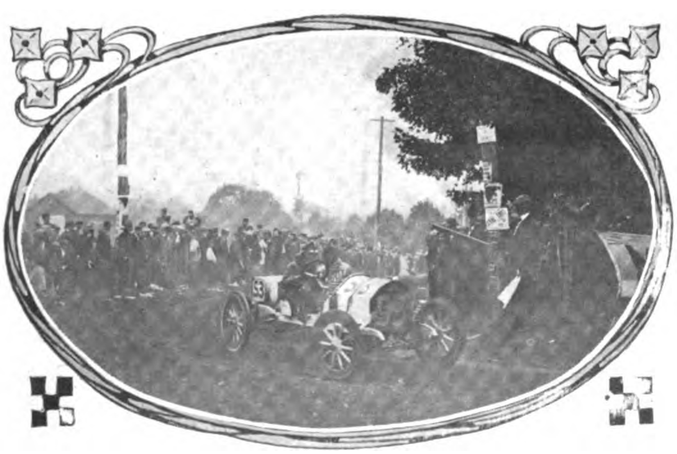
The Falcar finishing first in the Wheatley Hills Sweepstakes

THREE disabled racing cars, all red, marked a special curve, some 30 feet beyond the crest of the earth and gravel banking which had been provided at the Massapequa turn. The first marker, car No. 56, arrived at about 8:30, the second, No. 54, at 9 sharp, and the third, No. 6, at 9:40. At the beginning of the turn the banking consisted mostly of a reddish-brown earth, affording an effectual retarder for the front wheels which bored themselves into it, giving the momentum of the car a chance to raise the rear wheels so they would slew around more easily. And slew they did, with few exceptions, from the beginning of the race until about 8 o'clock, when most of the soft-earth banking had been distributed over the clothes of the spectators.



At the Massapequa turn, throwing up dust and stones out of the loosely-placed banking material

Further on in the turn the banking, being here largely composed of coarse gravel, was more resistant and its outer edge was raised into the air like the crest of a choppy wave, separated by an irregular trough from a cornfield in front of a farm where most of the pedestrian spectators had placed themselves in a fringe that wavered in and out as caution or curiosity dictated.

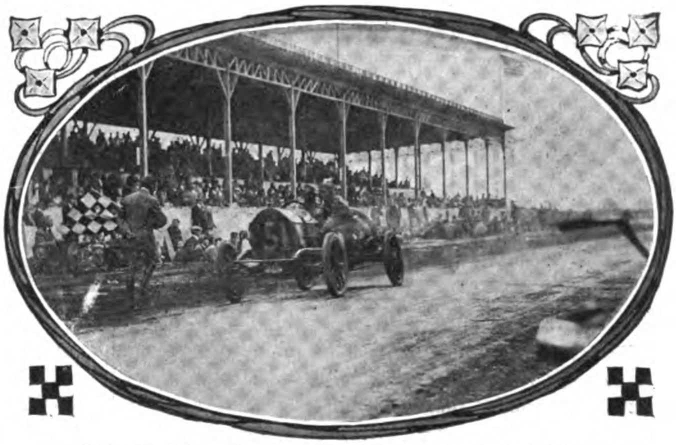


Abbott-Detroit car, No. 53, taking the Westbury turn

As the soft part of the banking was wearing down, the crest of the gravelly part seemed to move into the course by comparison, but the majority of the drivers had learned to know the spot and carefully hugged the middle of the road. Still the crest became more and more indistinct, and every now and then one or another of the flying monsters, less coolly controlled than it should have been, squeezed an inch or two off this treacherous ridge, narrowing the road by that much for the next man, and each time this happened the driver could be seen rightening his car with two sudden movements of his steering gear. Yet nothing serious happened for over two hours after the start of the race. If only one half of the actual number of cars had been in the race the banking might have endured the test to the finish, almost as well as if it had been backed up with twenty more wagonloads of material on the offside. It was getting monotonous. Reports of real accidents from other parts of the course were floating from man to man, and from automobile to automobile in the parking spaces, and here at the worst turn nothing happened. Perhaps it was just because it was so bad and all knew it. The speed of the cars was certainly quite moderate. Nothing like 60 miles an hour. Nothing to compare with the bold turns at Krug's Corner and Jericho in the early days when Lancia and Nazarro taught the young native idea how to shoot and the Vanderbilt Cup race was an institution for the promotion of foreign purchases and domestic improvements.

It seemed a good time for a belated breakfast. Probably all pessimistic views with regard to that banking were only the promptings of an empty stomach and lack of sleep. Rustic constables helped out the bracing morning air with surreptitious nips from flat bottles, ducking below the level of the crowd and leering in half-conscious betrayal of the impressive but misfit operatic policeman's uniform loaned them for the ocasion. Surely it was time for refreshment. In company with a sufficiency of roast lamb sandwiches and a bottle of mild Medoc the reporter sought a hospitable retreat. The repose behind a friendly stack of unhusked corn some 300 feet from the scene of action and apparently the only untaxed spot in the vicinity was slightly broken into by some faint signs of commotion. The parkers

WHAT A MEMBER OF "THE AUTOMOBILE" STAFF SAW AND HEARD AT THE FAMOUS CORNER WHERE DIRE THINGS THREATENED



Cole, No. 51, winning the Massapequa Sweepstakes

stood up in their vehicles. Young persons ran up toward the turn and soon returned chattering. No voice was raised. The decorum was perfect. Evidently some car had a little tire trouble. It was scarcely worth while to run up with a bottle in one hand and a sandwich in the other to examine the specific causes of something so trivial. It could wait. A car swished by. Another. The people turned their heads after them and turned around and looked in the opposite direction, toward the parkway, for the next one. Everything looked regular. And it was. The remarkably cool temper of the spectators made it so. The little incident which had passed so smoothly was indeed nothing but the disabling of car No. 56, driven by Padula. A leisurely post-prandial examination, ten minutes after the act, found the red car resting in the edge of the crowd, with short stumps of the right rear wheel spokes dug deeply into the soft ground. The whole felloe and the tire were gone. The wreck was guarded by two Abbott-Detroit men who were tired of answering questions and looked glum. A telegraph pole bore slight witness of an encounter, and the bystanders confirmed the inference that it had been hit by the right rear wheel of car No. 56, with the result mentioned. The pole was placed about 16 inches beyond the ridge of the gravelly banking, previously referred to, and the car had evidently straddled the ridge.

Scene at the Massapequa turn, where crowds congregated in the hope of seeing something happen

Precisely at 9 o'clock the Lancia car, No. 54, came sidling down the road. Before it reached the turn, which is really two blunt turns in quick succession, it could be observed running at angle of 10 to 15 degrees with its axis, like a dog trotting. Something was the matter with it, but by some strong effort it rounded the first part of the turn. Then it shot in a perfectly straight line slantwise over the banking and charged straight for the scattering crowd. A child or woman screamed, just once. The car swung around its left front wheel, clear around, pointing with its rear end forward. It looked as if it must have hit a number of persons. It had come to a sudden dead stop, and the driver, William Knipper, and his mechanic were carried to the roadside. Racing is a profession. The incidents and accidents of it are part of the business. A spectator whose name was given as Morris Levinson suffered a broken leg. Within a few minutes he was taken in the waiting ambulance to the Homestead Hospital. The crowd was thick around the scene. When it scattered, Knipper and his man were also gone. The car, draped on the roadside about 30 feet behind No. 56, showed a front axle twisted to a partial fracture at the left steering knuckle and a shaker bonnet that was also damaged.

Forty minutes later, when the end was in sight and while the fans were swapping notes and picking the winner, the Simplex car, No. 6, Ralph E. Beardsley driving, hove in sight and without any warning or indication that anything was wrong shot over the bank, following in the tracks of No. 56, and, in fact, bumped into the wreck of this machine so hard as to sever its rear axle from its fastenings by shoving the frame forward over it. Beardsley unlimbered his tall form from the cramped seat. He was unhurt, the mechanician likewise. And the car for a moment seemed good enough to resume work and was pushed into position for starting afresh. But closer inspection revealed something wrong, and its journey was ended then and there.

Stock Cars Prove Supreme

ALCO IN FIRST PLACE CLOSELY FOLLOWED BY MARMON, TWO NATIONALS, LOZIER, POPE-HARTFORD, SIMPLEX, BENZ, STODDARD-DAYTON, ANOTHER POPE-HARTFORD, AND THE THIRD NATIONAL, PRESENTING A STOCK CAR EVENT WITH A SINGLE RACING MACHINE, THE BENZ, AMONG THE CARS THAT COMPLETED THE FULL DISTANCE

SIX years ago, when the first Vanderbilt Cup Race was run, every entrant was a special racing car, designed and constructed specifically for racing purposes, and the cost of these special automobiles ranged all the way from twenty to sixty-three thousand dollars apiece. When the race was declared finished, there were but four of these special cars in the running, and of the four cars but one was of American design and construction, i.e., the Simplex, and it was in a state of bad repair at the end of the race. A review of the several events leading up to the Sixth Annual Race, just completed, would amount to a substantial re-statement of the above, excepting that from year to year American automobiles took the more prominent part, and even last year the American builders were censured by those who thought they knew all about it, because they persisted in using their stock automobiles in preference to building racing cars.

To the sporting fraternity it looked as if an automobile, to be able to compete in a great event, would have to be specially designed and constructed, utilizing the freak ideas of some abnormal mind, paying but slight attention to the regular and orderly thoughts and considerations that govern the acts of designers who obey the conventions and bow to the will of precedent. The Sixth Annual Vanderbilt Cup Race, as it terminated on October 1, is a monument to the acumen of the builders of American automobiles, the obverse side of which is inscribed. telling of the stupidity of all who put their faith in special racing machines, and who relied upon the patronage of sports, rather than upon their own good sense to guide them to success.

Disregarding, for the time, the fact that the stock automobiles that competed in the last Vanderbilt Race may have been tuned up for the occasion, and otherwise prepared for the strenuous work expected of them, the fact remains that substantially every one of the good performers were stock cars, whereas the special automobiles, almost without exception, were found by the wayside, wrecked beyond recognition, in some cases, practically beyond repair in all instances, and so thoroughly in disrepute because of their poor performance in competition with stock automobiles that it is a question whether or not any maker of cars will ever again risk his reputation by putting a specially built racing machine in competition with a sturdy stock car.

The newspapers everywhere are taking advantage of the headline material that is so much in keeping with their tastes and their needs; they point out that the track was in wretched shape, with dangerously banked curves, and all the other surface indications of lack of preparation, and there is ample evidence to be seen at every hand of the fact that it was a gruelling test for the cars, conducted under the most severe conditions imaginable, and what does it show? The automobiles that were in at the finish were all stock cars, excepting one, and that was the only foreign automobile in the race that made a showing worth talking about, and it finished eighth. From the winning Alco No. 18 driven by Grant down, including Marmon No. 25 driven by Dawson, National No. 10 driven by Aitken, National No. 31, driven by Disbrow, Lozier No. 2 driven by Mulford, Pope-Hartford No. 17 driven by Fleming, Simplex No. 11 driven by Mitchell, Stoddard-Dayton No. 15 driven by Harding, Pope-Hartford No. 22 driven by Dingley, and National No. 1 driven by Livingstone, the entire list belong in the stock car category. These models may be had by any automobilist who may care to purchase them, and these cars are built in the regular way, by routine methods in the several plants, and they prove that the regular way is the only way to attain truly reliable results.

Pursuing this line of thought to finality, it is only necessary to say that the cars that were running, but that did not conclude the twenty-second lap when the race was called off, belonged to the stock category also. This list of cars, beginning with the Amplex No. 9 driven by Jones (the only 2-cycle automobile in the contest), included the Oldsmobile No. 20 driven by Stillman, Houpt-Rockwell No. 26 driven by Linberg, Apperson No. 28, driven by Hanshue, and Jackson No. 19 driven by Scheifier. The Knox No. 32, driven by Belcher, is a member of the stock car family also, and while it failed to stay in the race up to the finish, the fact remains that it completed its first lap in 11 minutes and was only prevented from giving its customary good account because of a valve disorder, whereas the specially built racing machines showed lack of stamina, and were spilled by the roadside, in some cases being so completely disrupted that it would take an automobile expert to tell that they were originally intended for racing machines.

The absence of the Old Guard of foreign racing automobiles this year is the best indication possible to have of the fact that the makers of these special types of racing machines are fully alive to their uncertainties, and the foreign builders are cute enough to know that it is better for them to "rest upon their laurels" and try to survive on a "has been" basis than to struggle with the inevitable. There is nothing unusual about this attitude on the part of these makers; they have experience, and they know that a regularly built automobile is the product of evolution, whereas a special machine is the progeny of a revolution.

The very fact that the foreign makers of automobiles are taking and using American machine tools of the kind that have been developed in connection with the building of automobiles is sufficient proof of the keenness of the foreign makers, and it is not too much to state that keenness is the child of experience.

The only class of people who seem to be a little dull about the real status of the racing machine versus the stock automobile is the American purchasing public. It seems to have been the understanding of this public that the quality of an automobile is gauged on the scale of dollars, particularly if the name-plate on the car bears the cross of the collectors of the Port of New York. It will come as a surprise to those who have overlooked the underlying merit of standard methods of construction to find that American stock cars not only are capable of winning in a race like the Vanderbilt, but they finish in good shape.

The facts cannot be enlarged upon; the record speaks for itself. It is useless to try to emphasize the situation as it is. Perhaps a few of the underlying reasons will serve to clear the atmosphere and settle once for all the proper status of stock cars. The reason why special racing machines were conspicuous performers in the earlier events is due to the fact that the evolution of the stock car from its inception to its present state of perfection took five years in the consummation. Special cars, although they must ever rank as mere model work, had the advantage of much attention on the part of men who were more or less skilled and experienced in work of this character, and they rendered many a good service to the automobile business because they tried out a great number of ideas, all of which, in so far as they possessed merit, were incorporated into the stock cars, forming a part of the very evolution that ultimately resulted in the supremacy of the stock car and the downfall of the specialized product.

All Eyes on Grand Prize

MOTORDOM TURNS FROM VANDERBILT CUP RACE TO THE BIG CONTEST FOR UNLIMITED MOTORS WHICH WILL BE HELD OCTOBER 15

ENTIRELY different in its conditions from any other road race in the United States this year is the Grand Prize contest for the $5,000 gold challenge cup of the Automobile Club of America, which will be held on the Vanderbilt Cup course October 15. The only limitations placed upon the contestants are as to width, which must not exceed 68.89 inches; exhaust, which must not be directed toward the ground and each car which must not be directed toward the ground, and each car cars must be examined by the Technical committee prior to practice and must secure certificates showing that they are safe. The cars are required to carry two persons seated side by side, weighing at least 134 pounds each on the average. No agent of oxidation other than atmospheric air is to be allowed.

Under such a system of rules, the contesting cars may be simon-pure racing machines with special motors and special refinements of construction and equipped with any sort of device to assist mechanical operation that is deemed to be advantageous. On the other hand, stock cars with racing equipment are not barred. There is no limit on the size of engine to be used. Automobiles with nine-inch cylinders are eligible, just as are those of half that diameter.

The original intention was to have the distance of the race 22 laps on the 12.64 miles course, but later it was decided to increase the length of the run to 30 laps, which makes the distance 379.2 miles.

The start will be at daybreak, just as it was in the Vanderbilt, but owing to the moderate sized field, the intervals at which the contestants will be sent away will be 30 seconds.

The entry list this year consists of four trios and three single entries. Under the rules, each car must represent a member of the International Association of Recognized Automobile Clubs and while three countries are represented, only two clubs have been certified.

The Kaiserlicher Automobile Club of Berlin is represented by three Benz cars, while the other dozen in the list are credited to the Automobile Club of America. This classification is broader than it really should be, as the Fiat trio, Italian cars of much class, are included among those which will carry the colors of the American club and the same may be said for the Mercedes, entered by George W. Loft.

The sure-enough American cars that are carded to start are three Marmons, three Marquette-Buicks, an Alco and a special Roebling-Planche. Thus there are four German cars; three Italian and eight Americans in the race.

The drivers engaged to participate in the race represent the highest types of automobile pilots developd both here and in Europe. The contest will hardly prove to be as much of a drivers' race as the Vanderbilt Cup. The result will not be so strictly chargeable to good or bad driving as was the great contest of October 1.

The reason for this is two-fold: First, the field is only one-third the size of the Vanderbilt and second, there are no weak spots in the entire list of drivers. In other words, no matter how the race results, the outcome probably would not be changed if the driver of any of the losing cars had been seated behind the wheel of the automobile that finishes first.

Every man can be relied upon to get the uttermost atom of speed from his charge, as all are past-masters of the driving art.

From the viewpoint of actual money prizes, the Grand Prize is the richest in America. The Motor Cups Holding Company has hung up $7,000 for the winner and placed cars and while only $1,000 in supplementary and accessory prizes has been offered so far, before the day of the race dawns, the list will undoubtedly be largely augmented, and may reach $10,000.

The race October 15 is the second that has been held for the magnificent trophy and purses. The former run-off was held at Savannah, Ga., Thanksgiving Day, 1908, and the money prizes for that event approximated $20,000.

There were twenty starters, fourteen of which were the cream of European workmanship, guided by the best talent available. There were six American cars in the contest, but they were outclassed by the foreigners. The race was won by a Fiat, driven by Louis Wagner, who will also conduct another Fiat in the coming race. His win was spectacular and sensational in the extreme and was largely due to an element of racing luck in the final round.

The winning Fiat, a Benz driven by Hemery and another Fiat, driven by Nazzaro, had been running neck-and-neck since passing the middle ground of the course. For the last eight laps these cars alternated in the lead, and upon entering the final round Nazzaro's Fiat had established what seemed a winning margin over the Benz racer. Wagner's Fiat was in third place, about two minutes behind the leader.

While in full flight after passing the stand, Nazzaro suffered a puncture and time spent in repairs wiped out his lead. Then another puncture intervened and his chances for first place went winning. Wagner, without suffering any mishaps, swung over the line 56 seconds ahead of the Benz, while the unfortunate Nazzaro was third.

In the coming race this trio will have mounts from the same makers as they drove in the former race and a terrific struggle between them is promised, no matter where they finish. The roughness of the course must of necessity place a limit on speed. It is unlikely that many measured miles will be run at a 100-mile an hour gait, not because the cars are not fully capable of such speed, but by reason of the minute ruts and ripples on the racing surface. In the Savannah race a Renault car went slightly faster than 101 miles an hour for a single mile and one of the other contestants made an even 100-mile rate for a short distance. The straightaways, however, on the Southern course were longer than any on the Vanderbilt raceway.

At an average speed of 70 miles an hour, which does not seem a wildly unlikely speed, the American cars have shown that they are capable of maintaining that pace. Many miles have been timed in practice close to the 70 mark and rounds of the course in about 10 minutes have been common enough both in practice and in the Vanderbilt Cup race. An average round of 10:50, carried throughout the thirty laps, would be at a rate of 70 miles an hour and such speed is promised in practically all the camps.

The entries for the race are as follows:

Car.	Entrant	Driver
Benz	Benz & Co.	Barney Oldfield
Benz	Benz & Co.	Victor Hemery
Benz	Benz & Co.	Franz Heim
Fiat	Fiat Auto Co.	Louis Wagner
Fiat	Fiat Auto Co.	Ralph De Palma
Fiat	Fiat Auto Co.	Felice Nazzaro
Marmon	Nordyke-Marmon Co.	Ray Harroun
Marmon	Nordyke-Marmon Co.	Joseph Dawson
Marmon	Nordyke-Marmon Co.	....
Marquette-Buick	Marquette Motor Co.	Louis Chevrolet
Marquette-Buick	Marquette Motor Co.	Robert Burman
Marquette-Buick	Marquette Motor Co.	Arthur Chevrolet
Roebling-Planche	W. A. Roebling, 2d	W. A. Roebling, 2d
Alco	Am. Locomotive Co.	Harry F. Grant
Mercedes	George W. Loft	George H. Armstrong

The dark horse of the race is the Roebling-Planche entry which will be driven by Washington Roebling 2d. All the others are familiar racers. Mr. Roebling is an experienced driver and the word has been passed around that he expects to give a good account of himself in the contest.

French Commercial Test

MASTER BUILDERS OF PARIS TRY OUT VARIOUS TRUCKS WITH THE VIEW OF DETERMINING ECONOMY AS COMPARED WITH HORSES

INTERESTING official figures on the cost of automobile transportation for the building trade have been secured as the result of a month's test held jointly by the Automobile Club of France and the master builders of Paris and district. Believing that economies could be effected by using motors in place of horses, but not having the necessary technical knowledge to work out a scheme of motor transportation, the Master Builders' Association appealed to the technical committee of the French Automobile Club. This latter body arranged with eight automobile constructors to supply one truck each, and to submit to a rigorous control in order that accurate figures on cost might be furnished the builders.

The work to be undertaken consisted in transporting stones, gravel, plaster and general building material from the Association's quarries and headquarters at Viry-Chatillon to the site of building operations at Villejuif. The journey was one of 10.2 miles, over moderately good roads; the estimated speed was 6.2 miles for the outward trip under load and 8½ miles for the return journey empty. The load to be carried varied from 3¾ to 5¼ tons, but the method of payment was made according to square meter of material (stones, gravel, sand, etc.) and not according to weight, a single journey with a full load being paid at the rate of $3 to $4. Theoretically a square meter of any given material from one quarry ought to be practically invariable in weight, but it was found that the density of the material to be transported showed such differences that weighing had to be resorted to.

The tests showed that the precentage of time during which the vehicles were held up for repairs was 13 per cent. of the actual working time. Although it is obviously desirable to reduce this figure as low as possible, the technical committee considered it satisfactory, for the Paris General Omnibus Company estimates 20 per cent. of the running time for repairs and renewals. Working 9½ hours a day, traveling 62 miles, and maintaining an average speed of 6½ miles an hour, the average consumption of the eight vehicles was 13.2 gallons of gasoline, 1.1 gallons of lubricating oil, and ¼ pound of grease per day, the cost being, in round figures, $4 per day for fuel. In making comparisons it must be remembered that gasoline costs practically 42 cents a gallon outside Paris. As a basis for this class of work it was established that for 5-ton loads a motor of 25 to 30 horsepower should be employed; cost of fuel should be calculated at $4 to $5 a day; repairs and renewals should be calculated at the rate of $5 to $6 a day, the fuel consumption should not exceed 14 gallons, and the range of action should be about 60 miles a day. These figures are based on trucks with metal-shod wheels; if solid rubber tires are employed the cost is estimated to be increased by 3 cents a ton-kilometer. It should be noted, too, that for this class of work every full journey was followed by one of equal length without load, and that the distance being comparatively short, much time was spent in loading and unloading. Had it been possible to give the trucks a load for the return journey a considerable economy could have been effected.

The trucks submitted varied considerably, as will be seen from the following table setting forth their characteristics. They had all internal-combustion motors, and all chain drive, with the exception of the Krieger, which had electric transmission and drive. Metal tires were employed by all but the Dietrich and Krieger. Three of the competitors used tip bodies, the other five having the fixed type. The width of the bodies averaged 40 inches, but the length varied from 13 feet to 23 feet; the weight of the body alone averaged 1,110 pounds. Delahaye, Krieger and S. T. I. M. used gasoline as fuel; Dietrich employed white spirit; Soller and Aries employed benzol, and Schneider and Dufour used successively gasoline, alcohol and benzol.

Make	H.P.	Bore Ins.	Stroke Ins.	No. Cyl.	Cooling	Quantity Water	Weight Empty, lbs.
Dietrich	27	4	6.2	4	Pump	8.8	7,275
S.T.I.M.	25	4.3	5.5	4	Pump	17.6	10,000
Soller	24	8.2	6.2	2	Pump	22	9,259
Aries	30	5.1	5.1	4	Pump	6.6	.....
Schneider	40	4.8	5.5	4	Thermo	7.2	11,000
Krieger	24	3.5	4.7	4	Thermo	8.8	5,467
Dufour	20	7	6.2	2	Pump	15.4	7,495
Delahaye	30	3.9	7	4	Pump	9.9	7,275

Ignoring the amounts spent on the vehicles for repairs, the most satisfactory performances were made by the Delahaye, Schneider, Soller and Aries trucks. The following table shows the distance covered both under load and empty, the time spent in useful work, the consumption of gasoline and lubricating oil and the average speed maintained. Under this latter head is given the average under load and empty, the difference between the two being very slight.

Truck	Distance covered Total	Load	Empty	Time, hrs.	Speed av'r'ge	Av. Daily Consumption Oil	G's'l'ne	Average useful load, lbs.
Dietrich .	1,481	739	742	186.3	7.5	2.1	14	8,099
S.T.I.M. .	1,114	556	558	216	6.4	1.7	12.3	8,886
Soller	1,525	761	764	270.2	6.9	0.75	14.7	11,772
Aries	991	495	496	185	6.5	0.95	14.0	11,772
Schneider.	703	351	352	119.2	7.3	0.81	13.1	11,862
Krieger ..	844	424	420	145	6.9	0.67	11.2	8,677
Dufour ...	...	...	...	...	...	....	....	.....
Delahaye .	1,481	739	742	255	7.2	0.38	10.8	9,347

Distance and speed limits in miles; oil and gasoline in gallons

---

Car versus Horse in Real Economy Test

In an effort to prove the much-discussed proposition that it is cheaper to drive and use an automobile than a horse and buggy, the Maxwell-Briscoe Motor Company is conducting a practical test in New York City and vicinity. This test consists of actually driving a horse drawing a buggy for six hours a day and a Maxwell automobile of current type, four-cylinder motor, for the same length of time.

Of course the automobile goes practically over twice as far as the horse in the course of the six hours run each day and the figures, in order to form the basis of any just comparison, must take that fact into consideration. The comparative cost per mile and cost per passenger per mile to operate both systems of transportation have been worked out in detail as far as the test has progressed.

All the suburban districts of New York as well as the heavy traffic streets of the metropolis have been or will be covered.

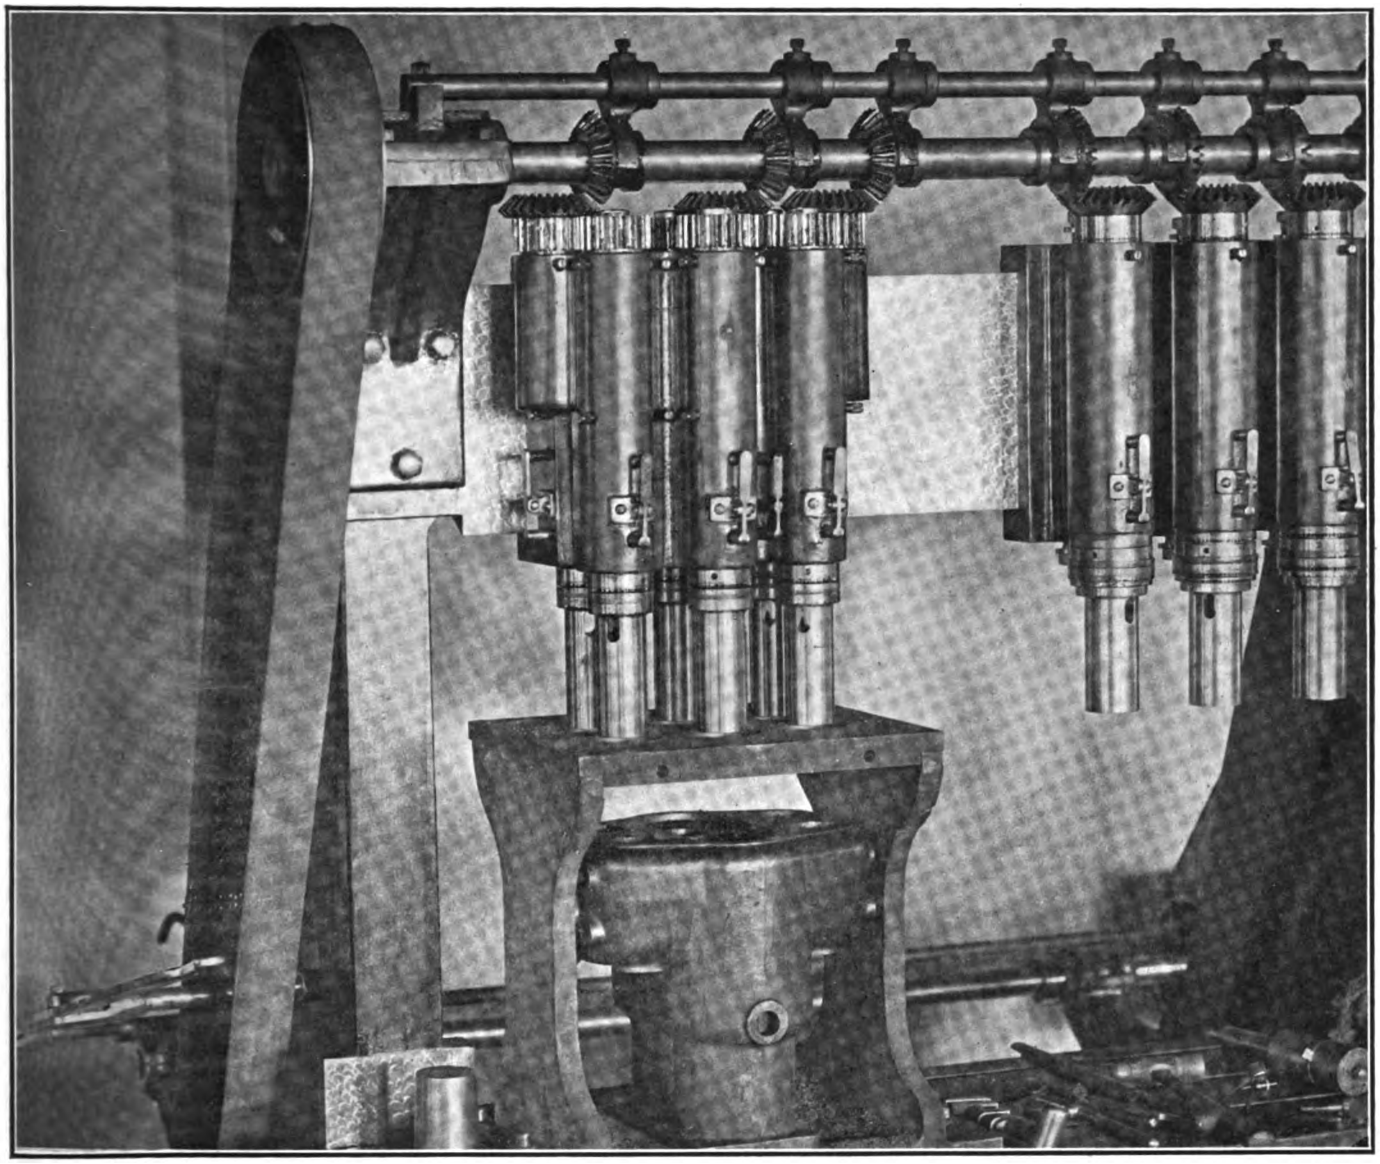
One day's run is typical of the rest as far as the figures are concerned. Take the fourth day for example. The route was laid out through Staten Island and the interesting contest started at 9 o'clock in the morning. The horse and buggy were first away, but the car soon established a big lead and was only in sight of the horse when doubling on its trail.

During the six hours the car covered 80 miles without any mechanical repairs, replacements or adjustments. The motor consumed 5 3-4 gallons of gasoline, which cost at retail 16 cents a gallon or 92 cents. It also used one pint of lubricating oil at 65 cents a gallon or 8 cents. This made the total $1 even for the day.

The horse traveled 35.8 miles during the six hours and required 12 quarts of oats at 6 1-4 cents per quart or 75 cents and 20 pounds of hay at 1 cent per pound or 20 cents. This made the total expenditure for the horse 95 cents for the day. But the horse traveled only 35.8 miles on 95 cents, while the car made 80 miles on $1.

Among the Makers

DETAILS OF THE RAMBLER FOR 1911—PULLMAN LINE FOR THE COMING YEAR WILL SHOW MANY REFINEMENTS—MECHANICAL POINTS OF THE SELDEN—ELMORE 1911 MODELS DISCUSSED



SPECIAL FORM OF MULTIPLE-SPINDLE DRILL USED AT THE MOON PLANT TO BORE CYLINDERS WITHOUT RESETTING

SPECTACULAR automobile building is passing into history and the time is arriving when the man who elects to go into the business of manufacturing automobiles will have to make a large investment for special machine tools of the class that will be capable of doing work on a par with the special forms of machinery that are now being employed in the plants where automobiles are really made. A cursory examination of the manufacturing proposition, considering it as a whole, lends substance to the conclusion that automobiles will have to be sold hereafter, and the man who buys is much inclined to find out what he is to get for his money. In the plants that are fitted out to build good automobiles in sufficient quantity to control the "overhead" charges, despite an enormous investment in special machine tools, there will be no difficulty in convincing the man who buys that he will be justified in making the investment, but the influence of special equipment will be felt by makers in one of two ways, *i.e.*, (a) the maker who is so fortunate as to have the special equipment will be able to turn out a large number of good automobiles at a low price, (b) the maker who cannot afford to manufacture on a specialized basis will have to devise some way to back out of a critical situation. Prospects in the commercial automobile field are regarded as sufficiently good by some makers of passenger automobiles as to serve as the reserve position if a turning movement becomes necessary. This is all very consoling, but if all the makers of passenger automobiles turn their attention to the manufacture of freight automobiles, provided they move simultaneously, the supply of freight automobiles will far exceed the demand.

Rambler Line for 1911

TWO CHASSIS AND NINE SEPARATE STYLES ARE OFFERED FOR THE COMING YEAR—DETACHABLE FORE-DOORS AND NUMEROUS REFINEMENTS WILL FEATURE THE OUTPUT

THE Rambler for 1911 offers a complete line, including open and closed cars in nine different styles, all with detachable fore doors. The details and mechanical construction of all are alike and there are two sizes—45 and 34 horsepower. The fundamental Rambler advantages characteristic of previous models, the offset crankshaft, straight-line drive, large wheels and tires, spare wheel and engine accessibility, are all continued.

Improvement has been made chiefly in details which have been thoroughly refined. Standard equipment for all 1911 models include spare wheel and tire, Hartford-Truffault shock absorbers, top and envelope, wind shield, gas headlights and Prest-O-Lite tank, combination electric and oil side and tail lamps.

The 45-horsepower chassis is used for Ramblers Sixty-four and Sixty-five. Sixty-four may be had as a five-passenger touring car, toy tonneau or landaulet; Sixty-five as a seven-passenger touring car or seven-passenger limousine.

Sixty-five has 128-inch wheelbase, 40 inch wheels and 4 1-2 inch tires, underslung front springs and drop frame. The two features last mentioned are to provide a low body level and this model, with 40-inch wheels and the increased clearance, has the same body level as the five-passenger model with 36-inch wheels. It is particularly pointed out that with the advantages of clearance, riding qualities, appearance and less tire wear provided by the larger wheels and tires, the increase in tire cost over the 36 x 4 1-2 size is but $10 per tire. The standard finish for Sixty-five includes nickel trimmings. This change from common practice with 40-inch wheels gives to this model added character and individuality.

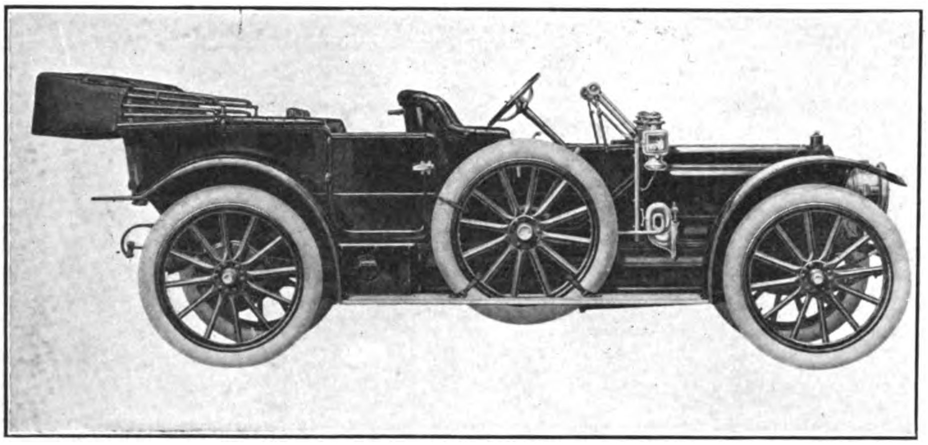
Rambler Sixty-four, in other details like Sixty-five, has 120-inch wheelbase, 36-inch wheels, 4 1-2 inch tires and regular front spring suspension with straight frame and brass trimmings.

The 34-horsepower car, known as Sixty-three, is furnished as a five-passenger touring car, two-passenger roadster, four-passenger coupé and town car. This is a more economical car to use and maintain and is particularly popular with the owner who prefers to drive his own car.

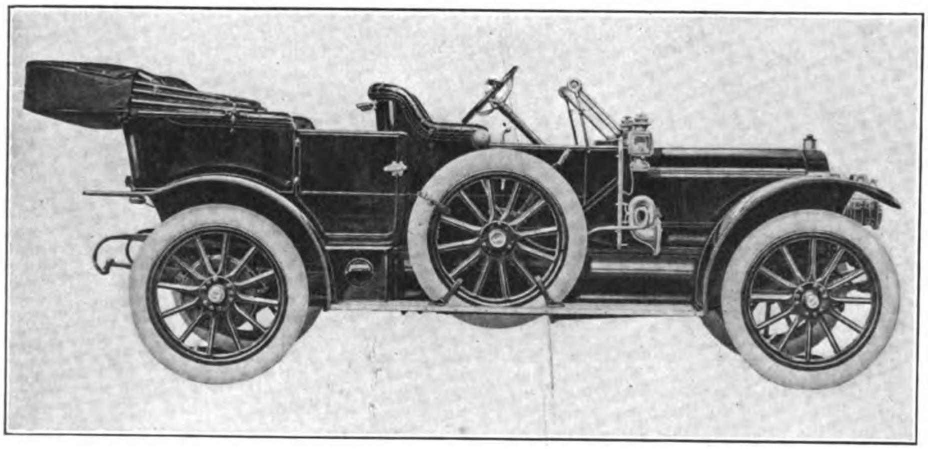
The Roadster is regularly geared to a speed of from 55 to 60 miles. For a hilly locality a lower gear, giving greater hill climbing ability is optional.

Sixty-three has 112-inch wheelbase, 36-inch wheels and 4-inch tires. This model is furnished with dual ignition, Splitdorf magneto and 6-80 Vesta storage battery.

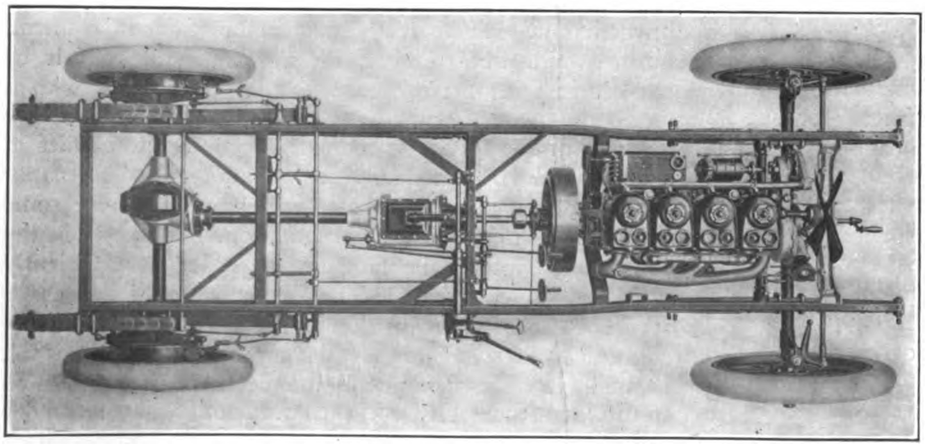
The 45-horsepower models have double ignition, Bosch magneto and 6-80 storage battery. Both sets, by means of the Rambler high-tension switch and the Rambler timer, operate through a single set of plugs.



Model 55 complete with top, top cover, glass front and spare wheel



Model 63 presenting the right side of the car with the spare wheel on the running board



Model 64 chassis, showing brake adjustment by means of thumb nuts and larger brakes

Sixty-three body is trimmed with a good quality of machine-buffed leather and the larger models with hand-buffed quality. Excepting these two particulars, magneto and leather, the quality and details of all models are identical.

The improvements which are found in these 1911 models are as follows: The fore doors for all models are practically dash high, but are detachable. Anticipating a desire by owners to remove the doors in hot weather, new models have been designed so that they may be used and look equally well whether with or without the doors. To accomplish this interchangeable feature, the front floor and floor supporting brackets have been redesigned. The sloping section of the floor now has a greater angle with, of course, corresponding increase in comfort as a foot rest and the side brackets are flush with the floor level.

On earlier models these side brackets were higher. On the lever side a solid panel, a duplicate of the door on the left side, extends from the seat to the dash with transmission lever inside and brake lever in a convenient location outside. The latch for the left side door is secured to very neat aluminum door jamb fastened to the seat riser. The photographs illustrating the appearance with and without the doors.

The standard form of front springs, semi-elliptic, is continued, but these springs are now wider and thinner, providing greater flexibility. One of the most important changes is found at the rear springs. These are called 7-8 elliptic, differing from the common type of 3-4 elliptic spring in that the upper section is longer and is secured at two points instead of one. By passing two spring bars through the frame from one spring to the other and securing the springs to these bars, the frame is relieved of practically all twisting strain and side sway is effectually minimized. Grease cups are now equipped at every spring joint.

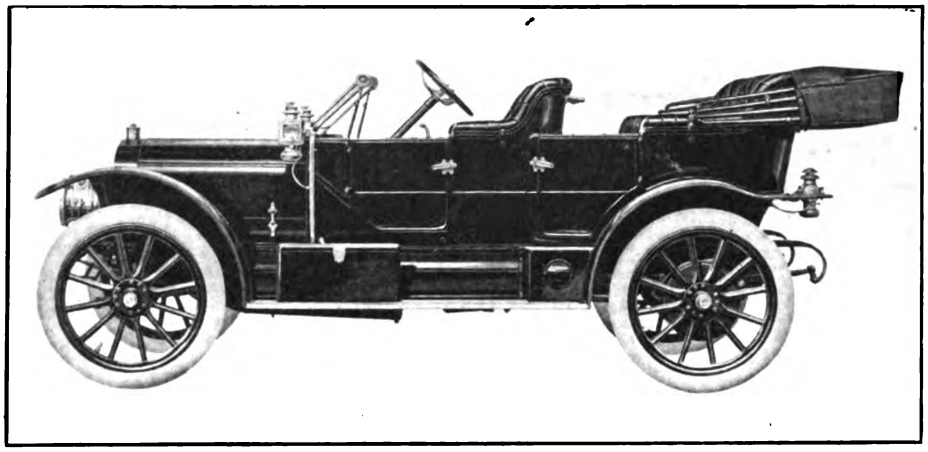
In conjunction with the new springs, Hartford-Truffault shock absorbers are included as standard equipment. Four are furnished for the 45-horsepower chassis and two for the 34-horsepower chassis.

The brakes are larger and the leverage greatly increased. The wheels may be locked by the application of either set and every car is required by test to come to a full stop from a speed of 18 miles an hour within 50 feet. The brake drums are increased in diameter from 13 to 15 inches. In width the braking surface is increased from 2 to 2 3-4 inches, the total increase in surface being 97 square inches. The foot brake is connected to the outer band, the band being contracted by lever action giving a greatly multiplied force over the previous design.

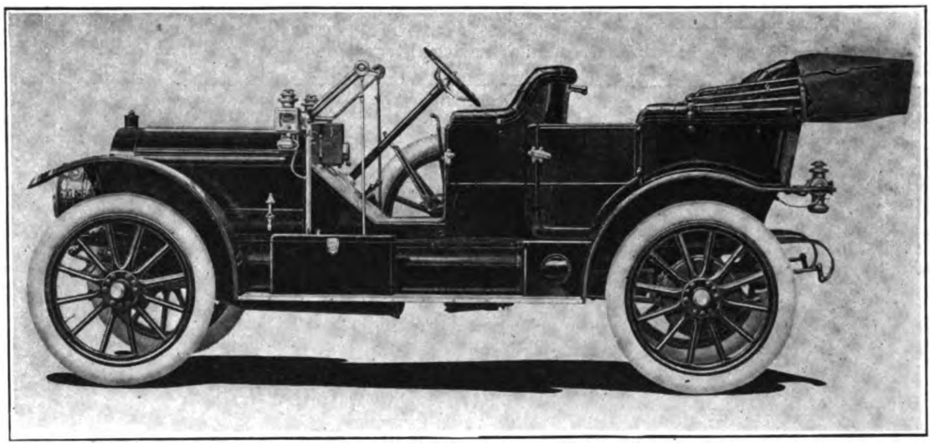
The inner expanding shoes are operated on the toggle joint principle. The application of both sets of brakes is shown by the illustrations. Both brakes are provided with equalizers. Spokes for 36-inch wheels are increased in width from 1 1-2 to 1 3-4 inches and are 2 inches wide for the 40-inch wheels.

The Stromberg carbureter has been adopted for 1911 and it is located on the right instead of on the left side. This change principally facilitates starting in cold weather. The inlet manifold is carried above the exhaust and two priming plugs are placed on the top in an accessible position. If at any time difficulty is experienced in starting, raw gasoline may be inserted by removing these priming plugs.

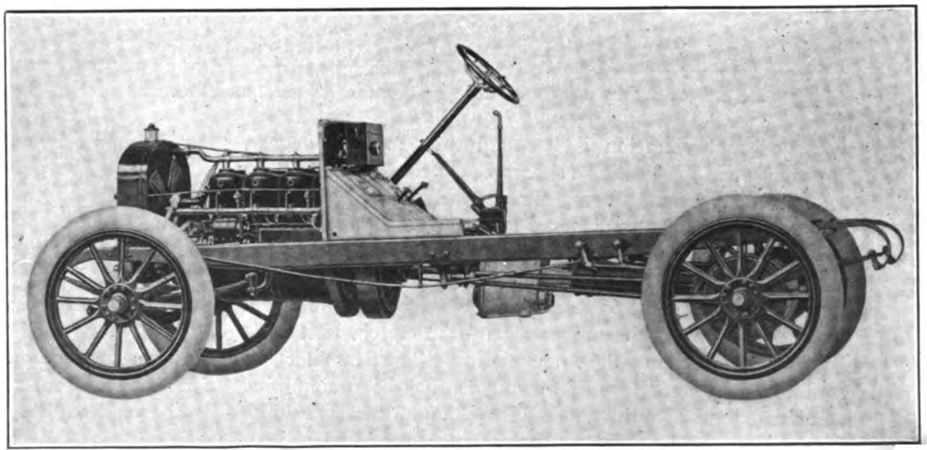
The cams and camshaft are now forged integral. The cams are alike and uniformity in this particular is absolutely assured in every motor. The magneto coupling is now bolted together. This facilitates removal of the magneto and change of timing. The lubricator, formerly supported in a bracket attached to the frame, is now secured to the engine. The oil feed pipes are



Rambler 63, including top, top cover, glass wind shield, spare wheel, tire, lamps and tools



Model 63, showing car with fore-door detached for hot weather



Model 64 chassis, side view, showing new aluminum floor design

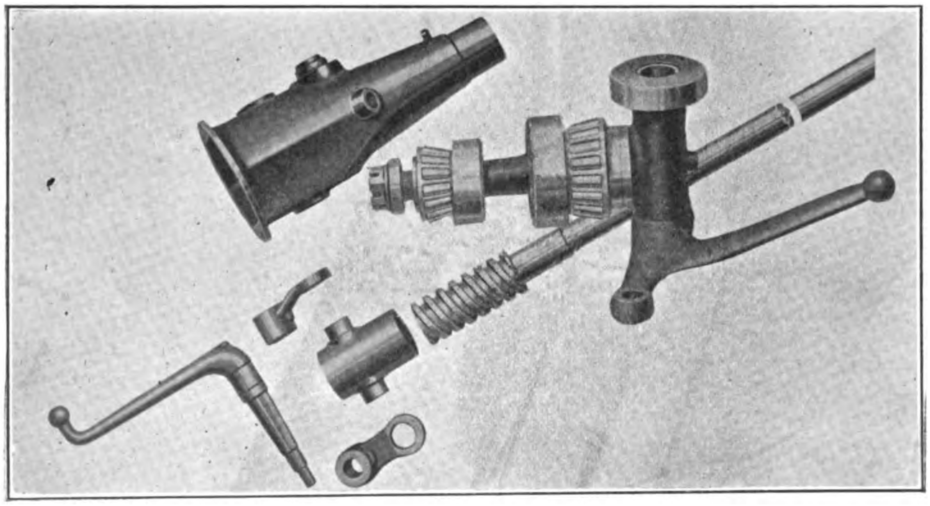
Model 64, crankshaft and camshaft, with integral cams properly hardened



Details of front wheel knuckle and parts as used in steering

thus shortened and vibration is lessened to a marked degree.

The ignition wiring is partially encased. On the 45-horsepower chassis the crankshaft and bearing surface is increased 28 square inches. The flywheel is bolted instead of beyed to the crankshaft. Although of the same weight as before, the metal in the flywheel is diffrently distributed to give greater weight at the rim.

The universal joint shaft is longer. The increase is sufficient to permit the removal of the universal and the clutch, if it is so desired, without disturbing the transmission. The Rambler expanding clutch, now a feature of all models, has been simplified both in construction and adjustment. The change does away with the separate shoes and separate toggles with individual adjustments provides a single expanding shoe, thus giving equal pressure at all points and contact throughout most of the entire circumference. One simple adjustment of the toggle joint makes all necessary changes.

The transmission gears are heavier, being 3-16 inch wider. A lock is placed on the second gear to hold it in engagement. Taper roller bearings are substituted for ball-bearings at the rear axle differential. This is also true of the wheel bearings on the front steering knuckles for the 45-horsepower chassis.

The radius or distance rods, previously used on all Ramblers, are replaced by a combined distance and torsion rod. At the axle end these rods are secured to a forged bracket above and below the axle, rigidly holding the axle in place and relieving the drive-shaft housing of torsional strain. At the other end these torsion rods are secured in ball and socket joints to brackets bolted to the frame side members. Heretofore the brackets for the forward end of the radius rods were bolted to a cross frame member. The change gives increased rigidity. The re-enforcement in the tubular front axle for the 45-horsepower models is treble its former thickness, giving proportionately greater strength.

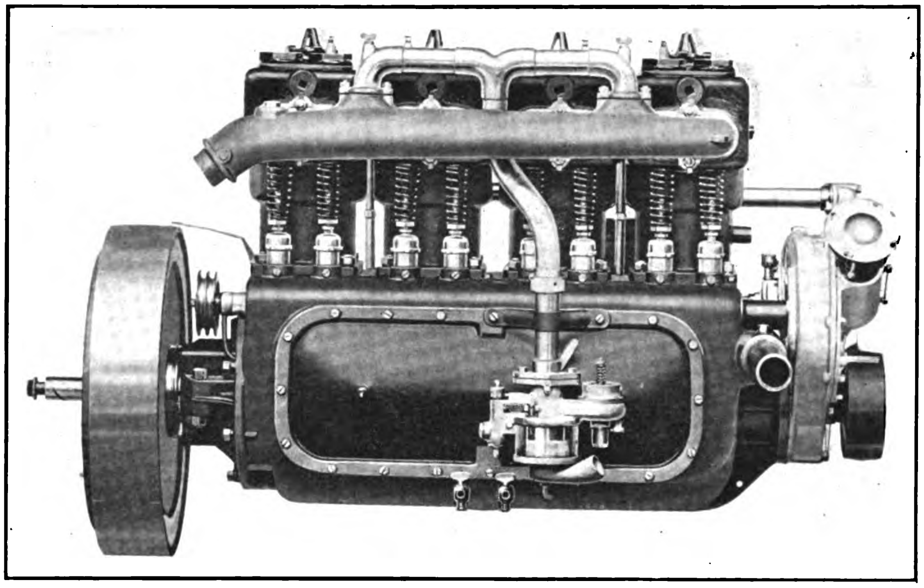
The knuckle pin for the larger chassis is secured in the steering knuckle to prevent wear between knuckle and pin. Hardened and ground bearings are placed in the knuckle yoke and the pin is hardened and ground at the point of contact with these bearings. The wear is divided between these bushings and the ball thrust bearing on top of the knuckle.

The appearance of the car viewed from the front is quite materially changed. The radiator is supported on an aluminum girder of new and neat design, well harmonizing with the other parts. The brass corners of the radiator, formerly polished, are now japanned and the crown sheet which extended forward from the radiator is now finished with a heavy roll flush with the radiator. Brackets containing sockets for the front guard braces, located at the side of the radiator and on top of the frame side members, gracefully complete the finished effect.

The screw and nut principle for steering is continued, the nut being somewhat longer to give greater wearing surface and the steering parts in general are slightly heavier and stronger. The guards are carefully shaped to obtain the most harmonious appearance. The guard fillers extend to the top of the frame, entirely covering the running board supports. These fillers are secured to the frame by acorn nuts and bound at the running board edge by an aluminum strip. An aluminum toe guard protects the filler on the forward left side.

The interior of every tonneau is completely trimmed with leather; commodious pockets are attached to the doors; the surface of the front seat back, usually varnished, is protected by a leather pad and the space below is utilized as a pocket for the top side curtains. Seat backs of Rambler Sixty-five are higher.

The headlights on the 45-horsepower chasses are one size larger than last year, being 8- and 9-inch sizes for the five- and seven-passenger models. These and the side lamps are placed higher, adding to the appearance and affording better light. Side and tail lamps for all models are combination electric and oil. The current of these lamps is furnished by 6-80 storage battery and they are operated by a three-point push switch.



Model 64 and 65 engine, showing new carbureter and location, new intake pipe with priming plugs over intake valves

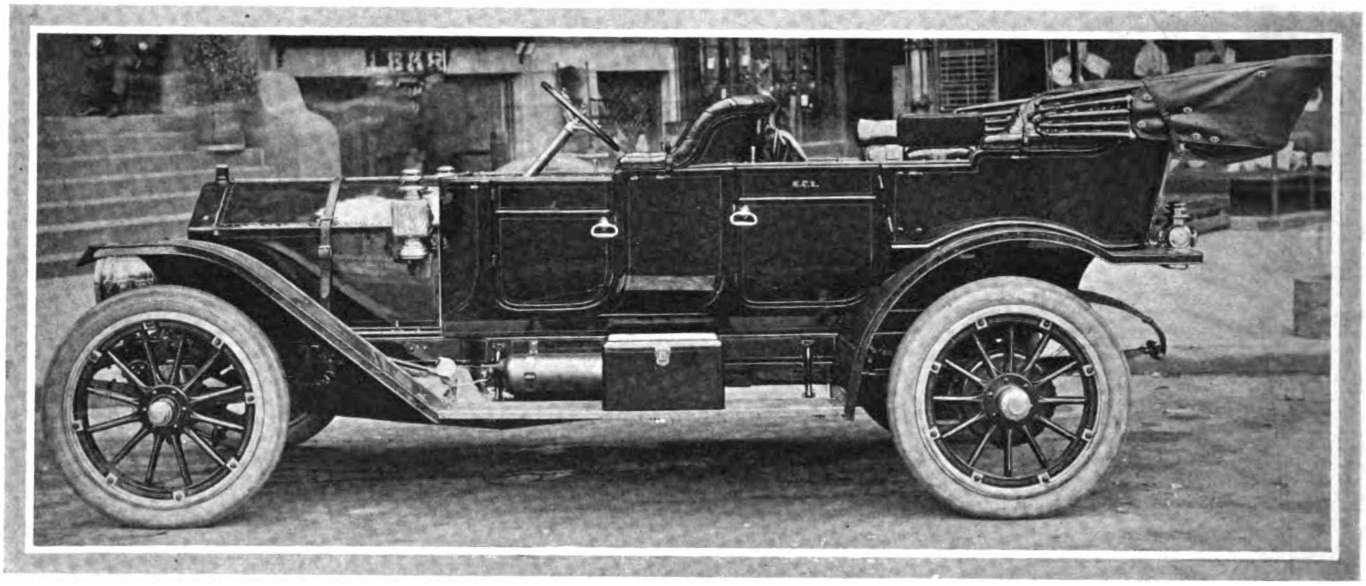
Methods of Testing

The final completion of the laboratory, some of the details of which were described in THE AUTOMOBILE some time ago, consummated the plan that assures detailed and exact testing of every Rambler car manufactured in addition to a proper investigation of the units of each automobile before they are assembled into the respective cars. This laboratory situation is of far-reaching importance. It may not be generally understood that the testing out of a considerable number of automobiles every day demands the use of a vast amount of equipment, and a large number of skilled men, under ordinary conditions, the cost of which becomes so great that it is something of a question as to whether or not this part of automobile building, taking it in general, has been afforded the care and attention it naturally deserves.

The new laboratory in the Rambler plant possesses several innovations that are labor-saving, hence the more accurate, it being the case that the "personal equation" is the most to be feared in any test room. It is not impossible to find here and there a skilled man who will do good and accurate work every day, but it is substantially impossible to rely upon the skill, judgment, and reliability of a plurality of men. In the Rambler test room every motor is brought in and put down on a stand, there being enough of these stands to handle the daily output of the plant with sufficient promptness to prevent a slow-down in the regular shop work while tests are being made. The test stands are provided with electric motors, one for each, which motors are so designed and connected up that they will run either as dynamos delivering current for storage batteries, or as motors deriving electrical energy from the same storage battery, in which event the motors drive the gas engines to be tested.

As each motor is delivered to its test stand it is profusely lubricated, and the electric motor is connected up to a tumble shaft, all of which is done in a moment, and the motor to be tested is driven by the electric motor until the electrical instruments employed for measuring show that the friction of the motor to be tested is down to its proper level. After this, the motor to be tested is made the driving unit, and the electric motor is turned into a dynamo by means of which the motor to be tested is loaded and the current delivered from the dynamo is passed through measuring instruments for the purpose of determinating the amount of a load. The electric energy thus generated by the motors undergoing the test is utilized to charge the storage battery, and in this way every motor that is tested is put through its paces speedily; moreover, the actual waste of energy in the whole system is limited to that which is dissipated by friction and heat losses.

Each motor, before it is permitted to do any work at all, must show on the electrical instruments that the friction losses, internal within itself, are down to a certain standard; it must also be shown that the motor is in a good state of kinetic balance, and the performance of the mechanisms must be noiseless with entire freedom from gas leaks and other recognized indications of poor mechanical work. As the motors come off the test stand they are checked up as to timing and thermic performance generally; in this class of testing the manograph is employed as the sole guide, it being understood that it is utterly impossible to reach a conclusion of any worth from the thermic point of view without employing the manograph. It was found, after some experience, that the ordinary forms of manograph, while they evolved a certain amount of accuracy, were far too slow.



Model M 1911. Fore-door type of touring car, seating seven passengers, showing a well-fitted top folded down, and other advanced features

Pullman 1911 Announcement

TWO INCHES ADDED TO THE WHEELBASE OF ALL MODELS; MATERIALS USED ARE MUCH REFINED.

SO entirely satisfied is the Pullman Motor Car Company, of York, Pa., that its 1910 product was close to perfection that in the output for 1911 will be incorporated only those minor mechanical changes and refinements in design which the natural progress of a year would seem to demand. The numerous road and track successes of the Pullman during the past year would seem to warrant this course.

As was the case in 1910, the 1911 list will include Models K, O, and M—Model K registering 32.4 horsepower (A. L. A. M.); Model O, 26 horsepower, and Model M, 44.1 horsepower. Of Model K there will be three body models—touring car, seating seven; roadster, three, and toy tonneau, four. There will be the same number and types of body designs of the O model—seating four, three and two, respectively. Model M will be represented by a touring car with a capacity of seven and a toy tonneau seating two. The upholstery is luxurious, hand-buffed leather is used, and comfort is looked to with care and precision.

In the matter of wheelbase length, all three models have been added to to the extent of 2 inches as compared with last year—K to 114 inches, O to 110 and M to 126. The tread has been reduced in all three models 1-2 inch to 56 inches.

Information in Relation to Model K 1911 Motor

This motor is shown in two views, Fig. A being the left-hand side and Fig. B being the right-hand side. Referring to Fig. A, the magneto M1 rests on a shelf S1 in front of the arm A1. The magneto is driven from the shaft S2, which extends out of the half-time gear box B1, but the water pump W1 intervenes and takes its power from the same shaft. Both the magneto and the water pump are flexibly mounted, and Oldham joints J1 and J2 are utilized to bring about the condition of flexibility desired and to compensate for minute differences in alignment, it being the case that absolute accuracy cannot even be found in a chronometer. The water pump has a drain cock D1 at the lowest point in the water system, and the water intake passes up to an enlargement around the shaft, while the water manifold M2 flanges off of an extension from the pump in the upward direction, leading the water into the cylinders at a point just under the exhaust manifold E1. Attention is called to the accessibility of the exhaust manifold flange bolts B2, of which there are two for each leg. The cylinders C1, C2, C3 and C4 are cast individual of the T-type, bringing the inlet and exhaust valves on opposite sides, but there is one point which should not be overlooked in scanning the scenery of this motor; the cylinder jackets are cast open on adjacent sides, so that the respective cylinders are flanged F1 to each other, the two outside cylinders having covers C5 and C6. This school of design affords certain advantages. A trip to the foundry where the cylinders are cast, and a short study of the ramifications in the foundry, will lead up to knowledge of the fact that good, sound castings are only to be had if the gases are tapped away, and it is a recognized fact in foundry work that to be able to dispose of the gases it is necessary to provide an exit for them. When the water jackets are cast all around it is extremely difficult to keep the gases from shooting through the solidifying metal instead of passing around to the small holes that are left from core prints, etc. But by casting the cylinders in the manner as here shown a large opening is afforded on each side of each cylinder for the disposal of the gases that form, and bolting the cylinders to

each other in this way lends extra stability to the structure, nor can it be claimed that the cost or complication is increased at all.

Referring to Fig. B of the right-hand side of the motor, it shows the Stromberg carbureter C1 with its manifold M1 and an accommodation piece A1 intervening. This brings the carbureter on the side opposite to the magneto, which is as far away from the source of an ignition spark as it is possible to get. This view offers a chance to appreciate the accessibility of the timer T1, which is between the third and fourth cylinder and above them, taking power from the vertical shaft V1. Breathers B1 and B2 for the crankcase come up out of the arms through a tortuous passageway so that the lubricating oil within the crankcase is prevented from shooting out through the orifices of the breathers. The flywheel F1 is of sufficiently large diameter considering its face and the thickness of the rim to afford the fullest measure of "flywheel effect" without reaching into the danger zone from the point of view of extreme fiber strain in the rim section due to centrifugal force. The four cylinders of the motor, in view of the method of flanging, occupy the minimum space, and the motor is rated at 35 horsepower by the maker, the cylinders having a bore of 4 1-2 inches and a stroke of 4 3-4 inches. The magneto is a Bosch with a battery auxiliary, and lubrication is by means of a circulating pump. The cone clutch C2 shows nested in the flywheel, and the actuating mechanism, including the clutch spring, are within the housing H1.

Lay-out of the Model K 1911 Chassis

In this view the radiator R1 is on the center line of the front axle A1, and the motor M1 occupies a position which brings the flywheel F1 at the point of narrowing N1 of the chassis frame. The universal joint U1 is between the motor and the transmission gear G1. The propeller shaft P1 is provided with universal joints U2 and U3, the latter being close to the live rear axle A2, and torsion is compensated for by a torsion rod T1, which is anchored to the cross-member C1 with a shackle S1. Both front and rear springs are of the half-elliptic type, and the rear springs S2 and S3 are unusually long with wide plates, thus inducing the fullest measure of flexibility, coupled with the proper snubbing function, so that the car rides with freedom from undue vertical bounce. The live rear axle is of symmetrical exterior, of great strength, but light, and by a study in straight-line design it was possible to make the links and levers controlling the brakes in the drums of the rear wheels straight and fair. The equalizer E1 for the service brake comes inside the chassis frame, and the rods for both the service and emergency brakes are dead straight, due to the use of extension pieces E2 and E3, which are flanged and bolted to the chassis frame at a point just in front of the front anchorage of the rear springs. The front axle is of the I-section, with stout knuckles and through pins, and the steering drag-rod D1 comes in a protected position above the axle, while the cross-rod C2 is straight and behind the front axle. There are other nice features of design that will be apparent to the reader upon inspecting the plan view.

Design of Model K 1911 Transmission Gear

This gear is of the three-speed and reverse selective type with flanges F1 and F2 on the sliding gear and final drive shafts, respectively. A universal joint is used between the transmission gear and the clutch, one member of which, U1, is shown, indicating a mating flange and the method of bolting. The sliding gear shaft S1 has integral flutings, and the sliding gears G1 and G2 are splined to match. The sliding gear G1 meshes with mating gears G3 and G4 on the lay-shaft S2, while the sliding gear G2 meshes with the gear G5 on the lay-shaft S2, and in the opposite direction a dog clutch D1 is brought into engagement, making the high-speed direct-drive. Motion is imparted to the lay-shaft S2 by means of the master gears G6 and G7. The sliding gears G1 and G2 are actuated by forks F3 and F4 and motion is imparted to these forks by means of the selector bars B1 and B2. The shafts float on Hess-Bright annular type ball bearings B3, B4, B5 and B6. The gears are six diametral pitch with wide faces and are turned from bars of chrome vanadium steel, after which they are hardened and subsequently heat-treated to impart kinetic qualities without destroying the hard shell. The prime and lay-shafts are of chrome vanadium steel also.

The fenders are rakish, made from pressed steel, with the running boards enclosed. Dashes are mahogany, brass bound.

The bodies are of wood and aluminum, upholstered in hand-buffed leather. The gasoline tank is located underneath the front seat. Each

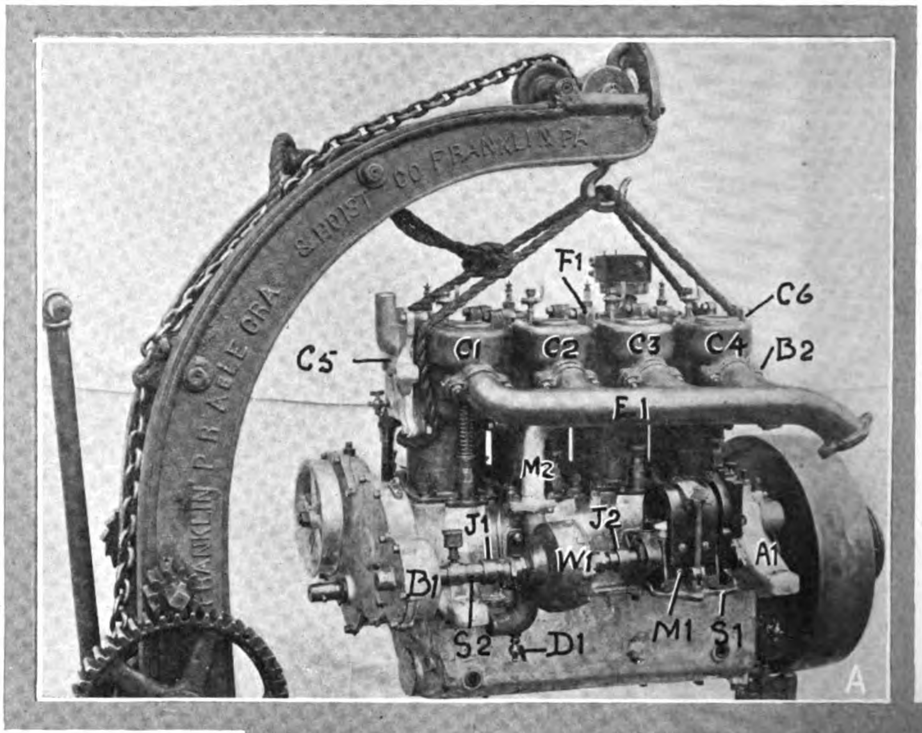
Model O 1911. Five-passenger touring car with an overhanging cowl, fitted with a top folded down, showing a roomy tonneau car comes equipped with two gas headlights, gas generator, two oil side lamps, an oil tail lamp, horn, tools, coat and foot rails.

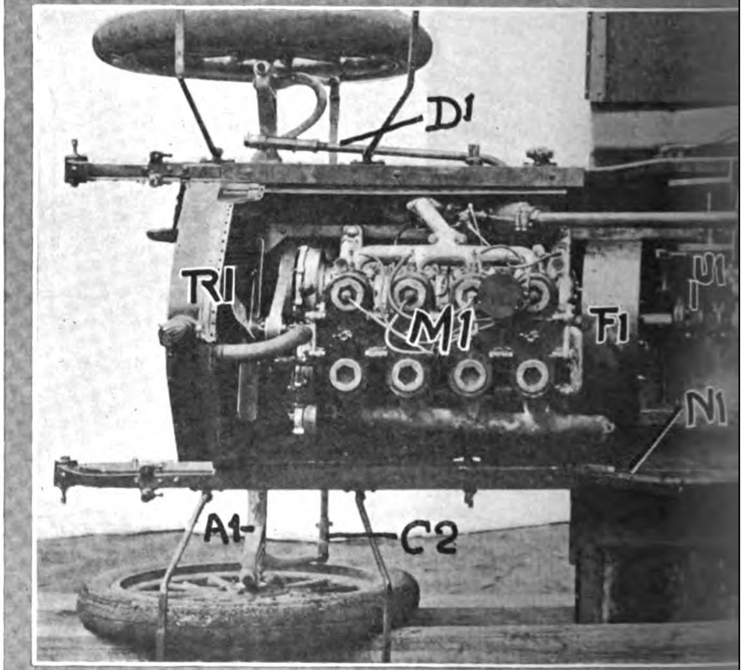
The standard color is "Pullman red," a very durable and distinctive shade. Dark blue with straw-colored wheels or black with wheels of similar tint are among the options.

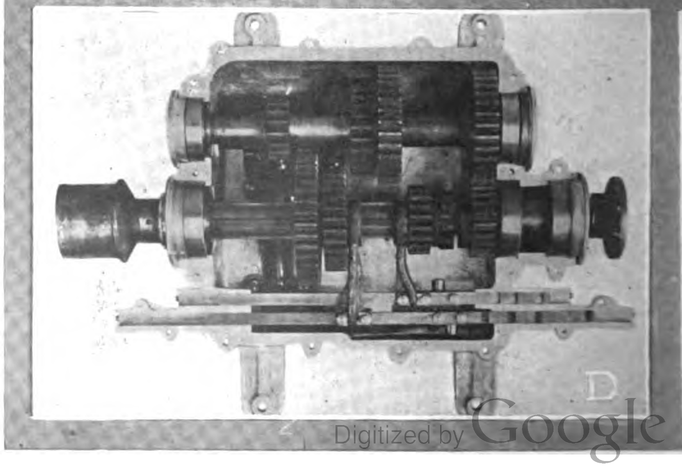
The tire equipment of Models K and O calls for 34 x 4 front and rear, the Model M cars being equipped with 36 x 4 1-2 front and rear.

From the price standpoint, the Pullman 1911 proposition is identically the same as that for 1910—$1,650 for Model O, $2,000 for Model K, and $3,500 for Model M.

The illustrations as presented on this and the following page, if subjected to a close examination, will disclose to the interested reader many points of mechanical refinement on a basis of harmony that were not fully disclosed by discussion, and it is pointed out that the motor as it is here shown is picked up by a system of travelers that indicate in a small measure the excellence of the equipment that is used at this plant in the manufacture of automobiles, moreover, it is fitting to state that the cars are very completely made by the company, rather than to be classed as a product that is assembled from parts that, for assembled automobiles, are purchased elsewhere.







Automobile Colors

By M. C. HILLICK

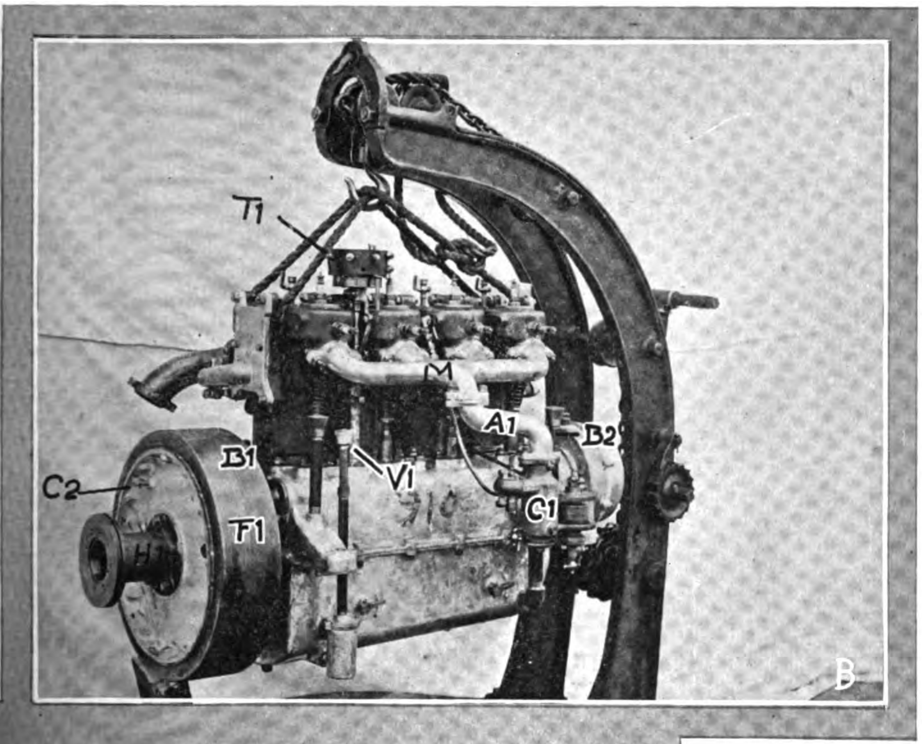
Doubtless the automobile owner as well as the automobile painter will be interested in the subject of popular colors for the season of 1911. With the march of the season, of course, will come not a few color novelties intended to appeal to a class of buyers intent upon securing decidedly unique or sensational pigment effects. The great majority of colors, however, destined to be in evidence upon the horseless carriage next year will be the colors that have found favor this year, or pigments closely related to them.

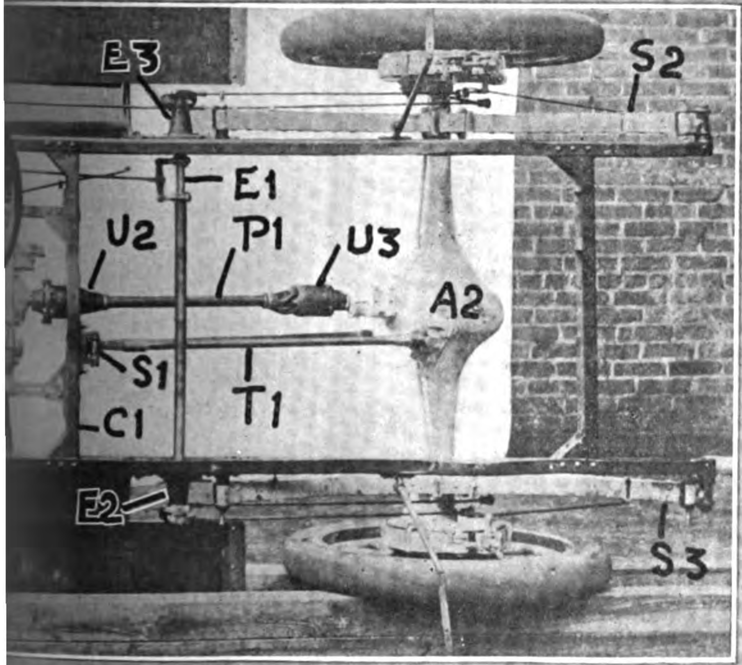
Among such colors the lakes must be reckoned with. The lakes comprise an interesting and numerous family of pigments, many of them rare and costly, and all of them charming in their wealth of color effects.

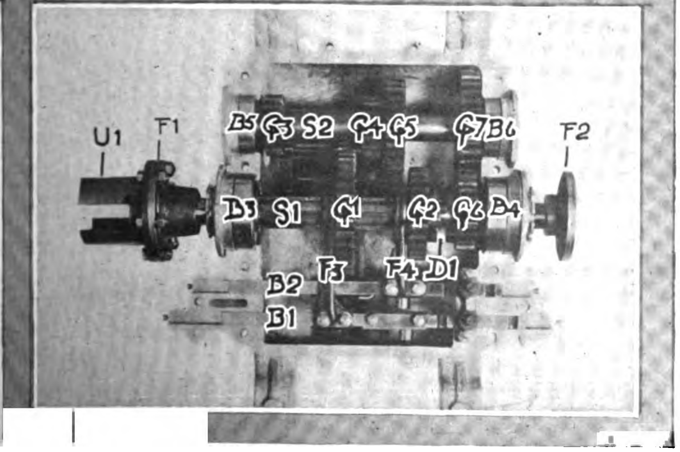
The principal lakes are maroon, crimson, Chatimuc, carmine, Munich, scarlet, mauve, madder and purple. As illustrating the extent to which many of these lakes are now being used in automobile work a color salesman recently stated to the writer that whereas he formerly sold lakes in one-pound lots he is now selling them in 50-pound lots, and that, too, on a basis of from $3 to $5 per pound.

The first step in preparing the surface for the lake has to do with working out a fine, smooth surface condition. It is an axiom that the finer the surface the richer the color effect, which in large part is true. To get this fine, level and smooth surface is not always easy over a surface holding its old paint structure in fair condition, and upon which it is not feasible to apply roughstuff. In case of the application of the roughstuff over the old paint fabric puttying should at least be done upon the first coat of surfaces in order to fill up all fractures, cavities and shattered bits of wood. Then apply over this putty a couple of coats of roughstuff, which, in due course, are rubbed down to a level and smooth surface. The work is now ready to be coated in with color.

Should the surface be a new one from the wood up it is first primed, then coated with two good coats of lead, next puttied,







and then bodied up full and strong with four coats of roughstuff and capped off with a stain coat for the guidance of the workmen invested with the duty of rubbing the stuff out to the proper surface. Having reached this point we are ready to convey either the old or the new surface forward to a finish in practically the same order, and as follows:

For Munich lake first lay on a coat of Indian red saddened a bit by adding a little drop black. Then apply a coat of medium wine color thinning the color out to dry down flat. The following day take some of the lake proper, break it up in turpentine alone, and continue to thin to the proper working consistency with this fluid. With this flat color the surface, laying the pigment on with a camel's hair brush. Permit the coat to dry until the day following whereupon break, say, an ounce of the lake up finely in turpentine, and then to the mass use a full pint of elastic rubbing varnish, stirring all the ingredients thoroughly. With a half elastic, fine bristle brush, flat, flow the surface with a generous coat of the lake. After two days, rub the gloss from this coat with water and No. 0 pulverized pumice stone, using a felt 1-2 inch perforated rubbing pad. Then to a pint of the elastic rubbing varnish add a bare half ounce of the lake, stirring to an intimate incorporation of all the ingredients. Allow three days for this coat to nicely harden after which flat down uniformly as above. Then stripe, if so desired. The day following apply a clear coat of the elastic rubbing varnish which, after four days of drying out, may be nicely and uniformly rubbed down, washed up, touched up where necessary, and then finished with a strictly high-class finishing varnish.

English scarlet lake may be provided for by first using a peach blow colored pigment on top of which apply a coat of English vermilion made up with enough varnish to hold the pigment intact and give it the right working property. Make a glaze coat of the English scarlet lake and apply directly over this. English crimson lake works nicely and with admirable effects over quite the same ground, or with a ground of Tuscan red.

In the line of beautiful pigments none surpass No. 40 carmine, a lake of such magnificent effects that it is the popular idol.

This color is obtained in at least three different shades, this feature alone being important when arranging to try the pigment out. The one shade, say that of deep carmine, may over different grounds be made to show both light and dark color. For a deep No. 40 carmine build a ground of English Indian red. Over this ground next lay a coat consisting of one part deep wine color and two parts of the carmine, thinning the two pigments down to a brushing consistency with turpentine, adding as a binder a teaspoonful of new linseed oil to a pint of the thinned color. Over this color flow a glazing coat made up of elastic rubbing varnish stained with No. 40 carmine in the proportion of 3-4 of an ounce of pigment to a pint of varnish.

For a medium deep shade of carmine use light Tuscan red, laying the first coat of carmine as a flat color, then glazing.

For a light carmine lay the carmine first as a flat color then as a glaze color over a ground of English vermilion. In the use of carmine success depends in no small degree upon the quality of the pigment. Not a little of the No. 40 French carmine being sold to automobile painters and manufacturers, while chemically pure, has a muddy, lusterless tone, a defect which condemns it for good work. The carmine pleasing alike to critical buyers and connoisseurs carries a striking blood red

Digest

EXTRACTS FROM BEST FIFTY FOREIGN JOURNALS DEALING WITH SUBJECTS RELATED TO AUTOMOBILE ENGINEERING—A FORMULA FOR CRANKPINS—HEATED SCRAPER FOR REMOVAL OF PAINT

D. O. Barrett gives a series of formulas and diagrams for the calculation of crankshafts for single-cylinder motors of the four-cycle type and up to 75 horsepower. These have been applied in practice to motors of up to 60 horsepower and no failings have been noted in the shafts so calculated.

(1) *Shaft Diameter.*—The shaft's resistance to torsion is proportional to the cube of its diameter D, while the torsion moment applied to the shaft by the force of the explosion is proportional to the product of the bore B squared and the eccentricity of the crankpin, the latter being one-half of the length of the piston stroke S. From this:

$$\frac{B^2 \times \frac{1}{2} S}{D^3} = c.$$

The safety factor c, as used in practice, varies from 10 to 19 and averages 15.

The stroke S may be considered as a linear function of the bore B; S equals aB. Hence:

$$\frac{B^2 \times \frac{1}{2} aB}{D^3} = c = 15.$$

This gives for the diameter:

$$D = \sqrt[3]{\frac{a \times B}{30}}$$

In motors of the powers under consideration the stroke usually averages 1 1-2 times the bore, but it varies from 1 1-4 to 2 times the bore. For a equal to 1 1-25, D becomes 0.347 × B. For a equal to 2, D becomes 0.405 × B.

(The original here gives a diagram showing the shaft diameter for various bores and strokes, in inches.)

(2) *Dimensions of Crankpins and Bearings.*—In order to obtain the best results the mean pressure on the pin must not exceed 28 kilograms per square centimeter of projected surface. There is here allowed a mean pressure of 27.3 kilograms. Let l be the length and D the diameter of the pin, P_1 the mean pressure, of 27.3 kilograms. The total mean pressure equals the piston pressure per square centimeter multiplied by the bore B. Hence:

$$P_1 \times ld = 0.7854 \times B^2 \times \text{mean total pressure.}$$

Assuming this mean total pressure to equal 5.25 kilograms per square centimeter, one has:

$$ld = \frac{0.7854 \times B^2 \times 5.25}{27.3} = 0.151 B^2.$$

Usually l is made equal to d, and this means that d^2 equals $0.151 \times B^2$, or d equals 0.39 B.

If this formula gives d a smaller value than that of D, it should not be made smaller than D, but at least equal, and better, as high as 1.125 D.

For the bearings the dimensions should be:

The diameter, $d_1 = 1.1\,D$ and the length $l_1 = (1.75 \text{ to } 2) \times D$.

(3) *Dimensions of the Crankcheeks.*—Generally rectangular, these work against a beam fixed at one end. The resistance is directly proportional to the width b and to the square of the thickness t and inversely proportionate to the length, which latter is a direct function of the stroke S. The stress on the end of the cheek is proportional to the square of the bore, hence:

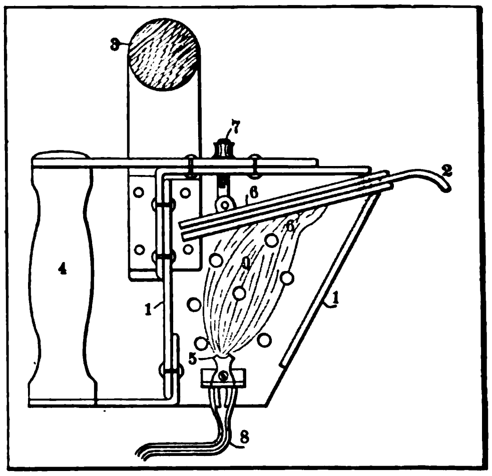
$$\frac{bt^2}{B^2 S} = c_1.$$

The constant c_1 obtained by averaging the values found on a number of motors, equals 0.045. The thickness t is usually 2.2 b and S equals aB. Hence:

$$\frac{t^3}{2.2 \times aB^3} = 0.045 \text{ or } t = B\sqrt[3]{0.999 \times a}$$

It is now easy to trace a diagram showing the value of t, as expressed in functions of the bore and the stroke, for the various customary values of a.—From *Technique Moderne* as quoted in *La Technique Automobile et Aérienne,* Sept. 15.

For the removal of paint or enamel from large metal surfaces, for which work either the blowtorch or a special chemical lye is usually employed, unless a sandblast is available, a method is recommended which is said to offer the advantage of always leaving the metal surface uninjured and in suitable condition for a new coat of paint. It also has the advantage of being less messy than other processes; it develops no fumes and may be carried on at any place in a factory and by unskilled workers. It consists simply in using a heated scraper. In the accompanying illustration 1 represents the sheet iron boxing, 2 the scraper, 3 and 4 the handles for operating the tool, 5 a gas flame jet, 6 guide irons for holding the scraper, 7 a screw and nut for adjusting the angle of the guide irons, 8 a flexible tube to the gas supply, 9 ventilation holes in the sides of the box.—*Metall Technik,* Aug. 27.



Heated scraper for removing old paint

Braking with the Motor in the Hills

An old tourist who has traveled much in the Alps and Pyrenees, in Italy, Switzerland and Tyrol, describes how he utilizes the compression in his motor for braking without drowning the spark plugs in lubricating oil and inviting fouling. He has a 20-28 horsepower vehicle weighing in touring condition and with two travelers 1,980 kilograms. At the top of the admission tube which comes from the carbureter he has made an opening one centimeter wide and three centimeters in circumference, which opening he can open and close from his seat. When he sees that he is going to reach the top of a hill and it dips down on the other side, he closes his gasoline pipe—from the seat—about fifty meters before reaching the top and relies on the fuel in the carbureter to take him up. Now, to descend, he drops to low gear (or second), opens the above-mentioned opening in the admission tube and leaves the contact of the magneto as for ordinary driving. Despite the excess of air he may have one or two explosions from the remaining gasoline in the carbureter, and he withdraws the magneto contact but restores it when the explosions cease for want of gasoline.

Selden Mechanically for 1911

PRESENTING THE MOTOR IN DETAIL, AFFORDING DIMENSIONS OF THE CRANKSHAFT AND THE AXLES, ETC.

THIS coming year the Selden car will be placed at the disposal of the clientèle of the Selden Motor Vehicle Co., of Rochester, N. Y., in five models, ranging in price from $2,250 for the Model T touring car to $2,600 for the Model 40-S fore-door touring car, the details of the respective models being given in the table as herein presented. Dismissing the commercial situation as it involves the body types, color of paint, and other matters, which the customers will readily be able to dispose of themselves if they inspect the cars, it will be the purpose here to show in precise detail some of the important mechanical details of design of the machinery part of the Selden make of automobiles.

The motor is identical in the several models of cars and is presented in a part-sectioned elevation in Fig. 1. This motor has four cylinders, cast in pairs, with T-heads, bringing the valves to one side. It is rated at 36.1 horsepower (A. L. A. M.) and the cylinders have a bore of 4 3-4 inches, with a stroke of 5 inches.

As Fig. 1 shows, the motor is of the water-cooled type, with integral jackets, excepting that the top is open and a separable top piece is bolted to flanged faces, so that the exterior of the domes of the cylinders may be gotten at and cleaned off, even to the extent of scraping, if in the course of time scale should form over these surfaces. The water is circulated by means of a centrifugal pump, the latter being gear driven, taking power from the half-time gear train. Ignition is by the type Bosch DR-4 magneto, with a storage battery as a source of auxiliary supply; the details of the ignition system will require no further attention here, it being the case that the interested reader may glean a better insight into the magneto ramifications by studying the literature as issued by the Bosch Company direct, which covers the subject much more thoroughly than is possible here, where the magneto is but one of the many details of construction to be considered.

Lubrication is by splash with a means for maintaining a constant level. Among the important details of the motor as shown in Fig. 1, mention will be made of the fact that the cylinder castings are of close gray iron, symmetrical in design, and are machined and otherwise brought to a precision of bore that assures tightness of compression, this condition being accentuated by the use of well-designed piston rings, that are fitted on an interchangeable basis. The valves are of the bevel seat type,

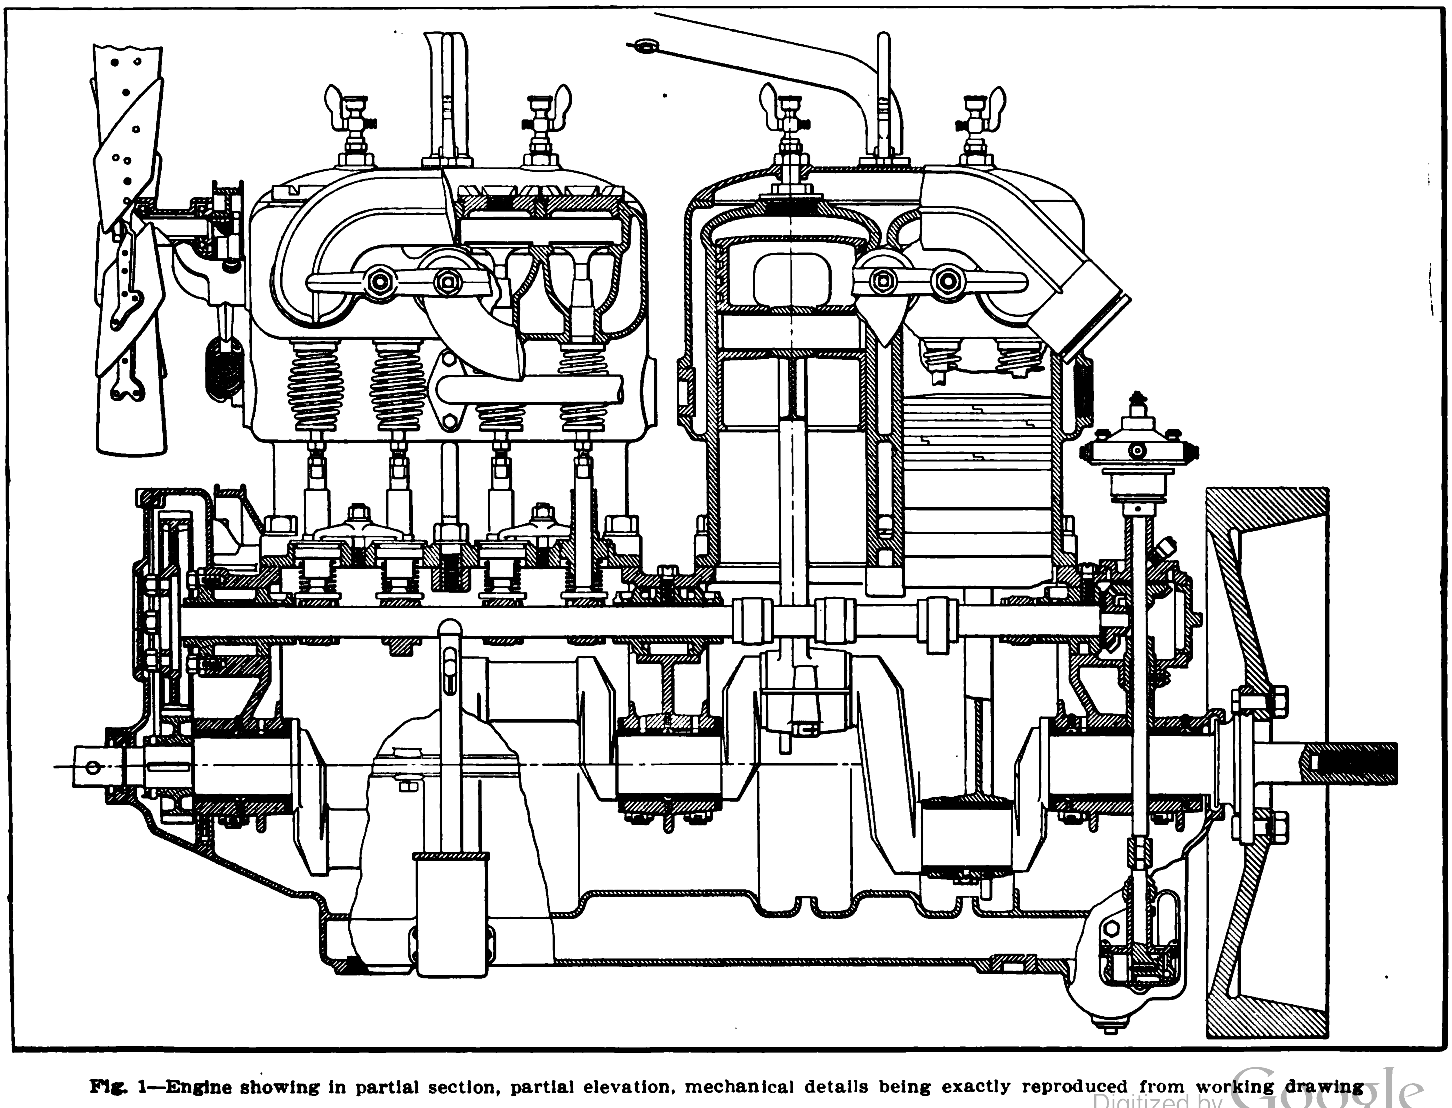


Fig. 1—Engine showing in partial section, partial elevation, mechanical details being exactly reproduced from working drawing

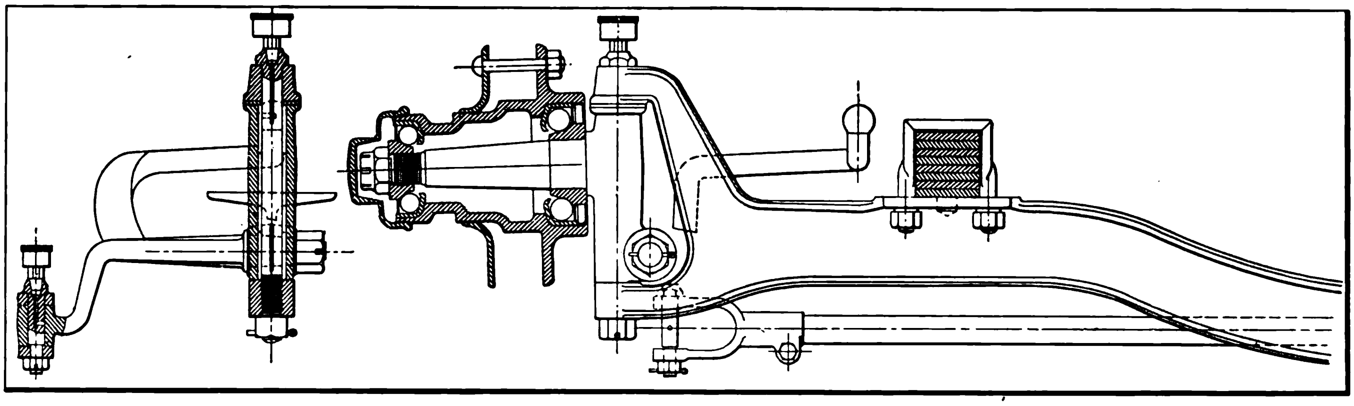

Fig. 4—Front axles are mounted on ball bearings of large diameter placed wide apart, and arranged to take thrust, also

and the water-jacketing around the valve seats is such that a uniform temperature obtains at every point. The valve stems are of large diameter, and at the point of intersection of the mushrooms with the stems extremely liberal fillets are provided, so that the heat that is wiped out of the contacting gases by the mushrooms is permitted to travel down the large area steps, from whence it is tapped away by the cold walls over a considerable area. This is a point that would escape the notice of a novice, until, in the course of time, the valves, if otherwise designed, would warp and resist being ground into tightness, due to the fact that the stems would curl up in response to unequal heat conditions, and it would be impossible to grind the valves into a condition of tightness. The valves are of large diameter, relative to the bore of the cylinders, so that at each inspiration the amount of gas taken in is relatively high, and the compression is so regulated that the power stroke is vigorous, but care is taken to maintain a condition of harmony of relation from a thermic point of view. The result, in practice, is that the motor has life, accelerates smartly, but the curve of torque is flat top, which has the advantage of affording a substantially constant range of power over a wide range of performing speed, and a thermal efficiency that makes it mark favorably on the fuel consumption. By carefully regulating the compression the troubles due to carbon precipitations are eliminated, but by using large area valves, and looking sharply to the condition of carburetion in the presence of efficient cooling the weight of mixture that is taken in per inspiration is relatively high, and the power of the motor is not only marked but this power holds over the wide range of speed that good practice demands. It is common opinion that silence of performance is due to mechanical accuracy in the machining and assembling of the parts; it may be as news to some, even discriminating automobilists, to learn that silence of performance depends upon the harmony of thermic relations as well as upon mechanical accuracy.

In view of the considerable cost of a crankshaft, and the importance of the service it renders in the motor, coupled with the fact that if it fails in service it is almost like losing a whole automobile, it is preferred to reproduce the crankshaft with all its dimensions just as the drawings are sent to the shop where the crankshafts are made, and in this way it will be possible to show not only the dimension of the sections and the bearings but the limits of tolerance within which the workmen must stay in the production of crankshafts. The main bearing is 5 5-16 inches long by 1 7-8 inches in diameter, so that the projected area of this bearing is sufficient and to spare to handle not only the torquing of the motor, but the gyrations of the flywheel as well. The bearing at the opposite end, since it has to do very much less work, is reduced to 1 3-8 inches in length, by 1 7-8 inches in diameter. The mid bearing is 3 3-8 inches in length by 1 7-8 inches diameter; this bearing has to shoulder a somewhat greater responsibility than the front bearing, but it has to do considerably less work than the bearing which supports the flywheel. The connecting rod bearings, that is to say the crankpins, are 2 7-8 inches long by 1 7-8 inches in diameter, and since

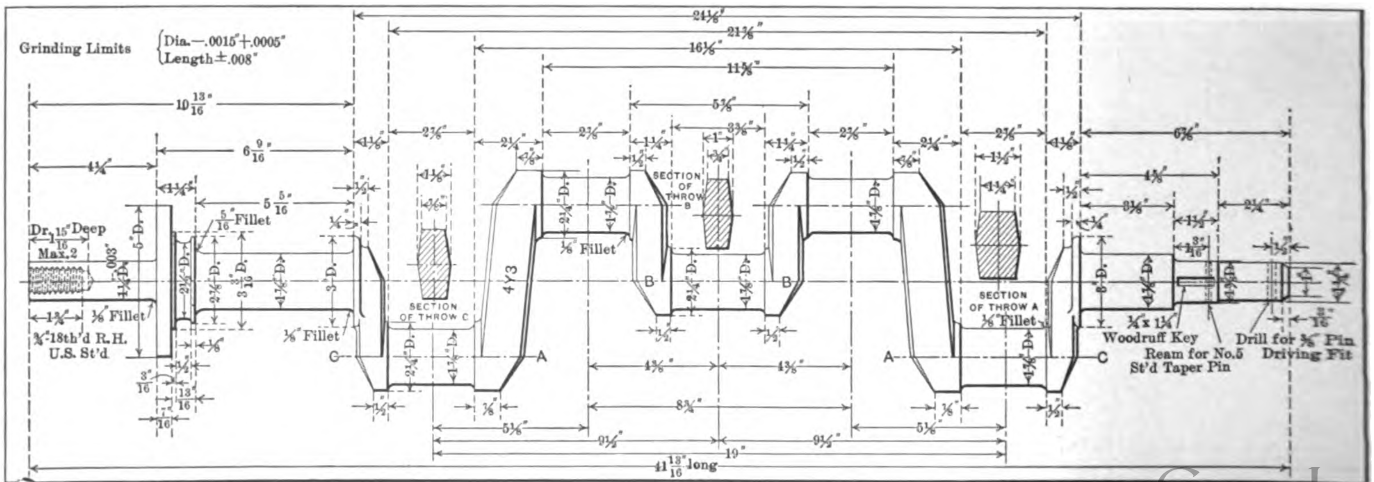

Fig. 2—Crankshaft of the Selden engine, showing liberal diameters and lengths with compactness and light weight

the work coming on each of them is the same they are all made alike. An examination of the section of the throws at A, B and C will afford information as to the rigidity of the crankshaft, especially if account is taken of the excellence of the material employed therein. At the upper left hand corner of this illustration it states that the grinding limits are, for diameters, from minus 0.0015 to plus 0.005, whereas, the limits of tolerance for lengths are plus or minus 0.008 (inches in each case). It is not impossible for good machinists on proper grinding equipment to keep within these limits of tolerance but it is not to be expected that the ordinary run of work, in the absence of a rigid inspection system, will adhere to this exacting standard.

As the tabulation shows, the transmission is of the three-speed and reverse selective system. Fig. 3 is a plan in part section of the same, in which the ratios of gears are given, indicating that the direct drive comes on high speed, which is obtained by sliding the sleeved second speed gear, the latter having backed off dog projections on its face, which engage with similar projections on the face of the master gear in juxtaposition. The master gears have 18 and 33 teeth respectively so that the layshaft travels at a little over half the speed of the main shaft. The low speed pinion has 18 teeth, and a reverse pinion has 14 teeth with a 16-tooth idler. The spindles are short in centers, made of a selected grade of material, and roll on Timken Roller Bearings with closures to prevent dust from coming in or oil from seeping out. The universal joint at each end of the main shaft slips over a squared end, and the block of the joint is broached square, and scraped to a press fit. The gears, besides being of large diameter, have liberal faces, and the material used is that which responds to heat-treatment on a basis to afford a glass-hard surface, supported by an elastic core. The shell is of aluminum, has a symmetrical exterior and is oil-tight.

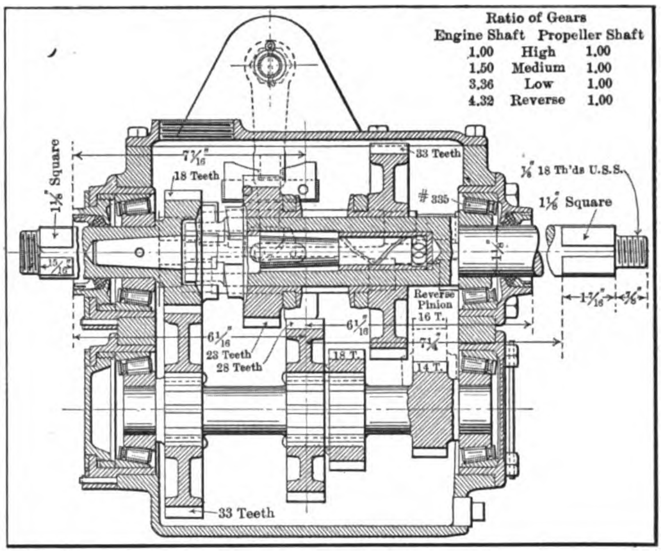

Fig. 3—Sectional drawing, showing transmission details

Referring to Fig. 4 of the front axle, which is of the I-section drop-forged in one piece from a suitable grade of steel, it will be observed that the knuckle has a long bearing, a through pin with a locking nut on the under side, and a grease cup is placed at the top by means of which the long pin bearing is maintaine din a profuse state of lubrication. The hub is sufficiently long to fix the centers between the ball bearings used so great that wobbling of the front wheels is prevented, and this desirable condition is further assured, due to the length of the steering knuckle arms, and the fact that the motion is straight line. While the subject of steering is up it will be apropose to examine the details of the steering gear as shown in Fig. 5, in which the spark and throttle to levers above the large diameter steering wheel, noting the excellence of mechanical detail and the care with which the work is executed.

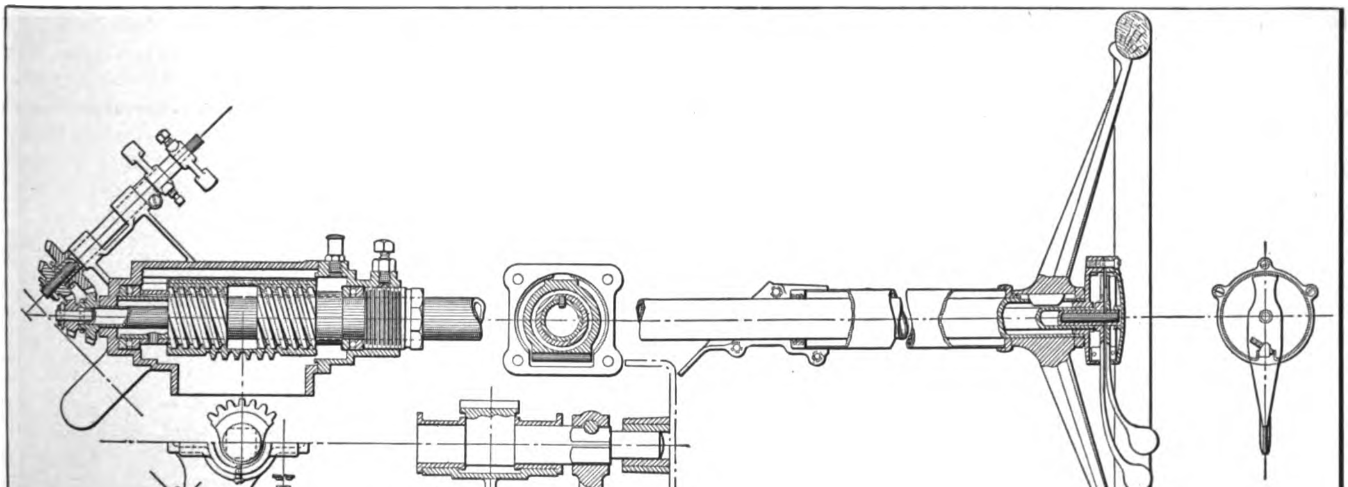

Fig. 5—Section through complete steering gear, showing double worm, hand wheel, and spark and throttle arrangement

McCord Solderless Radiator

DESCRIBING AN ELECTROLYTICALLY FORMED RADIATOR PATENTED BY "SOCIETE DES RADIATEURS ET REFRIGERATEURS"

ATTRACTED by the nice theory which underlies the construction of the radiator as patented by the "Societe des Radiateurs et Refrigerateurs of St. Ouen, France," and manufactured abroad by this company, remembering that this type of radiator has made its mark, it being used on such cars as Clement-Bayard, DeDion-Bouton, and Delaunay-Belleville, the McCord Manufacturing Company of Detroit, Mich., acquired the American rights to the patents of this system, and it is now manufacturing this type of radiator along the same lines as mark the products of the French firm, producing identical results, so that a description of this product in general will be precise for the McCord make as well as for the parent company. Fig. 1 shows one of the radiators as produced in the McCord plant, and before passing on to a description of the process of manufacture attention is called to the high finish, excellence of general appearance, and the substantial nature of the details involved.

Referring to Fig. 2 which is a section of a radiator of this type, mutilated to show the cells, and to bring out the waterway Wl, it will be observed that the thicknesses of the walls are just enough to afford stability, and the ratio of the thickness of the sheet of water as compared with the body of air that sweeps through the air cells is so regulated that a balance is obtained between the specific heat of air on the one hand, and the specific heat of water on the other, taking into account the controlling conditions, among which will be mentioned the better conduction of water for heat than that which obtains for air. Fig. 3 presents quite another view of the structural detail of the cellular part of the radiator, and the water passage-ways Wl are here brought into relatively bold relief, showing great uniformity of the thickness that obtains for the sheet of water, although in tearing the radiator apart the metal was somewhat damaged in the process, and to this extent allowance will have to be made for some variation in the apparent thickness of the water space. The process utilized in the manufacture of the cellular set being electrolytic, there are no joints to be solered at any point, and the passage-ways for water are entirely free and uniform with no chance at all of having portions of the passage-ways stopped up by accumulations of solder or other debris. The only point at which soldering is done is where the cellular set is inserted into the shell, resulting in the seams S1 and S2. These seams are riveted at A1, etc., around the whole distance after the meal is tinned over, so that the process of soldering is a mere matter of heating the metal to the melting point of solder when the tinned surfaces adhere to each other, but there is no excess of solder to run and clog up the waterspace.

Referring to Fig. 4, it will be observed that the water pipe M1 sleeves over the water pipe N1, and a joint is formed at the point F1 to afford mechanical strength. The water enters in the direction of the arrow, passes into the distributing pipe as shown, and is distributed out through holes H1 on the underside of this pipe, there being a sufficient number of these holes to deliver the total supply of water without undue friction, but the area of the holes as combined is just enough below the area of the pipe to cause the water to spray, and as it sprays out of the holes. It is delivered uniformly over the whole top of the cellular set, thus inducing a condition of uniformity of the cooling process that bespeaks efficiency on an accentuated basis, due to the elimination of cold zones in the body of the radiator. This illustration has the further value of showing how the radiator is put together with a double seam at the joint K1 and an overlap at the joint K2; the front joint K1 is so made as to avoid the necessity of riveting, but the joint K2 at the back, and its mate K3 below, are riveted R1 and R2 as well as being sweated and soldered. This view presents additional evidence of the uniformity of the water space, and it shows, in some measure, the strength of the metal obtained by the electrolytic process, the evidence of strength being in the tearing of the metal during the process of sectioning the radiator for the purpose of presenting it here.

In the manufacture of this radiator a pattern is first turned out, and from this pattern a casting is poured, using a lead composition for the same. The lead casting is subjected to a cleaning process such as will brighten the surfaces and permit of utilizing the electrolytic process which follows. In the electrolytic process, copper is deposited over the lead casting until the entire surface of the lead is covered with a homogeneous coat of copper to a sufficient depth to make a series of stout walls forming the cells of the radiator as shown in Fig. 2. After the copper is coated over the lead to the required depth, the electrolytic process is stopped off and the unit in this state is transferred to a heating bath which is maintained at the temperature of melting lead, and since this temperature is below the temperature of melting point of copper the lead casting is reduced to the molten state and the lead is thus gotten rid of, leaving the copper in the form as shown in Fig. 2. There are a series of nice ramifications, and to some extent, trade secrets, that have been worked out during the evolution of this type of radiator, but the result in practice is entirely commercial, and the radiators so made are found to be not only uniform in construction, but entirely free from the annoying leaks that abound when joints are poorly soldered; moreover, the surfaces are highly efficient because the wall thicknesses are uniform, and there are no accumulations of solder to impede the flow of water or stop up the passageways. These radiators have been made for some time in France and are in common use there, and the McCord Manufacturing Company expects that this latest move on its part marks a new era in radiator work in this country.

A Word to Car Owners

Owners of automobiles can save themselves money and annoyance by providing their men with a few extra tools that are not usually found in the ordinary kit supplied with the car; they will facilitate the man's work and be an incentive for him to better look after the small troubles that cars are prone to.

A man who comes home after a long day's work late at night, having been driving from early morning, has little inclination to start work on the car and it cannot be expected of him. What time has he for such things as valve grinding? The act of valve grinding takes a comparatively short time compared with the taking out of some types of valve springs. Men do not consider that they are paid to make tools for the car as well as drive it, although some men take a delight in inventing special tools for their cars, and such men should be encouraged. A simple tool would greatly facilitat the removal of valve springs and he man would then have time to grind say one or two a day as they wanted it. This can be made with a piece of steel rod by bending it at ont end to enter the valve plug after same has been removed so that it touches the valve head. Two elbow bends can then be made in the rod so that it follows the shape of the exterior of the cylinder casting dropping perpendicularly to just above the height of the valve cotter; here a hook is made to act as a leverage for a lever with a forked end to place under the spring cup.

Two-Cycle Elmore

THE 1911 ELMORE OUTPUT INCLUDES THE PERFECTED HIGH-DUTY MOTOR, MANY MECHANICAL REFINEMENTS, AND UP-TO-DATE AUTOMOBILES

THE most important single feature of the 1911 announcement of the Elmore Manufacturing Company, of Clyde, Ohio, is that which conveys the news that, in response to an insistent public demand, a new model—No. 25—has been placed on the market. The company calls it "the small car," but it is small only when compared with the regular line—Models 46 and 36. The new car has a four-cylinder motor rated by the makers at 30 horsepower, and is made in four-passenger tonneau and two-passenger runabout types.

The regular Elmore models, which have made the two-cycle valveless engine famous, will be continued, but with not a few important changes, among which may be mentioned a change in the design of the 36-B body and the installation of the new "High Duty" type of four-cylinder motor of 50-horsepower in place of the 36-horsepower motor of 1910, with identical changes in the 46-B model, with the exception that the 1911 motor will deliver 70 horsepower.

The 1911 wheelbase lengths have been increased as follows: Model 46-B, from 120 to 124; Model 36-B, from 110 to 114. The new Model 25 has a wheelbase of 108 inches. The 46-B seats seven; 36-B five; the two No. 25 models, four and two, respectively, for touring car and roadster.

The tire equipment of the Elmore calls for 36x4 front and rear for the 46-B, 34x4 front and rear for 36-B and 32 x 3 1-2 for the new Model 25.

Those who have not followed Elmore practice closely will have to be told that the "high duty" motor is a wide departure from former Elmore practice. The earlier types of motors of this make were of the crankcase compression type, whereas, in the "high duty" type as it is employed in 1911 work, the initial compression is brought about by employing compression chambers and a double-diameter type of piston as here illustrated.

Exhaust Side of Model 25 High Duty Motor

An examination of the exhaust side of this motor shows the four individual cylinders C1, C2, C3 and C4 with an equal spacing between them and a symmetrical water manifold W1 with a leg connecting to a header at the top of each cylinder, utilizing holding-down bolts B1, B2 and B4 to hold the manifold in place with a flexible connection (hose) between the radiator, which is placed at the front of the fans, and the extremity of the manifold E1, which is so shaped as to serve as a secure anchorage for the hose. The remaining water manifold, W2, has a leg terminating at the low level of the water in each cylinder, and the method of bolting this manifold is somewhat different from that of the manifold W1, it being the case that the lower water manifold N1 and the exhaust manifold N2 are pressed against the flange faces on the cylinder by means of yokes Y1, Y2, Y3 and Y4. The studs that hold the yokes pass between the two manifolds and the nuts N1, N2, N3 and N4 on the studs are out in the open so that suitable pressure can be applied without difficulty. The fan F1 is driven by a belt which passes over a grooved pulley from a grooved driving pulley G1, the latter being actuated by power taken from an extension from the distributor shaft. This view of the motor shows the oil connections O1, O2 and O3 between the points of distribution of lubricating oil within the crankcase and the oil pump P1, which is sunk in the oil well between the last cylinder and the flywheel F2. The pump is of the force-feed type, and the supply of oil is taken from the sump S1, which, as will be observed, is commodious. By means of covers C5 and C6, which are readily removable, access may be had to the lower part of the crankcase, through large handholes, for purposes of cleaning.

SPECIFICATIONS FOR ELMORI

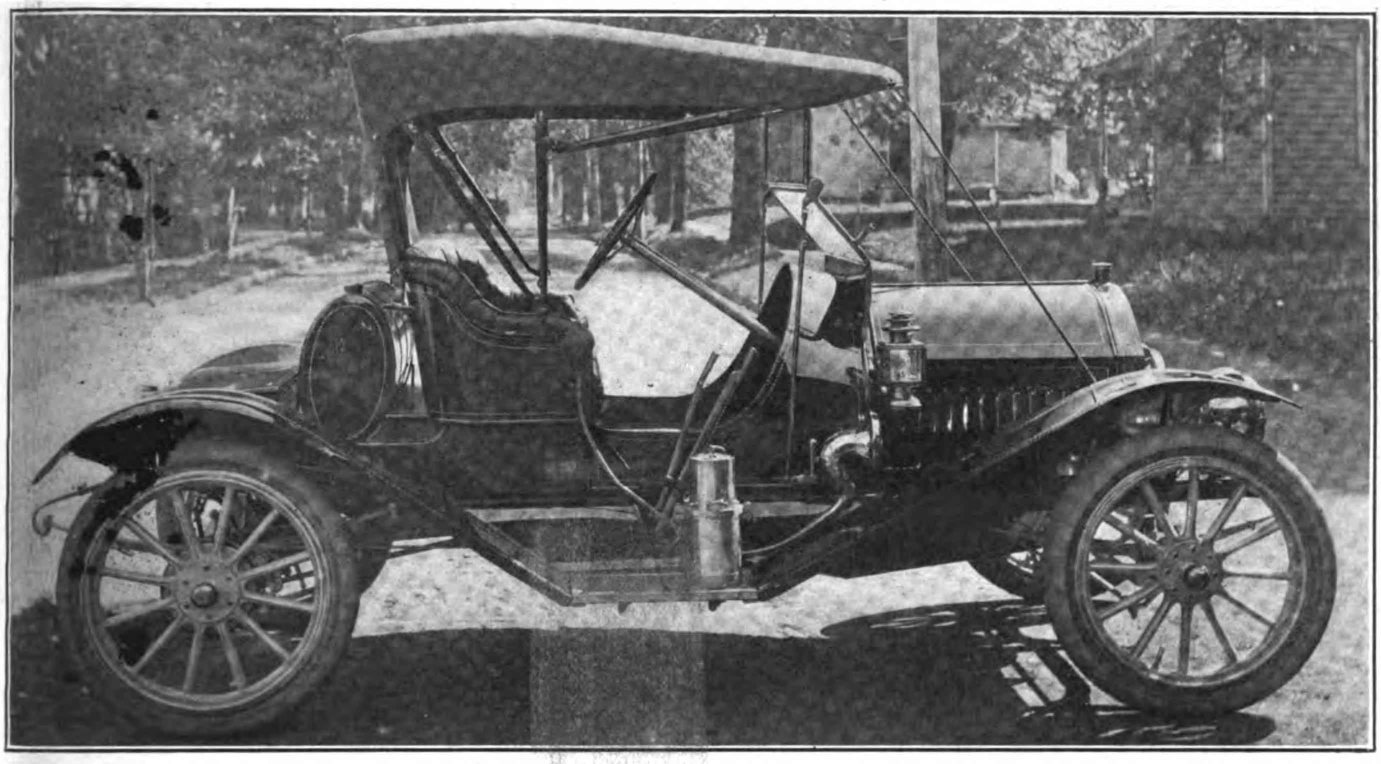
Model 46-B—Fore-door type of five-passenger touring car with straight-line effect, overhanging cowl, protective mudguards and other nice relations



Model 25—Roadster, seating two persons, with an overhanging cowl, open entrance, commodious oval gasoline tank back of the seat and a tool box on the deck at the back

The view of the Model 25 motor shows the carbureter C1 with its manifold connection M1 terminating in an orifice with a flange face F1 on the top of the crank case in a position half way between the two extremities of the motor, so that the four cylinders C1, C2, C3 and C4 are in a position of vantage as respects the supply of mixture and the carbureter is permitted to work with the greatest possible facility. The lever L1 is connected to a motion which is under the control of the driver, and this lever is pressed over the end of the shaft S1. This shaft connects with the mechanism that controls the shifting of the distributor, the office of which is to distribute mixture to the respective cylinders on the two-cycle principle.

CARS AS OFFERED FOR 1911

	TRANSMISSION							BEARINGS				TIRES	
Clutch	Type	Speeds	Location	Drive	Wheelbase	Tread	Frame	Crank-shaft	Trans-mission	Axle	Weight	Front	Rear

Disc	Selecti'e.	3	Motor..	Shaft ..	124	56	P. Steel..	Plain..	Ball.....	Ball....	3200	36x4	36x4

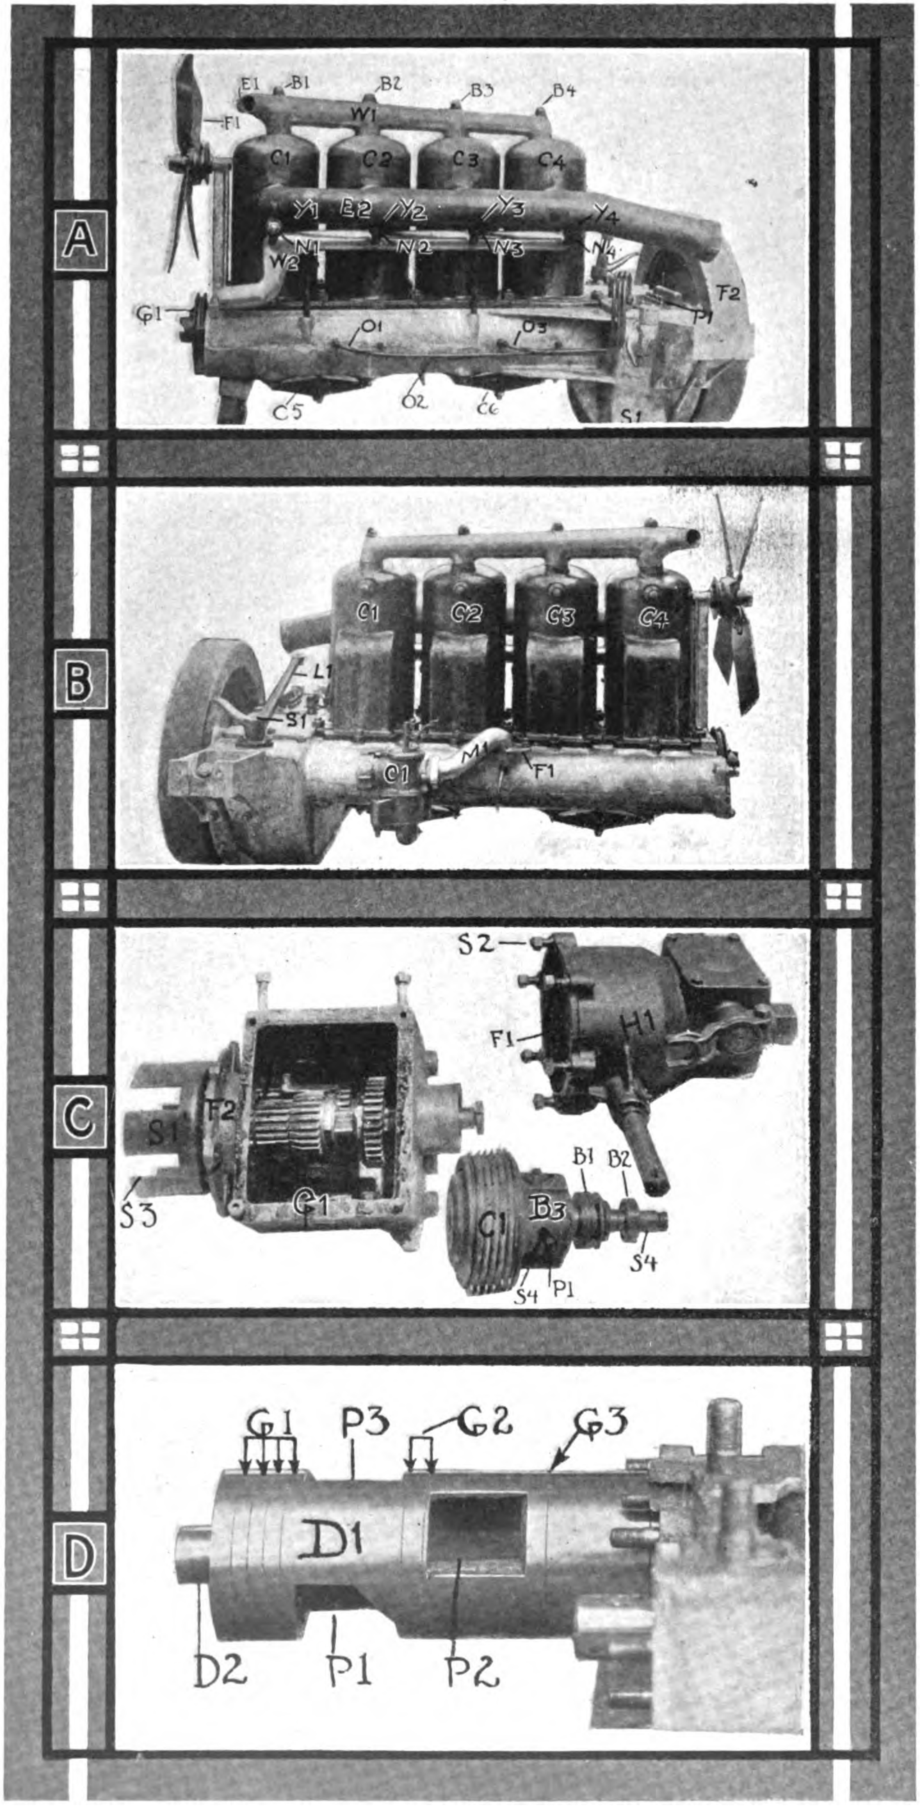
The design is cleverly worked out in practice and is quite free from parts that are likely to become deranged.

Utility of the Distributor in Model 25 High Duty Motor

Referring to Fig. D of the distributor of the Model 25 motor, it will be observed that the distributor D1 is partly withdrawn from its housing, disclosing the reduced diameter D2, which accommodates the annular type ball bearing, also the ports P1, P2 and P3. It will be understood that there are a sufficient number of these ports disposed over the length of the distributor to serve for the control of the incoming mixture on the one hand and the exhaust on the other, working on the two-cylinder principle, which gives a power stroke per revolution of the crank shaft for each cylinder of the motor. The distributor is ground to exact size and floated on the ball bearings, care being exercised not to permit the diameter of the distributor to touch the bore of its housing at any point. The clearance is regulated through the thickness of the sheet of lubricating oil that is used in maintaining proper lubrication of the motor, and it has been found in practice that the distributor is packed to absolute tightness by cutting grooves G1, G2 and G3 around the diameter of the distributor between each pair of ports, with the exception that there are four such grooves at the extremities of the distributor. It was pointed out that the distributor is connected with a shifting mechanism through the good office of which the distributor is not only moved in the axlewise direction, but it is given an angular displacement as well. The object in thus manipulating the distributor is to regulate the inflow of mixture at the will of the operator so that the compression may be increased or decreased, as the exigencies of service would seem to indicate. Because of this facility, it is possible to run under conditions of low compression, if the occasion requires, without suffering the inconvenience of "crankcase shots." It will be worth explaining that in the older forms of two-cycle motors it was not possible to utilize large transfer ports and take advantage of low conditions of compression, due to the fact that crankcase shots were invariably present as the speed was increased, the latter being the basis of decreasing compression on account of wire drawing of the mixture. Then, too, increasing speed brought on its measure of decreasing scavenging perfection, and in the long run it was deemed expedient to so design the conventional types of two-cycle motors that the transfer ports were of relatively small area, and the power delivered from motors so designed was below the best expectation. It is the fair claim of the Elmore company that the use of this distributor, combined with a method of timing it, corrects the evil tendency as noted, so that the power of the motor is very materially increased and the flexibility of its performance is also brought to a satisfactory level.

Assembled Crankcase of Model 25 High Duty Motor

A study of the crank case will show the crank shaft C1 with six main bearings M1, M2, M3, M4, M5 and M6, five of which



A—Exhaust side of Elmore engine
B—Carbureter side of Model 25 engine
C—View of gearbox and clutch forming a unit.
D—View of distributor as installed on Elmore engines

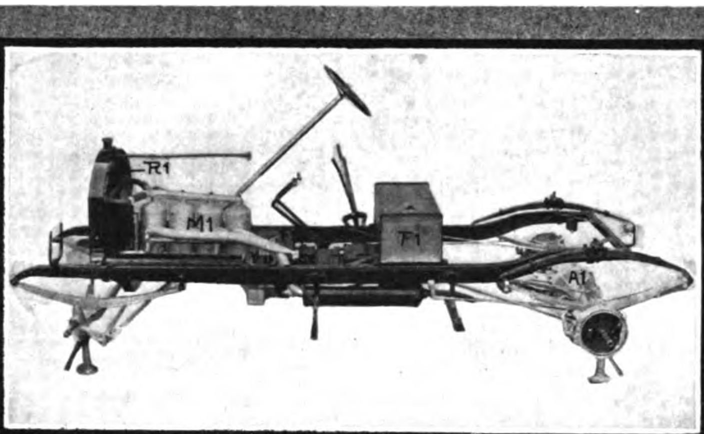
support the load as it is delivered by the four crankpins P1, P2, P3 and P4, and the sixth bearing carries the weight of the flywheel which is pressed onto the end of the shaft at E1. The distributor is in the rounded portion of the crank case R1, and is carried by annular-type ball bearings, one of which is pressed onto the end of the shaft at B1, from which the cover has been removed for purposes of explanation. The intake manifold flanges to register with the orifice O1. From the distributor mixture passes to the cylinders through the ports as shown at P5, P6, P7 and P8, but it will be observed that there are two ports at each point, and it will be enough to state that the remaining port is for the exhaust. It is important to understand that the incoming mixture is always impelled in one direction only, so that there is no inertia to overcome, but this property does add to the potential which moves the gas into the cylinders so that the supply of mixture to each cylinder per cycle is greater than would be true in the absence of this principle of design. The distributor is driven by means of the gear G1 on the crankshaft, which meshes with a mate G2 on the distributor shaft. The distributor is given axlewise motion by the level L1, and is rotated through a certain angular displacement due to the conformation of the gear G3.

Details of Model 25 High Duty Motor

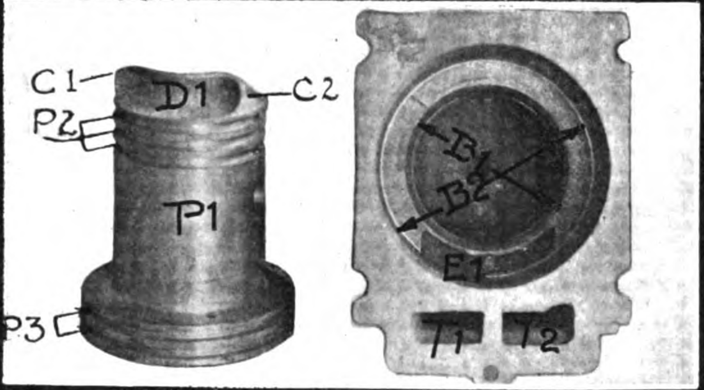
This motor, instead of utilizing crank-case compression, is so designed that the cylinders have two bores. The piston P1 has a small diameter which fits in the smaller of the two bores B1, and the enlarged extremity of the piston fits in the larger of the two bores B2. There are three packing rings P2 for the small bore and two packing rings P3 for the enlarged portion. Mixture and exhaust enter and pass out of the transfer ports T1 and T2, entering the enlarged part of the cylinder at E1. The head of the piston is provided with a deflecting plate D1, which contacts with the bore of the cylinder at C1 and C2. The four cylinders of the motor are identical as to design and in explanation of the flange it is enough to state that there are really eight single-acting cylinders, utilizing four double pistons under conditions as follows: The large diameter pistons work as air compressors, taking in mixture on the suction stroke, compressing and delivering it to the power cylinders on a 2-cycle basis. Since there is no leakage to speak of in connection with the air compressor portion of the cylinders, it is possible to definitely figure upon the supply of mixture that will enter the power cylinders: moreover, the compression in the power cylinders may be nicely regulated by fixing the compression in the air compressor division of the cylinders. As the result of a long series of experiments extending over two years on an energetic basis, the best air compressor compression was arrived at and the proportions of the transfer ports were so fixed as to bring about harmony of the relations. It was also found by experiment, trying many successive methods, that the shape of the deflector plate D1 follows no definite law that can be discovered, but there is a shape for each size of motor that does deliver the best result, and this shape has been adopted in the Elmore type of motor. A study of the piston P1 will disclose its niceties of design; it is long, affording an adequacy of bearing surface, and the walls are designed for lightness without sacrificing strength sufficient to prevent deformations. The piston rings are of the compound type; one master ring fits in the groove in each case and it has a pair of auxiliary rings encompassing it so that tightness is the result of the combined action of the nest of rings in each case. This plan has proven to be thoroughly good in every way, and it has the further advantage of longevity, which is something worth counting in a motor.

Features of Model 36-B Axle

In order to obtain a clear idea of the details of design and construction of the semi-floating type of live rear axle of the Model 36-B car, it will be necessary to study the cross-section (page 589). Power is transmitted to the axle from the propeller shaft through the driving spindle pinion S1, thence to the pinion P1, which meshes with the bevel gear G1, the latter being flanged to the differential housing H1, which rotates with the gear. The differential system is made up of a nest of bevel gears comprising a pair of suns S2 and S3, engaging with planets P2 and P3. The jackshaft members J1 and J2 engage with the suns S1 and S2 by means of square extremities on the jackshaft members which fit snugly in broached square holes in the suns S1 and S2. As the torque of the motor is delivered through the propeller shaft and the relating members to the bevel gear G1, the housing of the differential system is given rotation in the right or left-hand direction, depending upon the position of the sliding gear lever. The torque is delivered to the planets G2 and G3 and is weighed out to the jackshafts J1 and J2 in proportion as the tractiveability of the two rear road wheels is present. If one of the road wheels offers a better tractiveability than the other, the torque of the motor is delivered to it on an increasing basis. In going around a curve the two road wheels are free to turn at their respective indicated speeds, it being the case that the outer wheel must travel a greater distance in a given time than the inner wheel. The differential system is capable of weighing out its torque to the respective wheels despite the fact that they do not rotate at the same speed. Glancing at the

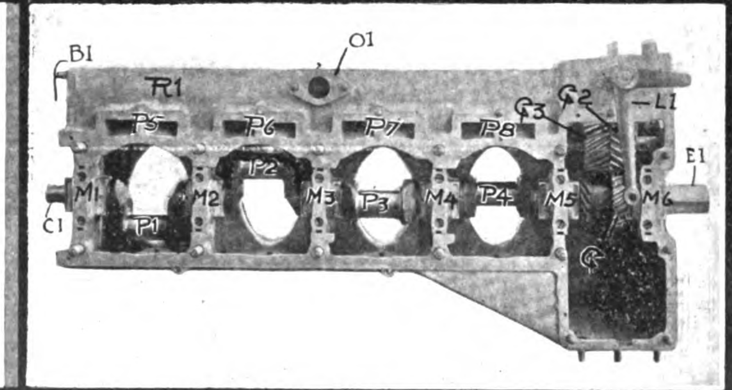


E



F

G



H

E—View of chassis, showing exhaust side of motor
F—View of piston and cylinder section.
G—Surfacing of crankcases at Elmore plant
H—View of crankcase, crankshaft and gears

outer extremity of the jackshaft J1, it will be observed that it is finished with the shoulder S4, against which the inner raceway R1 presses, and the diameter of the shaft over which the ball bearing is driven is ground to a size which assures a sucking fit. Just outside of the ball bearing the shaft is again reduced to a size that makes a press fit for the thinner extremity of the hub H2, with a clearance C1 between shoulder and the final diameter of the shaft, in which the keys K1 and K2 are fitted, there being keyways to match in the hub H2. When the hub of the wheel is pressed on, the hub nut N1 is screwed on and a cotter pin C2 is then pressed through the hole, engaging one of the castellations of the hub nut. The hub cap C3 is then screwed over the enlargement of the hub; a relatively fine thread is chased in the hub cap so that when it is screwed into place and brought up firmly against its shoulder the cap will then remain as put until it is removed by the operator. The flange F1 of the hub, which is integral with the same, is of relatively large diameter so that the spokes at the miter are firmly clamped by means of the bolts B1 with the brake drum D1 serving as the inner clamping member. The brake drum is of unusual merit, due to the fact that it has a double rim, the inner portion of which R2 serves as the face for the internal expanding brake, and the outer portion R3 serves as the face for the external expanding brake, the band B2 of which being shown in section with a fire proof fabric for a facing, the latter character of material also being used for the facing of the inner brakeshoe system. The inner brakeshoe is expanded by applying torsion to the shaft S5 by pulling on the lever L1, and the outer brakeshoe is contracted by applying torsion to the shaft S6 by pulling on the lever L2. The woodwork in the wheel is of second growth hickory selected from well-seasoned stock and suitably treated in the process; bastard spokes are entirely eliminated, and care is exercised to cast out wormy and discolored wood. An examination of the tube T1 will show that it is of good diameter and fair thickness of wall, that it telescopes the relating members sufficiently to make a long snug bearing and rivets are placed at points of vantage to prevent the tube from withdrawing. The ball bearings throughout are designed to take thrust and radial load simultaneously and closures C3, C4, C5 and C6 are so placed as to prevent foreign matter from entering the bearing enclosures, while grease cups are located so that all the moving parts as well as the bearings are maintained in a state of profuse lubrication. The exterior appearance of the axle is agreeable, the design is symmetrical, the quality of the material is selected with discriminating care, heat treatment is resorted to on a basis of intelligence and the machining porcess is conducted with sufficient precision to assure that the parts will pass a rigid inspection.

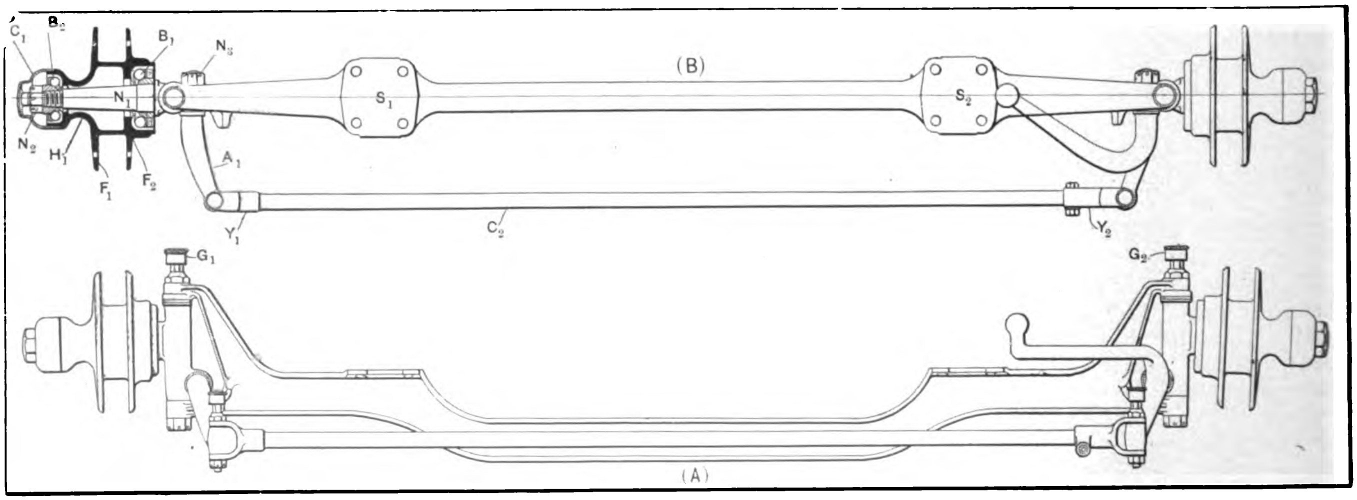
Model 36-B I-Section Front Axle and Scheme of Design

Referring to the illustration of the Model 36-B front axle, A shows the same in elevation and B is a plan. The axle is of the drop type with spring perches S1 and S2 with flanged holes for a pair of U-bolts, by means of which the springs are clamped into secure relation. Glancing at the cross-section of the hub H1, it will be observed that the fixed flange F1 is to the outside, and the movable flange F2 comes to the inside. Cup and cone type ball bearings B1 and B2 are used, and they are separated by a distance sufficient to support the load and prevent wobbling of the wheel. The knuckle N1 is drop-forged from a suitable grade of steel and properly treated to induce kinetic quality. The inner races of the ball bearings are pressed on sufficiently to prevent them from working loose, and the hub and nut N2 is screwed up tight and is prevented from backing off by a cotter pin which passes through a hole in the end of the spindle and engages with the castellations in the nuts. The hub cap C1 matches with the hub caps on the rear wheels, and the general appearance of the axle is in keeping with the art motive of the design. The steering arms A1 are drop-forged from special steel and are prevented from turning by suitably disposed keys, and are also prevented from coming off by the nut N3, which is also locked on by means of a cotter pin. The cross rod C2 is a tube and straight threaded at its extremities to accommodate the yokes Y1 and Y2. The bearings at all points are proportioned in view of the results of experience and grease cups G1 and G2 afford a means for suitably lubricating the knuckle pin.

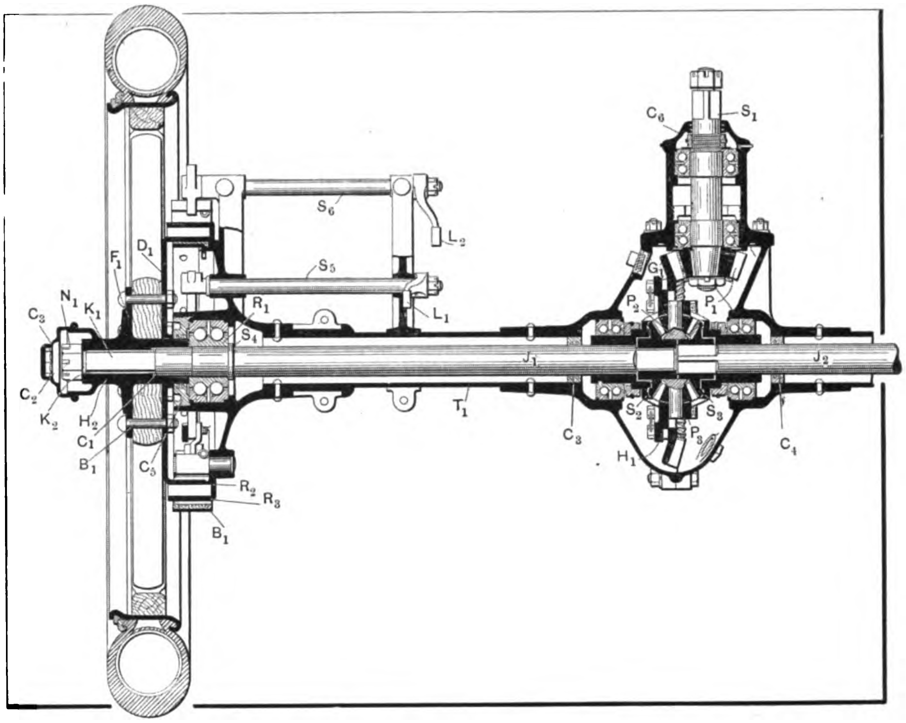
It is recognized that cost of maintenance is too high if the questions of lubrication are not properly cared for and that these questions of lubrication are of far more importance than is generally well appreciated.

Clutch and Transmission Combined in a Unit

From the clutch point of view there are three principal schemes of design in vogue, placing the clutch either in conjunction with the motor as a unit with the transmission gear, the latter being separate, or incorporating the clutch into the gear system and combining the latter with the rear axle. In the Model 25 Elmore system the clutch is combined with the transmission, making a unit in common for the two, but this unit is placed amidship on the chassis frame, separated from both the motor and the live rear axle. Referring to Fig. C, the transmission gear system G1 of the three speed and reverse selective type is provided with a clutch spider S1 at the front end, into which the clutch C1 is nested and the cylindrical housing H1 encloses the clutch, the flange face F1 bolting against the flange F2, being held in place by six studs S2 in the manner substantially as shown. The multiple-disc clutch has 13 plates, 6 of which engage in the slots S3, so that they are prevented from rotating, excepting with the spider S1, seven of which are splined to the shaft S4. Axlewise thrust is compensated for by the ball thrust bearing B1, and radial work is cared for by annular type ball bearings, one of which, B2, is indicated. The clutch is engaged when the block B3 is given an angular motion, due to the travel



Plan and elevation of the I-section front axle as used on Model 36-B car, showing symmetry of design, carefully worked out details, and the elements of a harmonious relation to the rear axle design



Cross-section of the Model 36-B semi-floating type of live rear axle showing a bevel differential, bevel drive, ball bearings designed for radial and thrust loads, double-faced brakedrum and other appropriately designed members.

of the pins P1 in the cam slots S4. The entire construction is noted for its substantial character, simplicity reigning throughout.

General Relations in Model 25 Chassis

The chassis frame is of the channel section steel, with a kick-up at the rear, thus bringing the power plant low down and making the center of gravity of the car as low as it is possible to have it so that the road performance of the car is on a high plane and the turning over speed on a curve is maximum. Referring to Fig. E the radiator R1 is placed on the chassis frame in the plane of the front axle and the motor M1 is suspended so that the flywheel is given adequate ground clearance, making the transmission a substantially straight line in the plane of the crankshaft back to the live rear axle A1 when the springs are depressed the amount due to the weight of the machinery, chassis, body and passengers. The rear springs are of the full-elliptic (scroll) type, related to the chassis frame through trunnions, utilizing double U clamping bolts, and provided with rubber bumpers, which, however, do not come into play, excepting under overload condition, traveling at very high speed and in an emergency at that, involving an abrupt change in the road level. The front springs are half-elliptic, provided with rubber bumpers, are fastened to perches with double U-bolts and are clamped down tight. The fuel tank F1 is rectangular, placed above the top of the chassis, coming under the front seat of the car, so that it is high enough to take advantage of a gravity feed to the carbureter. There is an entire absence of castings and irregularly shaped parts; the chassis presents a clean appearance at every point and care is exercised to make the fit of the relating members so close as to prevent noise and rattle without, at the same time endangering the freedom of motion of the relating parts.

Important Variations from Four-Cycle Practice

It will be understood that the principle of the 2-cycle motor is substantially a revel in simplicity, but there are certain characteristics of this type of motor that have ever been stumbling blocks to those who, laying great stress upon absence of complication, overstep the bounds to the extent that they more or less disregarded the mechanical problems involved. Referring to Fig. G, it will illustrate the point here to be made; in this illustration the surfaces of the crankcases are worked down to a level far more perfect than will be possible by any machining process whatsoever. It may not be generally understood, but if two pieces of metal are perfectly smooth when they are brought together, they will resist being separated. This adhesive tendency is due to the fact that the perfectly surfaced parts when they are brought into contact with each other exclude the atmosphere when the atmospheric pressure, which will be on all the surfaces, excepting the surfaces of contact, will hold the two members in contact with each other, and the force of the engagement will be that due to a pressure of 14.7 pounds per square inch. The illustration shows how this process is conducted on the machine faces of the crank case in which S1 is the surfacing block, which, when it is blued over and motion is imparted to it so that it traverses the machine surfaces of the crankcase, the high spots over the machined surfaces will partake of the blue and the next operation is to use a scraper S2 in the process of removing the high spots. This operation is continued and repeated a sufficient number of times to bring about the desired perfectly straight surfaces so that the cylinders, which are given the same treatment, will make tight joints with the crankcase. The success of the Elmore type of 2-cycle motor is a legitimate dividend of the care with which the machine operations are conducted, remembering that the simplicity of the 2-cycle type of motor does not serve as a license to disregard the necessities.

There will be no change in the prices as compared with 1910. Models 46-B and 36-B will remain at $2500 and $1750 f. o. b. factory, respectively, while the new Model 25 will be listed at $1250 for the touring car and $1200 for the roadster. Elmore equipment includes lamps, horn, tools, etc., of a grade in keeping with the rest of the car. Top and windshield are extra.

Foreign Motor Car Imports and Exports

From the figures published the exportation of French cars shows an increase in value. Up to the end of August of this year the exports were $23,568,800.00, as compared to $19,274,400.00 for the same period of 1909. Great Britain heads the list as the largest consumer, the exports to that country having increased from $8,591,415.00 to $9,678,600.00. The following countries also show an increase: Germany, Belgium, Switzerland, Italy, Austria, Russia, The Argentine, Turkey and Algeria. But the number of cars shipped to Spain, United States and Brazil show a decrease. The imports also show an increase from $976,000.00 to $1,166,000.00 for the first eight months of this year over a like period of last year.

Some interesting figures concerning the motor car imports and exports of Great Britain have just been published by the Board of Trade of the British Government.

Besides the actual exports, the cars and parts that were imported and re-exported are taken into consideration, as they should be, to find out the state of the actual position of the country's business.

The imports for the month of August, 1910, shows an increase over other years of $50,000.00 and less cars were re-exported by $219, which shows a larger proportion of home purchases. The net exports of British made cars was $1,065.290.00, against net imports $259,395.00. For the eight months ending August 31, 1910, the total imports of cars and parts was $17,127,970.00, against a net exportation of British cars of $7,483,220.00, being an increase over last year's figures of $2,970,940.00.

Loss of Compression

Editor THE AUTOMOBILE:

[2,379]—With reference to your answer to Question No. 237 in last week's issue I have a motor fitted with four piston rings to each cylinder, these constantly move around in the manner you describe. Cannot something be done with the present rings to keep them in place without buying 16 new rings and having them specially cut in the manner you suggest? W. H. T.

Trenton, N. J.

Yes, another method sometimes employed is to pin the piston as shown. The positions as marked in the accompanying sketch, Fig. 1, you will find a great improvement in the compression. The iron from which pistons are made is very brittle, consequently tapping should be very gentle and the pins should be inserted so that there is no fear of them coming out either inside the piston or out against the cylinder walls. One pin dislodging itself is sufficient to spoil an engine.

Worn Valve Stems and Guides

Editor THE AUTOMOBILE:

[2,380]—I have a motor four years old and the guides and valves are badly worn. Can this wear be remedied without rebushing? T. R. T.

Allentown, Pa.

After considerable use the hammering on the base of the stem of the valve causes wear and the distance between the lifter and the valve will be too great and prevent the valve opening to its full extent. In older models of gasoline motors where adjustable lifters are not employed, two methods may be used to overcome this fault without purchasing new valves or lifters. Small caps should be made to fit under the feet of the valves and afterwards case-hardened. Amount of clearance between valve and lifter should not be more than the thickness of a visiting card.

Another way is to take the valve to a competent man and let him heat the stem near the base and draw it out slightly. Great care, however, should be taken that it is perfectly straight afterward, otherwise it will not pass through the guide.

When the valve guide is badly worn the following method may be resorted to in order to temporarily overcome this. A small collar should be made and drilled to a good working fit for the valve stem, as the sketch shows (Fig. 3). In the case where the guide is cast with the cylinder it requires great care and the use of special tools and jigs not everywhere obtainable to rebush, otherwise the holes would be almost certain to be out of alignment with the valve seating. A good permanent job can, however, be made in the following manner when special tools are not obtainable: Turn the old guide below the line C-D away, also above A-B. A guide similar to E and E1 in Fig. 2 should be made from phosphor bronze with a slightly tapered head. The cylinder should be bored to accommodate this, allowing for an infinitesimal amount of side play. The conical fit will allow the valve to find a perfect seating as the spring's action will keep the new part in position.

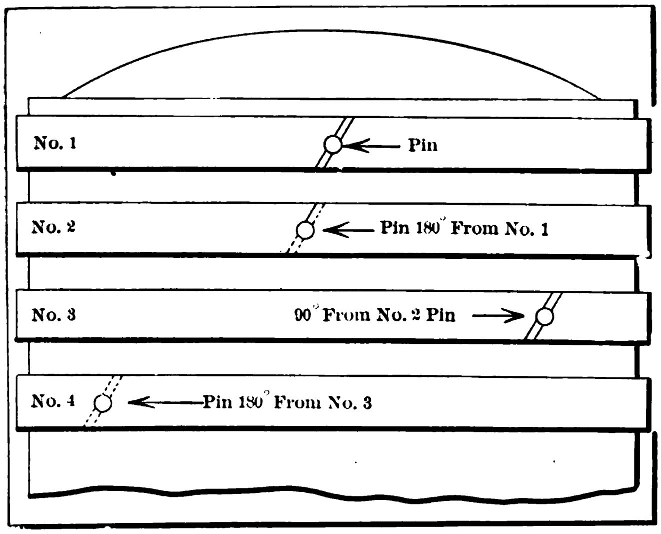

Fig. 1—Illustrating methods of keeping pistons in place

Castor Oil Will Silence Noisy Gears

Editor THE AUTOMOBILE:

[2,381]—The gears of my —— car have become noisy lately yet seem to be in good mechanical order. Can you suggest anything to quiet them? A SUBSCRIBER.

St. Joseph, Mo.

Provided the bearings are all tight and filled with oil-retaining discs of felt castor oil should overcome the noise. Under no circumstances use it for the engine, but in the gear box and rear construction it will work wonders if you can keep it in.

Piston Clearance in Cylinders

Editor THE AUTOMOBILE:

[2,382]—Will you kindly explain through your columns if your answer to letter No. 2,361 relative to piston clearance is correct? In this answer, you state that the clearance at the top of piston should be about half as great as on the bottom. This is exactly opposite from what we have always understood to be common practice, that is to say, the top of the piston being hottest should require the greater clearance. This subject is a very interesting one and the writer would be glad to read your explanation.

Quincy, Mass. FRANK T. CABLE.

The reason for the larger clearance of the piston and the cylinder at the top than at the bottom, is according to the figures taken not being as small as they might be, but nevertheless such that work well in ordinary touring cars that do not need excessive compression, to prevent excesses of oil passing by the piston. The amount of expansion of cast iron from which pistons are made is 1:909 at 212 degrees Fahr., does not perceptibly effect the amount of clearance, but by having the top larger than the bottom the lubricant is sucked up in the form of a cone with the apex towards the top and less likely to pass than if the apex was the other way as it would be if the bottom of the piston was larger than the top.

Freewheeling Down Hills

Editor THE AUTOMOBILE:

[2,383]—I have arranged a magneto cut-out on a high-grade six-cylinder touring car; the engine has a bore of 4 1-2 inches and a stroke of 4 3-4 inches. I make a practice of stopping the engine by short circuiting the magneto at the top of long hills, and coasting down with the transmission in direct drive and clutch disengaged. Near the bottom of the hill I crank the engine with spark retarded and throttle nearly closed, by gradually engaging the clutch. Is this practice hard on the car? R. R.

Park Row, N. Y.

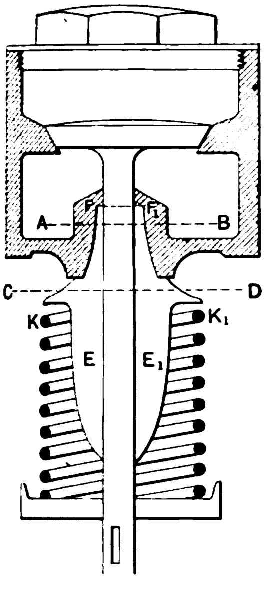

Fig. 2—Method of repairing worn valve stems.

The practice of cutting the engine out and coasting down long grades has a beneficial effect on the car because the engine can then be used as a brake as well as receiving a cooling through the inrush of air through the radiator while no heat is being generated. It is preferable, however, to start the engine with the spark half advanced instead of fully retarded. As long as the engagement is effected gradually no harm can be done to the car. Great economy in gasoline will be noticed if this method of driving is carried out. On long hills you should alternate the use of the foot brake with the hand brake and not use one all the time; far too many people rely on the foot brake to do all the work of stopping and when they require the side brake in a case of emergency they forget they have such a thing on their car.

The Construction of Automobile Axles

Editor THE AUTOMOBILE:

(2,384)—What are the different considerations to be taken into account in the construction of an axle? ENGINEER.

Williamsport, Pa.

Elements of usual sections:

A = area of section. b = breadth. h = depth. D = diameter.

	Shape of Section.	Moment of Inertia	Moment of Resistance	Square of Least Radius of Gyration.	Least Radius of Gyration
	Solid Rectangle.	$\frac{bh^{2*}}{12}$	$\frac{bh^{2*}}{6}$	$\frac{\text{Least}^{2*}\ \text{(Side)}}{12}$	$\frac{\text{Least side*}}{3.46}$
	Hollow Rectangle.	$\frac{bh^2-b_1h_1^{3*}}{12}$	$\frac{bh^2-b_1h_1^{2*}}{6h}$	$\frac{h^2+h_1^{2*}}{12}$	$\frac{h+h^1}{4.89}$
	Solid Circle.	$\frac{AD^{2*}}{16}$	$\frac{AD^*}{8}$	$\frac{D^{2*}}{16}$	$\frac{D^*}{4}$
	Hollow Circle A, area of large section; a, area of small section.	$\frac{AD^2-ad^2}{16}$	$\frac{AD^2-ad^2}{8D}$	$\frac{D^2+d^{2*}}{16}$	$\frac{D+d}{5.64}$
	Solid Triangle.	$\frac{bh^3}{36}$	$\frac{bh^2}{24}$	The least of the two: $\frac{h^2}{18}$ or $\frac{b^2}{24}$	The least of the two: $\frac{h}{4.24}$ or $\frac{b}{4.9}$
	Even Angle.	$\frac{Ah^2}{10.2}$	$\frac{Ah}{7.2}$	$\frac{b^2}{25}$	$\frac{b}{5}$
	Uneven Angle	$\frac{Ah^2}{9.5}$	$\frac{Ah}{6.5}$	$\frac{(hb)^2}{13(h^2+b^2)}$	$\frac{hb}{2.6(h+b)}$

	Deck Beam.	$\frac{Ah^2}{6.9}$	$\frac{Ah}{4}$	$\frac{b^2}{36.5}$	$\frac{b}{6}$

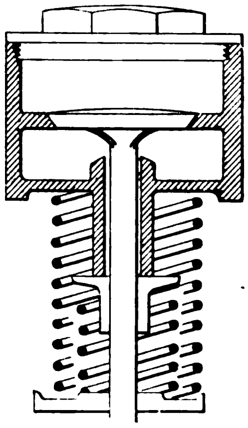

Fig. 3—Method of temporary repair for worn valve guides

The usual form of axle used in the construction of automobiles of the present day is the I-section stamped from the solid bar of steel of adequate strength. The construction of the axle is only one factor that has to be taken into consideration; the other is the quality of the steel employed. In order to determine the dimensions of the section we must first of all take a weight that it has to carry, and as all cars vary in this particular, suppose that this is represented by the letter W. The strains an axle has to bear are the superweight, torsion strain rounding curves and the shocks occasioned by impact with obstacles on the road surface.

The form the axle is usually stamped is shown in Fig. 4, the boss at the point F being particularly adaptable for the shape of the mould; to determine the sizes of A B and C the angle G and the width of D and E it is necessary to resort to the known formulæ on the matter.

First to find the safe load in pounds that the axle can support the following table, compiled by the Pencoyd Iron Works, gives the following, where the load is distributed:

Where L = length in feet between supports.
A = sectional area of beam in square inches.
D = depth of beam in inches.
a = interior area in square inches.
d = interior depth in inches.
w = working load in net tons.

1. $\frac{1{,}880\ Ad}{L}$ 2. $\frac{1{,}880\ (AD-ad)}{L}$ 3. $\frac{1{,}400\ AD}{L}$

4. $\frac{1{,}400\ (AD-ad)}{L}$ 6 and 9. $\frac{1{,}860\ AD}{L}$ 10. $\frac{3{,}560\ AD}{L}$

11. $\frac{3{,}200\ AD}{L}$ 12. $\frac{2{,}900\ AD}{L}$

based on fiber strains of 16,800 pounds for steel (see table).

After the weight the axle has to carry has been determined the modulus of the section can be found from

$$\frac{D \times (A+B+C)^3 - (D-E) \times B^3}{6\,(A+B+C).}$$

The modulus of the section or the value of the section for purposes of calculation of the moment of resistance multiplied by the strength in pounds per square inch in tension with elastic limit of the material of which the axle is made will give the bending moment or corresponding moment of resistance.

Supposing the axle to have a superweight of 2,000 pounds and from the modulus of the section (which are usually supplied

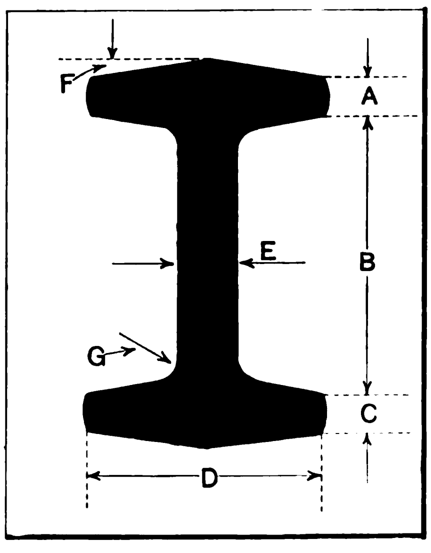

Fig. 4—Section of I-type axle; the arched tops are used to suit the moulds in stamping

by the makers of the steels) the dimensions necessary for the axle to carry this weight can be found. But besides the superweight there is to be taken into consideration the force exerted by the weight behind the axle when the wheels come in contact with obstructions on the road.

If the weight behind the axle is say 2,500 pounds, when it strikes the obstacle the bending arm between the spring clips and the center of the wheel will be subjected to side torsion strains which will effect the moment of resistance in proportion to the speed at which the car is traveling.

The height of the center of gravity of the car in respect to the height of the axle will also have to be taken into consideration, as the higher the center of gravity is placed so is the forward thrust changed to a twisting strain.

To arrive at this calculation the axle is considered equivalent to a beam fixed at one end and loaded at the other, or the section should equal the length of the bending arm multiplied by the load on the axle multiplied by the pressure due to extreme impact in pounds per square inch divided by the strength in pounds per square inch in tension with the electric limit of the material of the axle.

Outside Wheel Subject to Greatest Strain

Editor THE AUTOMOBILE:

[2,385]—Have heard the matter discussed as to whether the strain is on the outside or inside wheels of an automobile when turning a curve, and the matter is not settled in my mind. Can you tell me upon which wheels the strain really is in turning a curve, say around a one-eighth mile circular track?

Meadville, Pa. J. H. PARDEE.

The greater strain is undoubtedly on the outside wheels, which ever direction the car is going. The reason for this is that centrifugal force tends to throw all the weight and strain upon the outmost point of contact which is the tires, and it is for this reason the outer tires always wear out in races on circular tracks quicker than the near side ones. The off-side front wheel receives the greater part of the strain, as it is on this wheel that the strain caused by the centrifugal force added to the forward push is impinged. To clearly show this one only has to take the example of a side slip on a greasy road; if the brake is applied in rounding a curve the slip throws the car outward, forcing the back round and making the outside front wheel the center of the arc of the circle described.

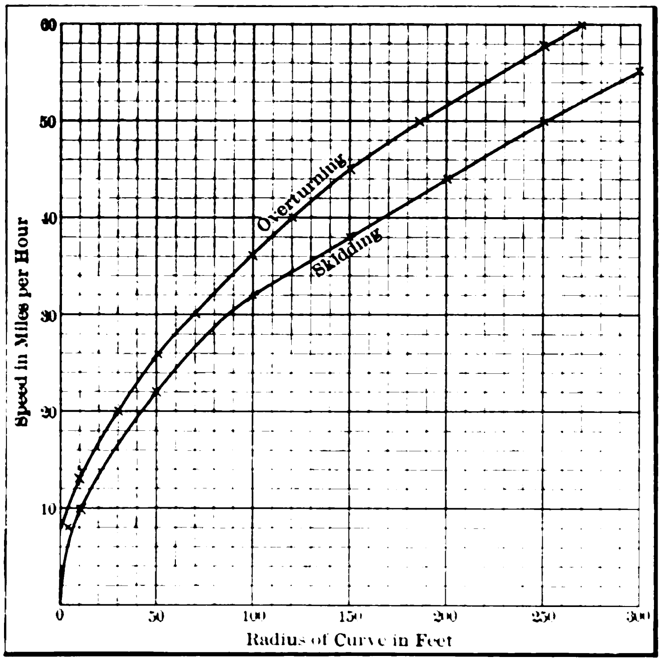

Fig. 5—Diagram showing critical speeds of road curves of different radii

Taking the weight of the car and passengers as 2,240 pounds, the height of the center of gravity 2 feet 6 inches, the wheel track of 4 feet 6 inches and 0.66 pounds coefficient friction or adhesion of the weight on the tires,

$$F = \frac{2{,}240 \times 2.25}{2.25} \;.\; 2{,}016 \text{ pounds,}$$

2.25 being half the wheel gauge of 4.6, therefore, 2,016 pounds is the amount of centrifugal force necessary with the dimension given to commence overturning.

On a curve of a given radius, *e.g.*, 100-feet, radius of one-eighth mile circular track = 105 feet

$$\text{we have } \frac{g = \sqrt{2{,}016\,gr}}{w} \div 1.46.$$

R = radius of curve in feet gravity or 9 = 32.2 and w = 2,240 weight of car.

$$V = \frac{\sqrt{2{,}016 \times 32.2 \times 100}}{2{,}240} \div 146 = 36.69 \text{ miles per hour.}$$

The speeds are shown in curve in Fig. 5.

Magnetos Don't Break Crankshafts

Editor THE AUTOMOBILE:

[2,386]—Will you kindly answer the following for me: Is it possible to break the crankshaft of a four-cylinder motor with a make-and-break spark if the timing is not set as it should be set, the cylinder having a bore of 3 3-4 inches, with a 1 1-4 inch diameter crankshaft, or if two cylinders were timed right and the third cylinder timed so it fired far in advance, would this cause the crankshaft to break? INFORMATION.

Newark, N. J.

Chauffeurs' Lot in Honolulu

Editor THE AUTOMOBILE:

[2,387]—I have been reading THE AUTOMOBILE a long time and take the liberty of asking you what you know of the automobile proposition in Honolulu in the Hawaiian Island.

I have heard that drivers get good pay there (that is, American drivers).

I have had over seven years' experience, three and one-half years in the East and a little over four years in the West.

Canon City, Colo. BARRETT E. SIBLEY.

With reference to your inquiries respecting the automobile proposition in Honolulu, we have pleasure in informing you that place is growing with the advancement of the sugar-growing industry. The officials of all these concerns own automobiles; besides these gentlemen most of the government officials run cars as well as the better-class natives. There is a motor carnival held in Honolulu each year as well as a battle of flowers. Most of the cars are of American manufacture, and there are probably fifty that take part.

The cost of living is high, and it is not thought advisable to go out on speculation unless money is no object, and it is infinitely better to obtain some sort of employment before arriving.

Automobile driving is about the hardest work that is done by whites, all manual labor being done by natives.

Why Is There Such a Great Difference?

Editor THE AUTOMOBILE:

[2,388]—I took a demonstration in an automobile; it was satisfactory, and I then purchased one of this make and model, but now that I have it I find that it does not ride nearly as well as the demonstrating car. The tires are of the same diameter, but I notice that the tires on my car are 3 1-2 inches in section, whereas the tires on the demonstrating car were 4 1-2 inches in section. Would this make any great difference? ED. C. ATKINSON.

Chicago, Ill.

The difference will be in proportion to the square of the section.

Questions That Arise

CONCERNING TEMPORARY REPAIRS TO A LEAKY GASOLINE TANK; CAUSE OF EXCESSIVE WEAR ON FRONT TIRES; HOW TO COUNTERACT SIDE-SLIP; HORSEPOWER FORMULAE, ETC.

[239]—What is the best way to get home if the gasoline tank leaks?

A flexible metal pipe about six feet long is a very useful accessory to always carry on the car, to replace a defective or broken gasoline or oil pipe. A case came before our notice some time ago where the small pipe conveying the gasoline inside the tank (under pressure) from the bottom to the connection at the top became unsoldered, making it impossible for the car to proceed, although the tank was full.

To take the tank off, walk several miles with it and wait while the fumes evaporated would have taken too long; so some method had to be devised to temporarily overcome the trouble.

The only means possible was to fix up a gravity siphon. The only piping on the car was the copper tubing for the acetylene headlights, and this was clogged with a high explosive composition caused by the action of the acetylene on copper. The driver's companion held an emergency can of gasoline in his arms and the pipe was introduced into the gasoline tank; then the regular gasoline feed pipe was cut by a file (the only cutting tool on the car), near the carbureter and a joint was made between the emergency and regular pipes with the rubber connections from the headlamps.

Before this last operation was effected the driver placed the end of the pipe out of the tank in his mouth and sucked through it, causing the siphon to work, coupled up and ran for 70 miles.

When coming to solder the pipe in the tank afterwards he learned to his cost the necessity of leaving a tank that has had gasoline in it for a very long time without putting a flame to it. The tank was left overnight with both connections undone (top and bottom).

Air was pumped through the tank next morning for two hours with a tire pump and when a flame was then put to the tank a terrific explosion took place.

[240]—What is the cause of excessive wear on front tires?

It is not necessary for the tires to be bad or faulty for abnormal wear to show under 1,000 miles. It is probably due to the front wheels not being in alignment with the rear wheels; or it may be caused through some defect or backlash in the steering preventing the wheels from falling to the proper angle which they should when turning a corner.

[241]—How can a punctured float be repaired on the road without solder?

As a temporary method of repairing a punctured carbureter float, the use of sealing wax may be cited. In cases where the float has flooded, through the perforation of the solder, the first thing to be done is to bore a small hole in the float, in order to let out the accumulated liquid, and the surface should be carefully cleaned round the puncture. A piece of sealing wax should then be obtained, and a few drops melted over the hole, and pressed well down, in order to fill it up. It will then be found that the float is again good for any number of miles. One advantage of this method is that the wax adds little weight to the float. It is advisable to moisten whatever article is used for pressing in the melted wax, in order to prevent its sticking.

[242]—What is the weight of cast-iron compared with that of deal patterns?

Multiply the weight of the pattern by 17.

[243]—Why does the spark plug in the back cylinder of a four-cylinder motor become sooty and covered with oil while the other three remain clean and fire perfectly?

The cause of this is either the oil feed to the back end of the base chamber is allowed to run too fast, or the baffle plate dividing the front pair of bases from the back pair is not high enough to prevent the oil from flowing back while the car is going up hill. It would be thought, however, that in going down hill the return flow would equalize itself; the reason it does not is that going down hill the motor is not usually working fast, whereas going up hill the speed of the motor is increased on account of driving on a lower gear.

To overcome this fault empty the bases of all oil and pour in fresh to an equal level and adjust the lubricator so that the front base feeds faster than the rear. If this does not stop the backward flow it is necessary to fit higher baffle plates. The oil in the base chamber of a gasoline motor that depends upon splash lubrication becomes more like a vapor than a liquid after the motor has been running for a short time, and the faster the speed of the engine the smaller the particles become.

[244]—How is the action of a side slip to be counteracted?

To take it for granted that a side slip is inevitable under certain conditions is a very poor excuse after an accident has happened. In the first place most side slips are due to carelessness and miscalculation; of course a driver of an automobile cannot be held responsible for the idiosyncrasies of other users of the highways, and what would be considered a safe speed on a clean road would be highly dangerous if other traffic were about.

Supposing the driver of another vehicle immediately ahead of you pulls out without warning across your path while you are traveling at 12 miles per hour on a greasy road, you have no alternative but to apply your brakes or smash into him. This operation, however, is often the cause of a side slip, but if carried out in the following manner the slip will be greatly minimized:

The moment you perceive the vehicle in front of you begins to deviate apply a hard pressure on your brake, temporarily locking your back wheels and at the same time turning your steering wheels in the direction the obstruction proposes to go. (For this illustration it is to be understood that you are following the correct rules of the road as regards passing and that there is no obstacle coming in the opposite direction.) The harsh application of the brake should be only momentary and the steering should then be thrown over to the opposite side to counteract the effect of the first brake effect. The brake should be applied till the momentum of the car is brought to the required speed, but in jerks and not by continual pressure. The movements of the steering wheel must be decisive, because slow movements or greasy roads are liable to cause a front-end skid, which is infinitely worse than a rear skid; the car becomes as uncontrollable as a boat without a rudder. The action of turning the front wheels quickly squeegees the moisture from under the tire and gives it a temporary purchase which is in most cases sufficient to alter the course of the motion.

Applying the brake in jerks is certainly not good for the car but infinitely better than a collision.

If you find yourself sliding toward the curb, so that the rear will strike first, turn your steering wheels toward the curb also, as perhaps by the time you reach it the front wheels will have changed the motion of the slip and allow you to graze it with a forward slide instead of a direct blow that often causes a broken wheel.

[245]—What are the formulæ for figuring horsepower used by the various automobile associations?

A.L.A.M. $D^2 \times n -:- 2.5$.

Royal Auto Club of Great Britain. $(D+L)^2 \times n -:- 9.92$.

$D =$ Diameter of cylinder in inches.

$L =$ Stroke of piston in inches.

$R =$ Revolution per minute of crankshaft.

$n =$ Number of cylinders.

Dont's

INJUNCTIONS COVERING A VARIETY OF SUBJECTS BEARING UPON THE AUTOMOBILE FROM THE SEVERAL POINTS OF VIEW AND SAGE ADVICE TO THE MAN WHO WOULD ENTER WHERE ANGELS FEAR TO TREAD

Don't come back from the races and bore your neighbors about your hair-breadth escapes; a miss is as good as a mile.

Don't catch the racing fever so badly that you will have to apologize to every policeman that you meet on the roadside; your brand of enthusiasm may not be as catching as the smallpox.

Don't forget that racing cars frequently wear out a few thousand dollars worth of tires in a single day; speed is what does it.

Don't overlook the fact that these large tire bills are generated by this high speed, despite the fact that the road is especially prepared for the purpose; even less speed on a bad road will have substantially the same effect.

Don't let the claws out from under the velvet. If you do persist in abusing your tires and then ask the maker to replace them on the ground that they were defective. just be nice when he tells you that he knows better.

Don't display the cloven hoof to the fellow who walks; if you meet him on the road it will cost you nothing to slow down to a respectable pace, and he will think that you are a white man.

Don't stop at a small garage by the wayside, have the radiator of your car filled with water, borrow tools with which to make repairs and go away without showing a little appreciation.

Don't hypnotize yourself into believing that a fore-door type of car will be too warm for Summer time; it certainly will be comfortable in the Winter time, and when the dog days arrive you can throw the fore-door away if you want to.

Don't abandon a top because it is travel-stained; it may be coaxed into first-rate shape by the sparse application of a little good leather dressing, but it will be a grave mistake to apply this dressing. copiously. A little dressing and a little work, that's all.

Don't put your automobile out of commission and figure upon using the tires as a savings bank for mud; they should be cleaned and stored in a well-ventilated, dark place. Castile soap and tepid water will make a good solution with which to clean them.

Don't overlook the fact that the lining of an automobile top will present a better appearance than otherwise if it is occasionally brushed. A whisk broom is a satisfactory instrument.

Don't delay polishing the brass work with the understanding that you will do a good job when you get at it; there will be an entire absence of good brass work when you start on a delayed basis.

Don't give the brass work a "lick and a promise": the lick is all right, but the verdigris that forms continuously will get the best of your promise.

Don't lay too much stress upon "selling points" that may not exist in the car you are talking about; for all you can tell, the "prospect" might be endowed with sense enough to look into the matter.

Don't sandpaper the lacquer off of your new lamps; it is transparent coating that will prevent the lamps from tarnishing for a long time. When it becomes shabby, it will be time enough to dissolve the lacquer by applying alcohol.

Don't acquire the hallucination that there is a material defect at some point in the car you are paid to dispose, and then work the salesman's trick of bragging about it on the ground that it is a particularly new and brilliant idea; fools rarely have money enough to buy an automobile.

Don't put protectors over the lamps to hide the dirt that you failed to take off; for all you know a rainstorm might come along and wash them for you.

Don't be the character of salesman who jabbers about the kind of steel that is used in the car you are trying to unload; if you know anything about the material used, it will be time enough to say so.

Don't work overtime trying to carry conviction; you don't have to; just tell the truth.

Don't forget that a prospective really wants to know how bad the car is, not how good; tell him.

Don't make a $500 automobile out to be a $5,000 affair; if a prospective comes along with $500, why not give him what he wants?

Don't talk to the prospective while making a demonstration; he may not care to listen to your version of the last scandal; what he wants to know is, how will the automobile perform? Show him.

Don't do "stunts" with the car you are demonstrating; you take an undue chance with your prospect; the customer is not entitled to a car that will do any more than perform well.

Don't exaggerate the speed possibilities of the car; it will be a pleasant diversion to find a demonstrator who will not lie about the speed. Sensible customers much prefer to merely realize that the performance is satisfactory.

Don't squander your time lolling around in front of a garage waiting for a call; it will be more profitable all around if you will put in your idle moments lubracting the bearings of the automobile.

Don't own a garage that is not provided with a room for the accommodation of the chauffeurs; a gang of them hanging around the front of the building will drive your best business away.

Don't overlook the fact that ladies do not enjoy stopping at a garage that has a gang of loafers standing around in front of it.

University Professor Wanted as Chauffeur

workrooms, 6th floor.

CHAUFFEUR wanted, experienced, safe, careful; excellent mechanician, ready and able to make repairs and take care of machine; willing worker all hours, polite, neat; single, young; speaking fluently Spanish, French, English; able act employer's valet, secretary; if have knowledge typewriting, stenography, the better; give references. Diplomat, 511 Herald.

CHAUFFEUR, coachman wanted; one who had experience Packard cars and car driving state exper

The above advertisement in the help wanted columns of a New York newspaper recently has attracted an immense amount of notice in motordom of the metropolis. The requirements are so clearly stated that no mistake could be made. The main difficulty about the whole matter would be to find any human being who possessed all the essentials asked for by the would-be employer.

If the advertiser was really looking for such a paragon as he describes, he would better gain entree to Heaven first off, for as a leading member of the chauffeur industry expressed it: "There ain't no such thing possible."

It would be illuminating to know if this advertiser ever considered what he was asking for. According to his advertisement, he wants an experienced driver. As a driver the applicant must be careful and safe. Under the beneficent Callan law, that is all attended to by the searching (?) examination to which the chauffeurs were subjected prior to being invested with the dignity of a license. If the man does not get panicky while driving twenty-five miles an hour he may be considered a safe driver. If he can go thirty miles an hour without cutting down an undue number of telegraph poles he may be designated a careful driver. It is of course understood that "if one can not be safe one might as well be careful." Careful drivers retail at about $30 per week. So much for the driving.

Then he must be an excellent mechanician, ready and able to make repairs and take care of a machine. It is to be assumed that a license granted by the sovereign State of New York presupposes some knowledge of the automobile, but where a chauffeur gets only $30 a week the question would be raised immediately: "How on earth are the garages going to break even if a $30 man really makes all the repairs himself?"

Naturally it is to be surmised that the advertiser intended to make some sort of monetary provision for mechanical repair work, in the shape of additional emolument to the chauffeur-mechanician—say $10 a week.

Then, this workman must be a willing laborer and hold himself in readiness to labor at all hours. He must be polite, neat, single and young. Middle-aged, married men are not to be considered no matter how neat and polite their domestic condition presupposes. Of course no married man could hold himself in readiness to work at any hour of the night or day outside of his own domain; nobody but reporters and Pullman car porters ever do that.

But listen! In addition to those other qualities, the applicant must have a fluent speaking knowledge of French, Spanish and English. Any man who has such knowledge of languages can pull down at least $25 a week tutoring. So up this stage the applicant ought to be good for at least $65 a week.

But now the conditions of the race begin to draw. Beside all the sterling qualities insisted upon in the foregoing, the advertiser states that this wonder among chauffeurs shall be able to act as valet. That ought to be worth at least $10 a week of any man's money. But hark! This chauffeur-mechanician-linguist-valet must be able to act as secretary to his employer. Now a secretary who is a secretary at all and not a blackmailing menace cannot be had under $40 a week at an inside tip-over figure. So all told the weekly insult to be handed to the successful applicant would now total $115 a week.

Just at the end of the advertisement it is stated that a knowledge of typewriting and stenography is to be desired in the applicant. Thus a dividing line may be reached by the advertiser in sorting out his flood of answers. All the chauffeur-mechanician-linguist-valet-secretaries who can work the typewriter and take short-hand dictation will be preferred over the chauffeur-mechanician-linguist-valet secretaries who are not so liberally endowed. If they are, the successful one ought to get at least $10 a week more, because a knowledge of typewriting and stenography is a merchantable asset and deserves to be paid for.

Finally this modest advertiser wants references.

The questions that immediately obtrude themselves are:

First—Is it possible for one single human being, and young at that, to have all the qualities, at any price?

Second—If there is such an individual, would he consent to work for any other human being alive?

Third—If he was found to exist and willing to work, how much would he be able to demand in the way of salary?

Fourth—If he agreed to go to work, being fully equipped according to specifications, how long would it be before his mentality, knowledge and remarkable qualifications would raise him vastly higher than the man who had the nerve to employ him?

Fifth—How he would shine in comparison with his employer?

But to get back to earth again. The leading members of the Professional Chauffeurs' Club of America, sober professionalists who are not in business for fun or for health, declare that the brain that conceived such an advertisement as appears above is fully capable of offering $20 a week for a duly qualified man. If the applicant accepts, the employer will get the worst of it; but he will never know, according to the clubmen.

What Two Polecats Had to Say

First skunk: "Say, Andy, what is that odor?"

Second skunk: "Why, Sam, don't you know?"

First skunk: "No, Andy; it beats all the smells I know of. What can it be?"

Second skunk: "Why, Sam, I am greatly surprised; don't you really know?"

First skunk: "Honest Injun, Andy, it beats me. What is it?"

Second skunk: "Why, Sam, that's the Callan automobile law."

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL CLIMBS, ETC.

Oct. 18	New York City, Madison Square Garden, Electric Car Day at the Electric Show.
Dec. 1	Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Dec. 31-Jan. 7, '11.	New York City, Grand Central Palace, Eleventh Annual International Automobile Show.
Jan 7-14, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Manufacturers.
Jan. 15-21, 1911	Detroit, Wayne Gardens, Detroit Automobile Dealers' Association.
Jan. 16-21, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4,'11.	Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories, Exclusively.
Feb. 6-Feb. 11,'11.	Chicago Coliseum, Tenth National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.
Mch. 4-11, 1911	Boston, Mechanics' Building, Ninth Annual Show, Licensed Automobile Dealers' Association.

Races. Hill-Climbs, Etc.

Oct. 6-8	Santa Anna, Cal., Track Meet.
Oct. 7-8	Los Angeles, Cal., Speedway Meet.
Oct. 8	Philadelphia, Fairmount Park Race, Quaker City Motor Club.
Oct. 14-18	Washington, D. C., Start of Washington Post Reliability Run to Richmond, Va.
Oct. 15	Long Island Motor Parkway, Grand Prize, Automobile Club of America.
Oct. 15-16	Philadelphia, Roadability Run, Automobile Club of Philadelphia.
Oct. 15-18	Chicago, Ill., Chicago Motor Club's 1,000-Mile Reliability Run.
Oct. 27-29	Dallas, Tex., Track Meet.
Oct. 28-29	New York City, New York "American's" Motor Truck Contest.
Oct	Exhibition Auto vs. Aeroplane, Dutchess County Fair, Poughkeepsie, N. Y.
Nov. 3-5	Atlanta, Ga., Speedway Meet, Atlanta A. A.
Nov. 5-6	New Orleans, La., Track Meet.
Nov. 10-12-13	San Antonio, Tex., Track Meet.
Nov. 24	Redlands, Cal., Hill Climb.
Nov. 24	Savannah, Ga., Road Race, Savannah Automobile Club.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

LET there be no mistake; the "Sixth Annual Vanderbilt Race" is the finishing touch to what has been a long-drawn-out struggle betwen the classes of cars that are made on a stock basis and the character of automobile that is specially made.

* * *

PROOF is now at hand that the special car is a nondescript; it is just what experience teaches that it must be, *i.e.*, the embodiment of freak ideas; expression of the man who thinks that an automobile must be a squawking rooster to be the "cock of the walk."

* * *

NOTHING can be plainer than the record as it stands; "despised" stock cars crowded each other at the finish; special construction automobiles went down before the onslaught, and were responsible for slaughter.

* * *

EVOLUTION, not revolution, wins. The stock car is the product of evolution; the special car is the instrument of revolution. Revolution beggars description; it has beggared the South American Republics; it will beggar the automobile makers who tolerate it, and it will thrice beggar the citizen who invests in one; nor does it matter whether it is a revolution that has the smell of burnt powder or one with the odor of partly burned gasoline.

DESTINY jokes with the joker; the wise purchaser, after witnessing the Vanderbilt Cup Race, will very properly decide that the stock car, as bad as the maker thereof thinks it is, is far better than the same maker's specially constructed car, on which he has wasted so much time and money that he is compelled to either perpetrate a fraud upon his own stockholders or pass the annual dividend.

* * *

WISDOM is a stowaway in the frock of cupidity; it is a strange brand of cupidity that is present when a maker of automobiles fits out his plant with special forms of machinery that will further the building of automobiles on a standard basis at a low cost, and then tries to beat his own good method; resorting to model-making in the process.

* * *

THINGS are not always what they seem. It is model-making when one model is hand-whittled; nor does it make any difference as to the shop in which the model is developed. Few models ever work satisfactorily; model-makers of the greatest competence invariably claim that models have to be put through a refining process to ultimately realize good results.

* * *

THE deceiver deceives himself. Instead of taking advantage of the refinements that naturally creep into a stock model as it is refined on a basis of necessity from year to year, the maker, not knowing his own business as well as one would reasonably expect that he should, thinks to do better, but, by a poorer way, and ends up by making the sad discovery that he is not even a good model maker.

* * *

WHEN railroad trains get off the track they go to smash; the same results accrue to the makers of automobiles when they risk their reputations in the keeping of poor special models instead of good stock automobiles. The makers with special models are bumping along the ties.

* * *

MODEL-MAKING should be confined to a small plant devoted to nothing else; when models are sufficiently revised and refined they have the qualities that belong in stock products. What chance is there then for a mere model in competition with a stock proposition?

* * *

FROM this time on purchasers of automobiles will shun special cars; they will know that they are crude models; it will be easy for them to appreciate the fact that it is in regularly made automobiles that habit lurks—the habit of accomplishing all that is good.

* * *

LOOKING backward affords the perspective necessary to convince man that improvements are wrought as time goes on. It is a little difficult, however, to discover any sign of improvement in the method that was adopted for the management of the Vanderbilt Cup Race. Perhaps the management was a little absent-minded; or maybe the investors wanted to get their money back

General Motors Finally Gets Support

$15,000,000 First Lien, Five-Year, Sinking Fund, Gold Notes, Issued—J. & W. Seligman & Co., New York, and Lee Higginson & Co., Boston, Underwriting the Issue.

Settles the Immediate Future of Twenty-one Component Automobile Companies, and Blows Away the Clouds That Threatened the Whole Industry for Several Months.

DEFINITE announcement of the financial plan adopted to solve the tangled problem of the General Motors Company was made late Wednesday afternoon, when it was officially stated that J. & W. Seligman & Co., of New York, and Lee, Higginson & Co., of Boston, had underwritten an issue of $15,000,000 6-per cent. first-lien, five-year gold notes based upon all the assets of the twenty-one component companies represented in the holdings of the General Motors Company. These companies are: Buick Motor Co., Cadillac Motor Car Co., Olds Motor Works, Marquette Motor Co., Cartercar Company, Oakland Motor Car Company, Rapid Motor Vehicle Co., Northway Motor & Manufacturing Co.. Elmore Manufacturing Co., Reliance Motor Truck Co.. Welch Company of Detroit, Weston-Mott Company, Randolph Motor Car Co., Welch Motor Car Company of Pontiac, Jackson-Church-Wilcox Co., Michigan Motor Castings Co., Champion Ignition Co., Michigan Auto Parts Co., McLaughlin Motor Car Co., Ltd., General Motors Company of Michigan, Oak Park Power Co.

The total issue authorized was $20,000,000, but the remainder not included in the terms of the underwriting may only be issued with the aproval of the company's finance committee which is to be nominated by the bankers.

The issue is designated positively as sinking fund notes. The assets of General Motors are estimated by the bankers at $37,383,000, about $12,000,000 of which is represented by real estate holdings and equipment of plants, subject to real estate obligations aggregating $266,500.

The funded debt and capital stock of General Motors, including the new issue, will be as follows:

$15,000,000 first-lien, 6 per cent., five-year, sinking fund, gold notes.

$17,835,400 7 per cent., cumulative, preferred stock, $2,800,000 of which is held by the company or its subsidiaries.

$20.835,030 common stock.

The Central Trust Company of New York has been designated as trustee, and mortgage notes and shares of stock of subsidiary companies securing the issue will be deposited under the trust deed which has been executed.

The majority of the stock deposited under voting-trust agreement will be voted by the trustees designated by the bankers to nominate a majority of the board of directors of the company within three weeks. This applies also to the subsidiary companies. Six out of seven members of the finance committee of General Motors and a comptroller for each of the component companies will also be selected.

The whole transaction simply means that the control of General Motors, with all it represents, has passed into the hands of a board of directors and a finance committee named by the financial interests who have underwritten the notes.

They will administer the properties for the next five years, and if at the expiration of that period the notes have been taken up, control of the property will revert to the present owners.

In the preliminary statement issued by the bankers, a most rosy view of the future of the company is taken.

To the trade, the settlement of the financial troubles of General Motors is of prime importance. The clouds that have beset that company for months have darkened the horizon of the whole business and the storm that has been averted by the consummation of this deal has been a very real menace to a number of companies not directly involved.

The talk of ruinous cutting of prices which has been heard at intervals recently will be stilled and the danger of the crumbling of a giant fabric, the falling of which must inevitably have buried dozens of companies in its ruins, has been averted.

In their statements to the public the bankers declare that the trouble with General Motors in the past year has been over-enthusiastic production and they assert that with conservatism as the keynote of the new régime, the business has a profitable future.

A damper was cast over the whole trade when it was announced recently that the Buick Motor Company, one of the largest of the members of the General Motors, was obliged to offer to sell one-year 6 per cent. notes at 85. This deal, which meant that the company would have to pay 21 per cent. for the use of money, is nullified by the huge underwriting plan that has been accepted.

It is planned to settle all outstanding obligations of the companies under the supervision of the new finance committee and then to provide a fund of at least $3,000.000 as working capital.

Flight at High Altitudes

BY MARIUS C. KRARUP. TRANSLATION AND REVIEW OF AN ARTICLE BY HENRY PETIT CONSIDERING EFFECTS OF ALTITUDE ON MOTOR AND AEROPLANE FUNCTIONS

ACCORDING to a fable dating back to remote antiquity the birds of the air once upon a time held a contest to determine which could fly to the highest altitude, and he was to be acclaimed as the king of their tribe. The eagle flew far up above the mountain peaks and none could follow him, but when he had reached as far as he could and surveyed all the rest far below a little tom-tit who had alighted on the eagle's back farther down, unnoticed, swung himself still a hundred feet higher into the atmosphere and chirped merrily, and he was chosen to be the king of fliers.

And this fable shows not only that altitude was considered a good test of flying ability long before the mechanical flier was invented, but also that tricks were counted good sport and that the originator of the fable had an instinctive understanding of the requirements, for he seems to have guessed that if the tom-tit had no real ability to compete with the eagle in thin air he could overcome this deficiency for a few seconds by saving his muscular power for one supreme effort. Fitness of the supporting surfaces, relatively small weight and relatively high power are the interchangeable qualities which enable the flier to rise into rarefied air, and, at least for all military purposes, these qualities, which also make for high speed, must determine the strategical superiority of one mechanical flier over another. If the dirigible balloon can be made dirigible indeed and can fly one thousand feet higher than the aeroplane—its worst enemy under war conditions—the latter will not be able to overtake it and harm it, though endowed with four times greater speed in the lower strata, and there will be room for both balloons and aeroplanes in whatever warfare may be necessary for preserving peace. The curious anomaly will then be witnessed of two kinds of war instruments, both effectively at work but neither able to injure the other, because one can get away horizontally and the other vertically.

But with regard to aeroplanes mutually the competition for instilling into them the ability to fly high must become as keen as the love for gold. No other quality, excepting only a perfected equilibrium, will be sought so ardently by constructors, since it will mean speed and safety, whether in peace or war, and will command the highest price for either purpose. And the competition will be saved from becoming a one-sided development of freakish machines by the necessity of preserving to the utmost possible extent the capacity for carrying the fuel for prolonged flights and a maximum of useful or warlike load. Having somewhat lightly set aside for the present the problem of equilibrium as one too difficult for immediate solution, the world of aeroplane constructors seem to have, as of one mind, comprehended the importance of altitude competitions and are straining their mental vision to perceive clearly the mechanical requirements for reaching great heights.

To this end it is, of course, necessary first to perceive what the effects of a rarefied atmosphere must be on each and all of the elements of an aeroplane machine. A synopsis of these effects is presented by H. Petit in *La Vie au Grand Air* for September 17 and, as an introductory to the study of the problems involved, this synopsis is reproduced in substance and with a few annotations in the following.

The elements and functions considered separately are: The motor, under which the carburetion, the compression, the ignition, the cooling, and the power; the propeller; the sustentation; the propulsion; the pilot.

The Motor.—The air's density diminishes with increasing altitude. At a height of 5,500 meters its specific gravity is reduced to one-half. The height record achieved by Chavez before his tragic death was already 2,600 meters. At this altitude the barometric pressure equals that of a column of 560 millimeters of quicksilver. To illustrate the problem, a pressure of 500 millimeters may be assumed which corresponds to a height of about 3,000 meters, a height which may now be reached almost any day. The normal pressure at the level of the sea is 760 millimeters; so the pressure at 3,000 meters is practically two-thirds of the normal. The effects of this reduction on the functioning of the motor may now be followed step by step from the entrance of a cylinderful of the rarefied air in the air channel of the carbureter until its exit through the exhaust tube.

Carburetion—The quantity of gasoline drawn in is practically a function not of the absolute pressure of the air, but of the difference in pressure above and below the jet. This difference and consequently the discharge from the jet will remain practically constant. But the mass of the vapor drawn in diminishes in the proportion of 3 to 2, and the mixture will therefore be too rich. This may be remedied by opening the additional air intake more widely, but in that case the automatic carbureter must be renounced. It is also to be noted that the effect mentioned is produced in equal measure when the gasoline is injected in liquid form. In all cases the discharge must be subject to regulation. (The fact that the lowered pressure will have the effect of depressing the gasoline in the jet might also be considered, as well as possible changes in the velocity of the air current. Possibly these factors have a tendency to maintain the quality of the mixture. But only definite and systematic experiments can probably settle these questions).

Compression—Suppose that the motor's normal rate of compression is 6 atmospheric pressures. The air admitted at 3,000 meters is no more at a pressure of 1 atmosphere and the final compression will be at the rate of 6 times 2-3 instead of 6 times 1; that is, 4 atmospheric pressures. By this reduction the efficiency and power of the motor are reduced to about 3-4 of what they were at the level of the sea, according to the accepted tables scheduling the effects of various rates of compression. A 50-horsepower motor will then from this cause alone be reduced to an output of 38 horsepower at an altitude of 3,000 meters. Only a motor whose compression may be varied at the will of the operator would remedy this effect, and none such has as yet been perfected, though it may shortly appear.

Ignition—The explosive mixtures burn so much more rapidly as they are more compressed. To get complete combustion when the compression is reduced it will therefore be necessary to vary the timing of the spark accordingly.

The explosion and the exhaust will apparently take a normal course, but the cooling of the motor will be affected.

Cooling—If air-cooling is employed, it seems that the motor will tend to heat up, as thin air will remove fewer calories than air of greater density. (At this point the heat loss due to radiation should really be considered as well as that due to convection). The effect of reduced heat convection should be so much more pronounced as the thermic efficiency is reduced from the other causes mentioned, leaving more waste calories to be carried away. On the other hand, the fuel charge is also somewhat reduced. An example will illustrate the proportions. Suppose the gasoline burned at sea level in a given length of time develops 100 calories and that the thermic efficiency of the motor is 30 per cent. There will then be 30 calories transformed into work, 35 carried away in the exhaust and 35 removed by the cooling air. At a height of 3,000 meters, if the carburetion remains normal through suitable provisions to this end, the burned gasoline will develop only 100 multiplied by 2-3, say 66 calories. The efficiency, reduced 1-4 by the diminished compression, will be 22 per cent. instead of 30 per cent. Hence only 14 calories out of the 66 will be transformed into work. There remain 52 calories, of which 26 will be passed with exhaust and 26 are to be carried away in the air. Will the motor heat? The answer is easy. At the sea level the air at normal density carried away 35 calories. At a density reduced to 2-3 it will carry away in proportion; that is, 23 calories, which is only slightly less than the 26 which should be carried away. (When radiation of heat is also considered it seems probable that even this slight deficiency arrived at by Mr. Petit will disappear.) If water cooling is employed the same reasoning applies, since the air after all remains the last medium for absorbing the surplus heat. But the lowered boiling point of water at high altitudes is to be looked out for.

The Power—With the mixture at its best proportions the fuel charge is reduced to 2-3, and the reduced compression further reduces the efficiency to 3-4. The motor having 50 horsepower at the sea level will therefore at an altitude of 3,000 meters have 50 horsepower multiplied by 2-3 and this again multiplied by 3-4; that is 25 horsepower. The power is reduced to one-half.

The most obviously suggested remedy would seem to be the use of an air compressor for supplying the carbureter with air at a constant pressure.

The Propeller—Working in a thinner medium, the propeller at any given speed of rotation will of course produce a proportionately weakened thrust, and a motor adapted to maintain its power at the increased altitude and well proportioned for its work at sea level will tend to run wild at the higher speed produced by the reduced resistance. A motor which will maintain its torque under these conditions must be one of the requirements. And a propeller with variable pitch or otherwise adapted for variable speeds suggests itself. (As referred to later, the resistance to propulsion diminishes in the same ratio as the propeller thrust, and, so far as mere speed is concerned, the altitude should therefore make little if any difference, but the work of the propeller is to produce sustentation also, and for this purpose an increased forward speed of the aeroplane is required, and this in some manner must be produced by the propeller and by the motor. Mr. Petit presents his version of the requirements in this respect).

Sustentation—Long calculations would be required for arriving at definite conclusions with regard to the influence of the rarefaction of the air upon sustentation and propulsion. (And then the results would be extremely doubtful for lack of experimentally ascertained data.) Only the direction in which the various forces will tend can be indicated. The sustentation may be looked upon as an action of the planes upon the molecules of the atmosphere. When the number of the molecules is reduced by rarefaction, either the planes must be held and balanced at an increased angle of incidence so as to act against as many molecules in a given time as at sea level, or the forward speed must be increased, this resulting partly in attacking an increased number of molecules and partly in attacking them, each of them, more vigorously. (Mr. Petit here assumes that the planes, as ordinarily constructed, attack a maximum of air molecules for a given plane area and also that they attack these molecules as vigorously as possible. He is interested in speed.) The increased speed is evidently the more interesting alternative, since there is always a loss in departing from the normal tilt. As sustentation is proportionate to the square of speed, at equal densities of the air, the speed required for converting a 2-3 sustentation into one full sea level sustentation must be the speed at sea level multiplied by the square root of 3-2, or approximately 1-2.

Propulsion—With the speed increased in this proportion, it is interesting to determine what the value of the drift or horizontal thrust will be. It is increased by the higher speed, but reduced by the smaller density of the air. The inert portions of the machine, such as frame, motor and aviator's body, offer less resistance than at sea level. On the whole it seems that the drift, so-called, should remain about the same.

Summarizing at the high altitudes the power of the motor is reduced; to obtain support one must increase either the speed or the tilt and the propeller must turn more rapidly. A motor disposing over an excess of power is therefore indispensable so much more as the work expended in rising is far from being negligible. (The logic of this inference in favor of higher power does not seem clear. Even the power to rise is required as much near sea level as at greater heights. But the reasoning is an example of that which passes current at present in favor of high motor power. An excess of power is of advantage at all altitudes if it may be obtained without sacrifice at other points, but the author has scarcely shown that it is power which is required for producing the indispensable increase of speed in the thinner air. He has shown that the ordinary motors lose part of their power in the thinner air and that something must be done to obviate this loss. The increase of the original motor power represents only the readiest method for having enough power left after the loss is sustained).

The rise of an aeroplane weighing 500 kilograms, with everything on board, from sea level to a height of 3.000 meters necessitates an expenditure of 1,500,000 kilogrammeters of energy, and if the apparatus rises to the height mentioned in one-half hour not less than 11 horsepower is employed for rising only, representing a power requirement to be added to that necessary for propulsion and sustentation. (But for rising at the same rate to a height of only one thousand feet the same additional power is wanted. The difference is only one of the continuity of the effort).

The Pilot—Finally the flights at high altitudes already made by Chavez and others have shown that it is necessary to consider in the first line the influence of rapid changes in the density of the atmosphere upon the aviator, physically and mentally. With the reduced pressure from the outside the gases dissolved in the blood and contained in the vessels of the body tend to escape, and this tendency often causes grave troubles in the circulation, well known under the name of mountain fever and similar to those experienced by divers suddenly rising to the surface after working at considerable depths.

Recent Events Among Aviators

Arthur Brookins started in a Wright biplane from Chicago at 9:15 a. m., Sept. 29, descended at Gilman, Ill., 75 miles from Chicago, at 11:43 a. m., resumed flight at 12:41 p. m., descended at Mount Pulaski, 88 miles further, at 3:30 p. m., repaired a broken pump, ascended again at 3:48 and arrived at Fair Ground, Springfield, Ill., at 4:25 p. m., having covered a distance of 187 miles in all. The machine was provided with starting wheels, one of which was broken when the aviator made the ascent from Mt. Pulaski.

The French ministry of war offers to pay a premium of $20,000 to the constructor who furnishes an aeroplane capable of carrying a useful load of 300 kilograms at a speed of at least 60 kilometers per hour in a continuous flight of at least 300 kilometers. Competitors must sign a contract and are allowed $100 extra for every mile of average speed attained in excess of the minimum. In addition to the $20,000 premium the successful constructor receives an order for 20 aeroplanes of the same type at a price of $6,000 for each. If the State selects to manufacture the 20 aeroplanes by means of its own facilities, it will pay the constructor a royalty of at least $600 for each apparatus with an additional bonus for excess speed.

The number of entrants who are expected to start in the projected race from Chicago to New York has now been reduced to three, which is the minimum according to the rules laid down by the newspapers offering the prize of $25,000 for the successful completion of the flight. The three who still propose to try are Charles Foster Willard, J. A. D. McCurdy and Eugene B. Ely. The start is to take place from Hawthorne race track near the Indiana line at 10 a.m. on Oct. 8, if the weather permits, and the voyage must be completed by Oct. 15.

Fairmount Park Field Big

THIRTY CARS WILL FACE THE STARTER ON SATURDAY NEXT—PRELIMINARY PRACTICE SHOWS COURSE IS FASTER THAN EVER

PHILADELPHIA, Oct. 4—Now that the Vanderbilt Cup race is over interest centers in the Fairmount Park road race next Saturday, and it promises to be the greatest ever held over that historic course.

The entries for the race came in with a rush on Monday—two Nationals, two Stoddard-Daytons, Mercedes, Mercer, two Marmons, Simplex, Corbin and three Abbott-Detroits. With a field of thirty and the course faster this year than in the two preceding years, not only the record for the entire course, but the record of 8 minutes 47 seconds, for a lap, made last year by Len Zengle in a Chadwick car, should be broken.

There were about 5,000 persons out at sunrise Monday, the first morning scheduled for practice, and six drivers sped around the eight-mile course until 7:30, at which hour trials must stop. Being the first time, the drivers didn't cut loose and there were no speed thrills.

Every effort is being put forth to safeguard the public and the contestants and every precaution will be taken and ropes drawn on each side of the course and no one allowed to stray on the road. Similarly, a policeman is stationed at each entrance of the park to prevent the entrance of any vehicle between 6 and 7:30 a. m. This will be the rule throughout the week.

Instructions for contestants have been issued and cars will be examined for piston displacement Wednesday after practice.

Policing arrangements have been completed. Three thousand men, an average of one to every 100 feet, will be on guard and no one will be allowed to cross the track from start to finish. With the assurance of a clear track and with the improved conditions of the road a new record for the course is confidently anticipated. Parking places, boxes and seats are selling at a rapid rate, and there are indications that the beneficiaries of the proceeds, all of which go to charity, will derive a greater amount than at any of the preceding contests.

Beginning Monday morning the course will be open for practice from 6 till 7:30 a. m. every day. These early morning spins are a great source of interest in themselves, and have always attracted crowds of spectators. List of entries follows:

No. Car	Entrant	Driver
2—Chadwick	Chadwick Eng. Works	Lew Zengle
3—Chadwick	Chadwick Eng. Works	Al Mitchell
4—Benz	Benz Auto Import Co.	Irwin Bergdoll
5—Benz	Benz Auto Import Co.	Ed Hearne
6—Apperson	Apperson Bros. Auto Co.	H. M. Hanshue
7—Jackson	Jackson Auto Co.	E. F. Scheiffler
8—Cole "30	Cole Motor Car Co.	"Bill" Endicott
9—Cole "30"	Cole Motor Car Co.	Harry Endicott
10—Simplex	J. Fred Betz, 3d	Mr. Betz.
11—Simplex	John Megraw	W. C. Mullen
12—Ford	Ford Motor Co.	F. Kulick
13—Benz	Al Hall	Al Hall
14—Benz	C. A. Bergdoll	C. A. Bergdoll
15—Marmon	Nordyke & Marmon Co.	Harroun
16—Marmon	Nordyke & Marmon Co.	Dawson
17—Stoddard-Day.	Stoddard-Dayton Auto Co.	H. N. Harding
18—Stoddard-Day.	Stoddard-Dayton Auto Co.	T. De Hymel.
19—Mercedes	Mr. Jagersberger	T. J. Wosser
20—National	National Motor Car Co.	Aitken
21—National	National Motor Car Co.	Wilcox
22—Mercer	Mercer Motor Car Co.	H. Frey
23—Simplex	Robt. E. Hitemeyer	R. Beardsley
24—Corbin	Corbin Motor Vehicle Co.	Joe Matson
25—Abbott-Detroit	Abbott-Detroit M. C. Co.	....

Records Go at Winnipeg Meeting

WINNIPEG, Oct. 3.—New records for 1 and 25 miles were hung up here Saturday for the Dominion of Canada, at the fourth annual meet of the Winnipeg Automobile Club.

W. C. Power, in a McLaughlin-Buick "40," lowered the Canadian mile track record to 59 seconds, and in the Dunlop Trophy race of 25 miles he covered the distance in 25 minutes, 19 1-5 seconds. Owing to the number of entries in the last race, he was forced to keep entirely to the outside of the track, thereby covering more than the distance. His speed in this event was better than a mile a minute for the distance. The summary:

No. Car	Driver	Time
Dunlop Trophy Race, Twenty-five Miles—		
1—McLaughlin-Buick	W. C. Power	25:19
2—National	W. Guest	26:24
3—KisselKar	A. Moore	
One Mile Time Trial—		
1—McLaughlin-Buick	W. C. Power	:59 1-5
2—National	W. Guest	1:01 4-5
3—Knox	R. Husk	1:03
Five-mile Motor Cycle Race, Open—		
1—Indian, 7 h. p.	J. Baribeau	5:25
2—Indian, 5 h. p.	Burgess	
Five-mile race for cars up to 160 cubic inches—		
1—Maytag	Harn	6:25
2—McLaughlin	Cline	
Ten-mile race for cars from 161 to 230 cubic inches—		
1—Warren-Detroit	D. A. Brown	12:40
2—McLaughlin	J. Cline	
3—Maytag	Harn	
Ten-mile race for cars from 231 to 300 cubic inches—		
1—McLaughlin-Buick	W. Guest	11:19
2—Warren-Detroit	J. Brown	
3—Knox	Houghton	

Correction

In a recent issue of THE AUTOMOBILE it was made to appear that Velie car, Number 51, which took third place in the free-for-all at the Algonquin hill climb, was driven by Cooney. It appears that through a transposition in the program, the car carded to be driven by Cooney was driven by J. H. Stickney.

Accident Spoils Springfield Races

SPRINGFIELD, Oct. 3—The race program at the State Fair was sharply abridged Saturday afternoon by an accident in which Larue Vredenburgh, president of the Springfield Automobile Club, was killed while driving in competition.

The summary of events that preceded the mishap is as follows:

Car	Driver	Time
Five-mile race for fully equipped stock cars driven by amateurs—		
Jackson	Bisch	5:42
Stoddard-Dayton	Vredenburgh	
Chalmers-Detroit	Hicks	
Ten-mile race for cars under 600 cubic inches displacement—		
Falcar	Hughes	10:28 3-5
Cutting	Slagel	
Stoddard-Dayton	Vredenburgh	
Five-mile race for stock chassis of from 231 to 300 cubic inches		
Falcar	Hughes	5:15
Buick	Farr	
Staver-Chicago	Cheney	
Ten-mile race for stock chassis of from 161 to 230 cubic inches		
Buick	Farr	10:24 2-5
Staver-Chicago	Mounckmeier	
Chalmers-Detroit	Hicks	
Five-mile race for gasoline cars of from 301 to 450 cubic inches		
Falcar	Hughes	5:14
Buick	Slagel	
Stoddard-Dayton	Vredenburgh	
Ten-mile race for gasoline cars of from 451 to 500 cubic inches		
Knox	Oldfield	9:59 3-5
Stoddard-Dayton	Vredenburgh	
Jackson	Ellis	
Ten-mile free-for-all—		
Darracq	Kirscher	9:51
Hudson	Hickox	
Moon	Wells	
Five-mile free-for-all—		
Falcar	Hughes	5:13 2-5
Cutting	Tower	
Staver-Chicago	Cheney	
Australian pursuit race for cars under 600 cubic inches—		
Hudson	Hickox	Winner
Twenty-mile race for stripped stock chassis—		
Falcar	Hughes	20:03 3-5
Jackson	Ellis	
Moon	Wells	
Knox	Oldfield	

Good Roads Convention

THIRD ANNUAL MEETING IN ST. LOUIS A GREAT SUCCESS—MANY APPROPRIATE PAPERS READ AND DISCUSSED—ATLANTA NEXT CONVENTION CITY

ST. LOUIS, Oct. 3—Nearly 400 delegates from two-thirds of the States in the Union attended the Third Annual Good Roads Convention at the New Coliseum Wednesday, Thursday, and Friday.

Officers and delegates pronounced the gathering the most successful of good roads meetings. Atlanta, Ga., was selected as the next convention city.

The delegates were welcomed at the opening session by Governor Herbert S. Hadley, of Missouri. He pledged himself to the good roads movement and promised to use his official influence in aid of increased appropriations from both the State and Federal governments.

The official program at the first day's session was not followed. Charles D. Ross, of Newtcn, Mass., advocated legislation giving the automobile the middle of the road, with horse-drawn vehicles at either side.

A course of instruction in the public schools relative to the danger of children playing or walking in roads was advocated. "Convict Labor in Public Road Construction" was the title of a paper read by Joseph Hyde Pratt, State Geologist, of North Carolina. Major W. W. Crosby, of Baltimore, talked on "Modern Road Construction."

At the second day's session Prof. Arthur H. Blanchard, of Brown University, attacked the American system of permitting city or county engineers to lay out and build roads and then to leave their care in the hands of a different set of officials. Roads should be built and maintained by the same department, he said.

George R. Carter, of Marlin, Tex., told how the commercial bodies of that State organize tours of troupes consisting of six or more motor cars, carrying a complete moving picture show with thousands of feet of films, to be used to demonstrate the benefits to be secured by good roads. Harold Parker, chairman of the Massachusetts Highway Commission, criticised the system of supervising road building in his paper on "State Roads to Meet Modern Traffic Conditions." The list of papers read before the convention the second day included "High Altitude Roads," by F. L. Bartlett, Denver; "Treatment of Earth Roads," by D. Ward King, Jefferson City, Mo.; "Across Missouri Highways," Curtiss Hill, State Highway Commissioner of Missouri; and "Crest of Blue Ridge Highway," Joseph Hyde Pratt, Chapel Hill, N. C.

At the closing session the convention passed resolutions condemning poll-tax road labor.

This National Convention Committee was selected: George C. Diehl, Buffalo, N. Y., chairman A. A. A. Good Roads Board; N. J. Bachelder, Concord, N. H., Master National Grange; Charles S. Barrett, Union City, Ga., president Farmers' Union and Co-operative Association; Logan Waller Page, Washington, D. C., Director United States Office of Public Roads; L. H. Kittredge, Cleveland, President National Association of Automobile Manufacturers; R. D. Chapin, Detroit, chairman N. A. A. M. Good Roads Committee; Alfred Reeves, New York City, General Manager Association Licensed Automobile Manufacturers; Harold Parker, Boston, State Highway Commissioner of Massachusetts; Fred Atwater, Bridgeport, Conn., President American Wheelmen; C. J. Butler, Detroit, Motor and Accessory Manufacturers; S. Percy Hooker, Albany, N. Y., State Highway Commissioner of New York; Lewis R. Speare, Boston; Robert P. Hooper, Philadelphia; A. G. Batchelder and Charles Thaddeus Terry, New York.

Philadelphia Club Arranging Tour

PHILADELPHIA, Oct. 3—The fall tour of the Automobile Club of Philadelphia to Atlantic City and return, over entirely new route, will take place Saturday and Sunday, October 15 and 16.

The itinerary of the trip calls for a run of 126 miles the first day, from Philadelphia through Salem, Bridgeton, Port Elizabeth, Tuckahoe to Atlantic City, and a return journey of 86 miles through the Jersey pine lands. The entries already received are as follows:

No.	Car	Driver
1	Chalmers	Harvey Ringler
2	Jackson	Ira L. Brown
3	Cadillac	Henry Shock
4	Franklin	George Karlavghan
5	Winton	Paul M. Elsasser
6	Marmon	Joseph Hudson
7	Stevens-Duryea	Frank W. Hitchcock
8	Stanley	Frederic Wilcox
9	Cutting	Mrs. Charles A. Wolf
10	Marion	Allan Lund
11	Premier	H. E. Grant
12	Welch-Detroit	Edward Wilkie
13	Franklin	....
14	Premier	Carl Zentmayer
15	Buick	Edward Wilkie
16	Pierce-Racine	S. Walter Harper
17	Locomobile	Howard McTurk
18	Pullman	W. C. Longstreth
19	Stanley	D. W. Harper
20	Mitchell	W. J. Vogler
21	Stevens-Duryea	F. W. Eveland

Grand Rapids to Have Auto Show

GRAND RAPIDS, MICH., Oct. 3—Grand Rapids' second annual automobile show probably will be held February 15 to 18 inclusive. This is the week following the big Chicago exhibition. As was the case last year, the show will be under the auspices and management of the Grand Rapids *Herald.*

Correcting a Wrong Impression

It was erroneously stated in some of the *newspapers* on September 29 that the Emil Grossman Co. will go into liquidation and wind up its affairs. There is no foundation in fact for this statement. The real situation is that the Eagle Co. of Newark, N. J., has taken over the wind shield and spark plug business of the Emil Grossman Company, and Emil Grossman is now sales manager of the Eagle Co., with headquarters at his old stand, 232 W. Fifty-eighth street, New York, where he is carrying on the business of the Emil Grossman Company, independent of the part of the business that was taken over by the Eagle Co. It will be remembered that Emil Grossman held a large interest in the Motor Car Equipment Co., which interest, as he now states, has been disposed of. Referring to the Eagle Co., which is controlled by the Standard Co., of Torrington, Conn., it is preparing to do business in a very large way with the Red Head spark plug and the wind shield enterprise as formerly carried on by Emil Grossman, utilizing the large building in Newark which was formerly occupied by the Domestic Sewing Machine Co. This plant is being fitted out in o most comprehensive way with the necessary special tools and equipment for the making of accessories.

Schacht Company Extending Plant

The Schacht Motor Car Company, Cincinnati, is building a new factory. The building is to be 500 feet long by 70 feet wide and three stories high. It is being constructed of buff pressed brick and will have offset boiler and engine rooms. Its cost will be $100,000 without equipment.

Vanderbilt Race Analyzed

The Vanderbilt Race by Laps

The race was started at 6 o'clock, National No. 1, driven by Livingston, leading the way. Oldsmobile No. 5 broke an oil pump before the start and did not appear on the line. All the cars got away in good shape except Marquette-Buick 29, L. Chevrolet, which stalled its motor just after passing the line. The first car to complete the round was Lozier 2, but it was not in the lead on a basis of elapsed time. Marquette-Buick 29, despite its mishap at the start, was pushed through the lap in 10:46, the fastest time ever made for a first lap under the circumstances. Knox 32 was second in 11 flat and the other two Marquette-Buicks were tied for third and fourth places, 3 seconds behind. Columbia 12 went out before the end of this round through a skid from a bridge caused by a bursted tire.

Lap 2—All of the cars remaining in the race completed the second lap, except the Royal Tourist, which broke a camshaft and retired. Marquette-Buick 29 held the lead with its stablemate, 27, in second place, and the Knox 3 close on their heels. Marmon 25, Alco 18 and Lozier 2 followed in close order. The Jackson 19 was reported with a broken rod somewhere up the stretch. The leaders were all driven at a terrific clip.

Lap 3—There was no change in the order of the first three

OFFICIAL TABLE SHOWING THE TOTAL AND LAP TIMES OF EACH OF THE THIRTY CARS THAT

STORY OF THE RACE BY LAPS, WITH TABLES SHOWING AT A GLANCE THE PERFORMANCE OF THE CARS IN THE THREE EVENTS

cars in this round, but the Lozier and Marmon 25 hung a trifle and the gap between them and the leaders was widened somewhat. The Alco made no effort to keep pace with the pacemakers, maintaining a steady rate of speed, about a minute slower for the round than the pathfinders. Marmon 21, Harroun, crossed the tape for the first time, having experienced mechanical troubles soon after the start.

Lap 4—The Knox went out in this round from valve troubles, leaving 28 cars in the race. The place of the Knox in the procession was taken by Marmon 25, while the Lozier and the two Pope-Hartfords trailed along in close company. They were all drawing away from the carefully driven Alco, the leader being over 4 minutes ahead.

Lap 5—Marquette-Buick 29 quickened the pace in this round and slipped away 49 seconds from the flying Marmon. It was followed in its spurt by its stablemate. The leader made the round in 10:21.

Lap 6—This circuit saw the last of Benz 8, Heim, as the car caught fire from a leaky gasoline channel and was retired. The order of the leaders was not changed.

Lap 7—The American 23 succumbed in this lap, a cracked cylinder putting the car out of the running. There were 26 cars

officially left in the contest. No change in leading positions.

Lap 8—The first of the Marquette-Buicks went out in the eighth circuit when car No. 3, driven by Arthur Chevrolet, experienced trouble with its transmission and retired. Marquette-Buick 29 averaged nearly 74 miles an hour up to this point and was almost 7 minutes ahead of the Alco.

Lap 9—The heart-breaking speed at which the pacemaker had been driven from the start began to tell upon the car in this round, and at the tape it was found that it had not only lost the lead, but had fallen back to seventh place. The Alco showed prominently in the contest for the first time, finishing the round in third place, being led by Marquette-Buick 27 and Marmon 25.

Lap 10—One round proved enough for Marquette-Buick 27, which went out with radiator troubles. The Corbin contestant also dropped out with similar troubles, thus leaving 23 cars in the race. Marmon 25 assumed the lead by a wide margin, having over 4 minutes the advantage of National 31, which had been pushed forward rapidly by Disbrow. Marquette-Buick 29 was driven hard to make up lost distance and was in third place, less than 1-2 a minute behind the National. Lozier was fourth and Alco fifth, all within striking distance.

Lap 11—The Marmon increased its lead slightly in this round, gaining 35 seconds on the National and 15 seconds on the Marquette-Buick.

Lap 12—The leader made slow time in this circuit on account of tire changes, but at the tape the Marmon 25 still led by 48 seconds over the Marquette-Buick 29, which was bowling along desperately to get to the front. National 31 avoided the spurting and fell back into third place.

Lap 13—This proved to be one of the speediest of the whole race. National No. 10 made a wonderful rush, breaking all records for the course in 9:31. The Alco's driver took no chances, however, and made the round in 11:27.

Lap 14—The pace of the last lap proved to be the last straw for several of the competing cars, and at the conclusion of this round the steadily moving Alco had moved up to third position, behind National 31. Marquette-Buick 29 made slow time and was apparently out of it. In its fourteenth circuit Marmon 21 broke a shaft and went out.

Lap 15—National 31 fell back several pegs with a round in 15:47 and the Alco moved up to second place, 2:24 behind the Marmon. National 10 slipped into third position, about 3 minutes back of the final winner. The Simplex pair, who had been maintaining a steady, fast pace from the start, were closing in with Pope-Hartford 17 a few seconds back.

Lap 16—The Marquette-Buick found its finish in this lap through an accident on the back stretch, in which the car was practically demolished. National 10 narrowed the lead of its rivals a small shade in this round, but the relative positions were unchanged.

Lap 17—The Marmon, tin-canning along in front, apparently established a winning lead at the end of this round, gaining 1:36 on the Alco and 12 seconds on the National 10, which was close on the latter's heels.

Lap 18—The Marmon lost the cup and prize in this round through hitting a spectator and losing about 8 minutes in the circuit. When the contenders had slipped over the tape, the Alco was in front with a margin of 3:24 ahead of National 10, which was 33 seconds before the former leader.

Lap 19—Out in front for the first time, Grant took hold of his car and made the next lap in 12:54, allowing both the placed cars to crawl up close.

Lap 20—The Alco was driven fast in this lap to maintain its narrowing lead, but the little Marmon was shooting at the big black car and cut off 7 seconds of the margin that separated them. National 10 fell back into third place in this drive. The Marmon was only 2:13 behind at the tape and was going fast.

Lap 21—A tire change for the Alco practically wiped out its lead in the next to the last round, and the Marmon, running nearly as fast as it did in its best lap. cut another minute and 30 seconds from the lead.

Lap 22—Into the stretch 18 great road locomotives plunged for the final trial of speed in competition for the cup. In front was the black car that had made such a gallant fight. Its 6-cylindered engine was working like a watch; its pilot, whose great headwork had proved a big factor in the race, was as steady as his car. Next behind was the Marmon, and next came a National, then another National, a Lozier—all stock cars, the special racing machines having been eliminated for one cause or another, and they were hopelessly beaten at this stage.

National 10 was the first to appear at the head of the stretch, and Aitken shot over the line in 257:29. He had done the last lap in 11:26, and barring disaster to the leaders, this was not fast enough to win. Then came a pause of a few seconds and the Alco plunged over in 255:58, making the last lap in 11:22. If the Marmon could make the final round in 10:40, it would win. The seconds ticked off slowly in the Alco camp, but before the yellow jacket showed at the head of the stretch somebody threw his cap in the air and yelled triumphantly. Then the staunch Marmon appeared and flashed past, but it was almost 25 seconds too late to gain first honors.

"Among Those Present"

W. C. Durant, of the General Motors Company, proved a life saver to some members of the press. Mr. Durant furnished them with a Welch-Detroit which was used in preliminary work.

The Pope-Hartford contingent was down from Hartford en masse. Among others there were Colonel George Pope, C. H. Gillett and Harold Pope.

J. D. Fulton, of the *Record-Herald,* and Joseph E. G. Ryan, of the *Inter Ocean,* were among the Chicago delegation.

James Evans, advertising manager of the Brush Runabout Company, came in from Detroit on Friday.

F. E. Dayton and H. V. Nuckols headed the Columbiaites.

Harry Field, of the Hartford Rubber Works, was among the interested spectators.

Mr. Brand, of the Parish Steel Company, of Reading, Pa., was present.

Orlando Weber, of the Chicago Palmer & Singer branch, with Mr. Singer, was on the track from an early hour.

C. G. Bleasdall, manager of the Maxwell-Briscoe-Cleveland Company, was a guest of Messrs. Briscoe and Maxwell.

Frank Briscoe, of the Brush Runabout Company and the Briscoe Manufacturing Company, with his family and some friends also occupied a box.

Howard Marmon was in charge of the Marmon pit. Howard prefers to be in the midst of the battle.

Harry Strong, president of the Rochester Automobile Club, who has lately gone into the automobile industry, drove down.

Charles L. Stevens, formerly with the Los Angeles Motordrome, was quartered at the Garden City Hotel.

William J. Lasher, well known in New York trade circles, announced prior to the race that he had assumed charge of the Hartford branch of Carl H. Page & Company.

William J. Coghlan, manager of the Chadwick Engineering Works, Philadelphia Branch, was one of the interested visitors.

John N. Willys, president of the Willys-Overland Company, was a keenly interested spectator.

H. A. Wilcox, manager of the Kelly Motor Truck Comapny, of Sprngfield, O., saw the race.

Inadvertently Let Cat Out of the Bag

Les vaincus, ce ne sont pas ceux qui ont couru, mais ceux qui se sont abstenus.—*La Vie Automobile*, Sept. 24, on results of "La Coupe des Voiturettes."

(Translation):

The conquered are not those who raced but those who held aloof.

This is one of the points that was plainly brought out in the Vanderbilt race—foreign automobiles were few and far between.

Short News From Everywhere

ITEMS CULLED HERE AND THERE FOR QUICK READING—TRADE AND GENERAL INFORMATION

—W. A. Logan has recently been added to the sales force of the Cleveland Rauch & Lang Co.

—George L. Schofield has been made general manager of the Elkhart Motor Car Company, succeeding John T. Knott.

—E. Winkes, formerly with the Cleveland Rambler branch, has accepted a position with the firm selling Maxwell and Columbia cars.

—The Halladay line, consisting of sixteen models, will be handled on the Pacific Coast by the Halladay Motor Car Company at Los Angeles.

—Hughson & Merton, Pacific Coast representatives of Ajax tires, have moved into a new store in Seattle, Wash., corner Pike street and 10th avenue.

—The Cleveland Electrical Repairing Company has opened a storeroom at 2025 East 22d street. Manager F. H. Clark was manager at the Peerless factory for six years.

—The Maxwell entry was awarded the reliability cup in the second annual contest of the Louisville Automobile Club. A Cole "30" proved winner in the economy division.

—Announcement has been made by S. F. Edge, Ltd., of London, that the company's exhibit of two Napier six-cylinder cars had been awarded the Grand Prix at the Brussels Exhibition.

—The Vail Motor Car Company, agent for the Empire and Clark lines, has purchased the Raymond garage on Carnegie avenue, where it will continue the garage and add a large repair and machine shop.

—S. A. Zapp has purchased the Lawrence Garage at 124 E. Fourth street, Fremont, Neb. The Overland agency will be continued and another line added. Supplies and accessories and a well equipped repair shop will be maintained.

—F. E. McClure, manager of the branch house that will be opened by the Brush factory this week, will also handle the Alden-Sampson truck. McClure has already began to make arrangements for salesrooms and northern Ohio agencies.

—At a meeting of the Board of Governors of the Columbus (Ohio) Automobile Club Dr. Walter E. Ranchous was elected secretary to fill the vacancy caused by the resignation of Arthur M. Crumrine and Frank McMakin was elected assistant secretary.

—J. B. Sperry, well known in Cleveland automobile circles, agent for the Henry car, has been appointed manager of the Warren Auto Sales Company, the Cleveland branch house for Warren-Detroit cars. Three hundred cars have been allotted Cleveland and northern Ohio.

—Dr. A. T. Lawless, of Syracuse, won the Syracuse *Herald's* second annual sociability run to Renwick Falls and return last week with a Maxwell car. Three other prizes were awarded for finishing the course close to the secret time. This is the second time Dr. Lawless has won the cup.

—The Cartercar Company has completed arrangements for opening a branch in Chicago. A lease has been closed for a handsome showroom at 324 Michigan avenue. Charles E. Hammerly, who has had the agency for the Cartercar for many years in Chicago, and owns a garage at Harrison and Oakley boulevards, has been named as branch manager.

—The Columbus Buggy Company of Columbus, Ohio, is sending out catalogs showing the various models made by the company for 1911. Photographs of the 10 models of gasoline cars are shown and the distinguishing features are explained in full.

—On the point of going to press it is reported by wire from Detroit, Mich., that the E-M-F Co. has dropped the prices of its 30-horsepower E-M-F from $1,250 to $1,000 and the 20-horsepower Flanders from $750 to $700. The reasons attributed for these reductions are improved facilities of manufacture and reduced cost of materials owing to the purchase thereof of large quantities.

—President Walker, of the Lorraine Motor Company, has closed a contract with the Philadelphia Housewrecking Company for the clearing of a large plot at Thirty-seventh and Ludlow streets, upon which a model garage will immediately be erected. All the appurtenances of a first-class club will be included in the equipment of the second floor, which will include apartments fitted up for ladies on one side of the new building, a suite of rooms for men on the opposite side, and a reception room leading to the main floor. Eighty cars will be stored in the building. A large machine shop equipped for heavy automobile work will be one of the features of the plant. In this field the Pierce-Racine and the Allen-Kingston are the cars which the Lorraine Motor Company will handle. The officers of the company are: W. L. Walker, president; Joseph Booth, vice-president; E. More, treasurer; J. L. Larsen, Dr. Ruel Stewart, Joseph Booth, George T. Cutler and W. L. Walker, directors.

Great Western Has New Home in Boston

The illustrations here given are of the new garage which was just completed by the Castle Square Garage Co., Boston, Mass. It is an L-shaped building fronting upon Ferdinand street, running through to Edgeley street. The group of illustrations show the front and rear façades and two interior views. As will be observed the building is of concrete construction faced with brick, and besides affording a large floor space entirely devoid of obstructions the building is light and is fitted out with every convenience, including three turntables, wash racks with hot and cold water, and a place for everything. The Great Western "40" is all that will be handled at this establishment and the sales rooms are so arranged that the cars may be examined closely by the clientèle of the company.

New Castle Square Garage, Boston, Mass. The home of the Great Western "40"—It is a fire-proof building with every convenience and has well-appointed salesrooms

Prominent Automobile Accessories

ACETYLENE STORAGE AND TRANSPORT

Among high powerful illuminants that are easy to handle and relatively cheap and portable acetylene gas certainly holds its own. Generators for direct gas production on the car or boat are extremely useful, but have their drawbacks owing to the necessity of recharging frequently unless they are bulky and cumbersome. There is also to be taken into consideration the storage of loose carbide and the chance of clogging and stopping of the water flow.

In order to obviate these small inconveniences much attention has been paid to dissolved acetylene put up in cylinders that are easy to handle besides being clean. The difficulties attending the compression of the gas into containers, due to the peculiar chemical character of acetylene, at the outset caused several failures. When certain temperatures and pressure limits are exceeded spontaneous decomposition takes place.

It is necessary to dissolve the gas in suitable organic solvents of the highest purity held in containers packed with porous material in such a way that no pockets can form inside.

A convenient and safe method of carrying acetylene gas has been placed on the market by the Searchlight Gas Co., of Pittsburg, Pa., and Warren, Ohio. The cylinders used are stamped from high-grade steel and measure 22 inches long and 6 inches in diameter, when finished. Protection from blows is well guarded against by placing the gauge, valve, safety plug and safety diaphragm entirely within the recess shown in Fig. 4, which also shows the compactness of the whole apparatus. The head is fitted after the porous filling has been inserted and carefully brazed, insuring the absence of all leaks. The strength of the cylinder is several times the pressure at which it is fully charged.

Fig. 1—New tire pressure gauge

Fig. 2—New tool for valve-grinding

In Fig. 3 a fusing plug is fitted "E" which melts at a very low temperature, allowing a gradual release of pressure in case the tank comes in contact with great heat. In case of accident the safety diaphragm D releases at 400 pounds pressure.

HANDY TIRE PRESSURE GAUGE

Sufficient stress cannot be laid upon the necessity of owners to see that the correct pressure is maintained in the tires and to do this it is essential to have a gauge that correctly registers this pressure. In the Brown Tire Pressure Tester, made by the Brown Co., Syracuse, N. Y., it is possible to ascertain the amount of pressure the tire contains by removing the valve dust cap and firmly pressing the tester on the nipple. Two hands are fitted, one to register all pressures and this carries with it another hand to register the maximum amount in the tire; this latter hand is red and remains at the maximum point of pressure, enabling the reading to be taken after gauge has been removed from the tire.

VALVE GRINDING TOOL

Motorists can save themselves money in the long run if they provide their men with a few extra tools to render certain operations on the car easier. One duty that the man often shirks is the regular grinding of valves. A device that permits the merest tyro to effect the operation as well as the experienced mechanic will be found in the valve-grinding tool here shown. It is made by the Brown Company, of Syracuse, N. Y.

NON-CORROSIVE BURNER SUBSTANCE

Next to a good automobile comes the question of lighting, for then the car is capable of affording a double time of service, since it will be available for use in the night time as well as during broad daylight. Autoists of experience have struggled with the problems of illumination, and acetylene has proven to be of great efficacy, despite the little drawbacks that attend its use. One of the real advances in the direction of the perfection of acetylene lighting comes in the form of Nuremberg Steatite, which is the material used in Alco Burners, one of which is here illustrated. It is of course true that the scientific shape of the burner has much to do with the excellent service it renders, but it is a property of this steatite to serve for a long time without choking up, and it is claimed that the real secret attending this latter consideration lies in the non-corrosive qualities of the steatite. These burners are made in many varieties to suit the several conditions, but the particular one here illustrated is known as the "Hilo-de-luxe," the price of which is 40 cents per burner. This burner is made by the American Lava Co., of Chattanooga, Tenn.

"The truth, the whole truth and nothing but the truth" —— J.N. Willys

PRODUCTION must be gauged as to its value, depending upon the methods employed. In experimental plants, for illustration, the output is limited to a single model; it is whittled out by a slow and laborious process; it represents, when completed, a more or less imperfect crystallization of the half-baked ideas of the inventor, who hopes by thus proceeding to make one more progressive step in the direction of perfection, realizing all the while that his own ideas are incoherent and his plans incomplete, and the workmen who undertake the task under such conditions, having no facilities but their bare hands and the class of machine tools that are used in general machining work, will be quite content if the automobile will run at all.

* * *

AFTER the completion of the first model of a car, despite the fact that the soul of the inventor is spread thinly over its working parts, it takes but a few moments for the man who pays the bill to arrive at the sane conclusion that he has put up a lot of money and received in return an ill-contrived mess that is rendered the more conspicuous by the noise it makes when it does run—granting that it will run at all. There are too many automobilists who are able to testify, as a matter of personal knowledge, to the facts as herein set forth. They are able to say that when the man who pays the bill finds himself the possessor of an aggregation of noise and confusion, he promptly transfers the obligation to one of P. T. Barnum's old and respected friends—Barnum having proved that "there is a sucker born every minute."

* * *

FIRST models, under the circumstances, must not be regarded as efficacious for exacting work. The next step in the evolution of an automobile comes as a revision of the first model; were it listed as an eatable it would be called "hash." Those who have patiently supported the automobile industry from the start, and who purchased their experience with real money, will appreciate just what this means, and they will understand that safety lies in the selection of perfected automobiles.

AFTER progressing thus far, the builder of cars on this plan is confronted by the unpleasant knowledge that he cannot build anything unless he first provides the requisite facilities. The chances are that his lack of experience will not permit him to intelligently select the facilities, and his first attempt in this direction will parallel his first effort as represented in the building of the model car.

* * *

PERHAPS the unfortunate would-be builder of automobiles, when he reaches this point, strikes a balance and locates a shortage that makes heavy inroads into a half-million dollars. In recounting his experiences, as he mourns his loss, he is not likely to forget that his customers are sharing his misfortunes; he loses real money, and they acquire junk at a cost.

* * *

THERE is nothing to suggest real production in the plan as above outlined. No part of such an effort is likely to lead to the goal of standardization, and, unfortunately, the builder suffers quite as severely as the purchaser of the ill-contrived product; they are both the victims of ignorance goaded on by enthusiasm, with no limit from the maker's point of view until he reaches the end of his credit; and as for the purchaser, he buys experience.

* * *

SUCCESSFUL manufacturers are those who have passed beyond this experimental stage—those who have dealt honestly

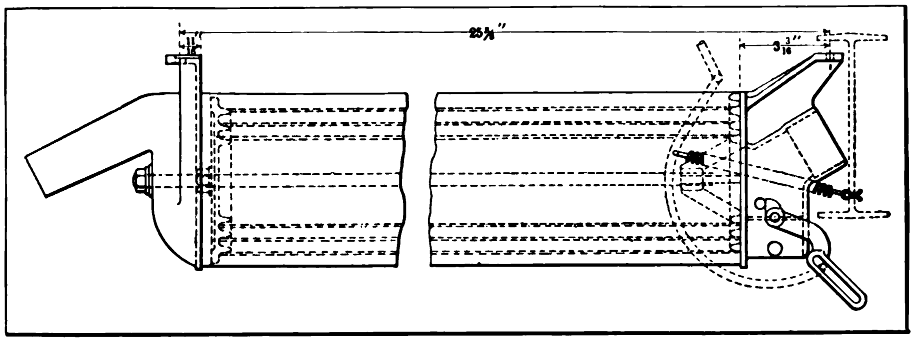
E—Example of Milling Work Using an Angle Plate Fixture and an Inserted Tooth Compound Milling Cutter Boring and Facing the Hand-hole in a Planetary Gear Housing in One Operation with themselves, hence honestly with their customers, and have made the fight along constructive lines, finally arriving at the only conclusion that can be reached in the long run, i.e., good automobiles emanate from the laboratory as a basis for action, and are definitely designed under the direction of a chief engineer aided by an efficient corps of assistants.

* * *

BUT engineers do not build automobiles; they merely design them. When it comes to the production in fact, there are special tools and facilities, as plans, patterns, templets, gauges, and instruments of precision, with buildings in which to place them, and an organization that is capable of directing their use, all to be provided and at a cost that would stagger the purchaser were the output limited to a single car. Even an output of 1,000 cars per annum offers but slight encouragement.



Section of the silent muffler showing symmetrical design and method of fastening same to the chassis frame

JUST to show that absolutely first-class automobiles cannot be designed and constructed excepting in large quantities, the following approximation of some of the items of fixed cost is offered·

Cost of drawings for a single model	$6,000
Cost of patterns for a single model	24,000
Cost of jigs and fixtures for a single model	50,000
Cost of special machine tools for the work	50,000
Laboratory expenses incurred in investigating	8,000
Miscellaneous expenses, as fitting out in the foundry, dies for drop-forging work, and the hundred and one other small items that must be included	20,000
Total	$158,000

These are good average results that cannot be bettered in a plant that is noted for absolutely interchangeable work.

WHAT do these figures portray? Remember, there is no automobile represented in $158,000 worth of cost; there are no buildings in which to house the machinery; there are no officers and men to direct the work; there is nothing, in fact, but the list of special things that must be had before the most skilled men in the world will be able to build a car that will come up to standard.

* * *

DOES it not mean that the fixed charges which must be added to the cost of every car made will be on a basis as follows:

For an output of 1 automobile	$158,000.00
For an output of 100 automobiles	1,580.00
For an output of 1,000 automobiles	158.00
For an output of 10,000 automobiles	15.80

* * *

IS it not plain, with no chance of mistake from any quarter whatsoever, that the enormous cost for special tools and facilities will be just as high if one car is built as it will be if 10,000 automobiles are made? Is there any way by which a $50,000-a-year advertising man, with his splendid array of glittering generalities, can get away from the fact that the fixed charges for each automobile made can only be reduced if the total number of cars is increased?

* * *

IS there any sense in listening to the explanations of the builder who says he can do accurate and interchangeable work without these costly facilities? Is

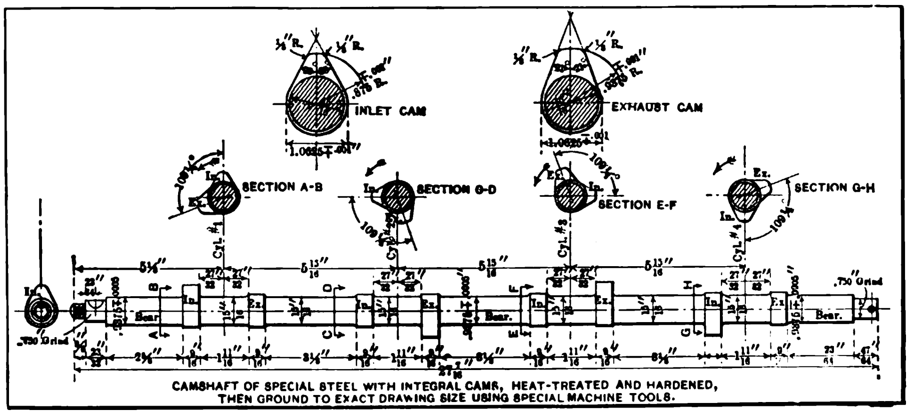
he not trying to substitute cheap cleverness for necessary cost? Is it not true that it is cheaper for him to pay $50,000 a year for a man to write his advertising copy than it is to pay $158,000 for special tools, by means of which he could build a car so good that he would not be afraid to make a show-down?

* * *

WOULD a business man be able to keep outside of a lunatic asylum were he to expend $158,000 for special tools for which he would have no use? Would his confreres in business permit him to make this enormous expenditure were they not convinced of the necessity for so doing? Could the entire engineering world be wrong about this matter? Don't forget that they all, without exception, advocate the necessary first cost to bring about standardization, the duplication of parts, and the suppression of the personal equation in the shop.



Plan of camshaft with integral cams, well-proportioned contours, and exactness of finish

NATURE breeds variety. No two blades of grass are alike; no two men were ever known to be exact duplicates of each other. Criminals are identified with absolute certainty by the Bertillon system; this is but another way of saying that the imprints made by the cuticle at the tips of the fingers of no two individuals are identical. And when the gamut is run the conclusion must be reached that standardization of product in a shop is utterly impossible unless the personal equation is done away with, and the men who perform the operations are so guided by jigs and fixtures that they cannot introduce their own ideas, even should they be inclined to do so.

* * *

IN a word, it costs $158,000 per model to guide the workmen in the path of standardization—that is to say, to prevent them from introducing the variations that would surely come were they permitted to exercise their own judgment. In the earlier efforts along automobile lines, every maker was compelled to rely upon the skill of his men. There were no machine tools available such as would satisfy a more exacting situation; it was impossible to find a market for all the automobiles that would have to be made in order to limit the fixed charges to a reasonable sum, doing the work with jigs and fixtures as guides, thus excluding the vagaries of the workman.

* * *

REMEMBERING that the recommendations of the great engineering societies of the world are absolutely in favor of standardization at whatever cost, not forgetting that all the good automobiles that can now be had from any source whatever are built in shops that are fitted out with this costly equipment, what faith can be put in the statements of the assemblers of aggregations of materials that go into cars, when they say that there is no occasion for incurring so large a cost and going to so much trouble?

* * *

PERHAPS these assemblers have more faith in their ability to advertise money out of a purchaser's pocket than they have money with which to buy the necessary facilities to build a good au-

tomobile. On second thought this must be true, because with proper facilities it is possible to determine with great accuracy the cost of building automobiles so that the investment becomes scientific in its certainty of an honest return, and there is no gainsaying the fact that these assemblers of aggregations of picked-up material have the good taste and the sense of proportion that would compel them to prefer a certainty rather than to indulge in a speculation. What they need is the ability and the funds.

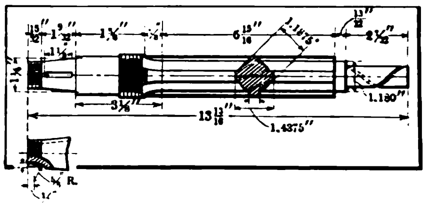
If good automobiles can be built without first acquiring a sufficient measure of the facilities used under first-class conditions, why is it that some racing cars as they are used for advertising purposes, are so designed and constructed that they differ from the stock car specifications, and have to be entered in free-for-all events on that account? Why should the builders of this character of automobiles spend thousands of dollars in racing, and thousands more in making special cars for racing, if it be true that they can build good automobiles under bad conditions?

* * *

Is it not a reasonable assumption that the amount of money expended in thus hoodwinking the public, is far less than the $158,000 per model, for every model turned out, that would have to be paid for the special tools alone in order to manufacture a standardized automobile? Is there any chance of being mistaken when it is said that the public is hoodwinked every time a specially built racing car is scheduled in an event, if in the advertising of the result it is alleged that it is a stock car proposition? Is there any reason for concealing the fact that the A. A. A. rules are sufficiently liberal to permit of making alterations to cars if they are entered?



Presenting sliding gear spindle

* * *

There is ofttimes expressed the belief that good automobiles will ultimately be sold at a very low price. A few years ago, when the hand-whittled products of Europe were cast adrift on the shores of America, and men of means with sporting proclivities purchased them at prices that ranged all the way from ten thousand to twenty thousand dollars apiece, they were looked upon as the toys of the rich, but American engineers and toolmakers recognized the weakness of the foreign situation.

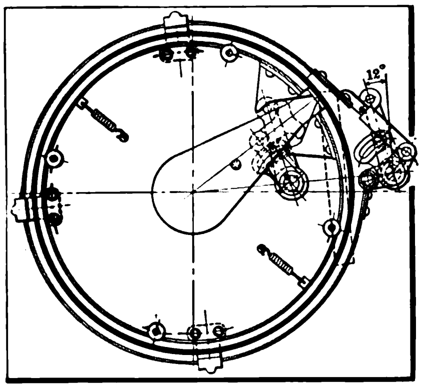
any substance to speak of behind the reckless claims that are made in advertising generally? Would the men who pay for space in which to make their unsubstantiated claims pursue such a course if the purchaser were to write the word "Contract" across the top of the page and ask the maker to put his signature at the bottom of it?

* * *

WHEN a man goes out to buy an automobile and he notices all the claims that are being made for this or that make of car in the advertising thereof, why is it that he permits a salesman to slur over the definite claims therein made and substitute a lot of colloquial piffle that releases the maker from further responsibility and puts the burden of proof up to the purchaser?

* * *

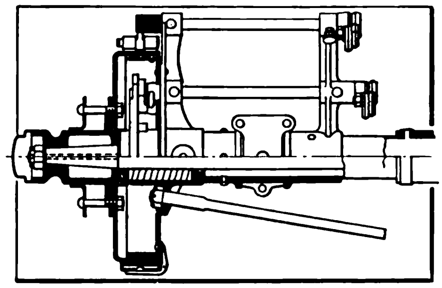
IS it not strange that even good business men forget, as the saying goes, "Ignorance of the law excuses no man?" In business law *caveat emptor* represents a principle that is as fixed as the rock of Gibraltar. It is another way of saying: "Let the purchaser beware." There is no chance of the buyer of an automobile getting the little end of the horn if he will sally forth with a string tied to one of the fingers of his right hand to remind him of *caveat emptor*, and another string tied around a finger of his left hand to remind him of his status as a buyer, i.e., "Ignorance of the law excuses no man."



Section through brakedrum showing method of adjusting take-up

* * *

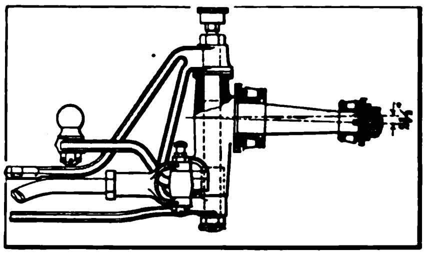
THERE still remains a considerable problem to be solved by the man who prefers to receive a dollar's worth of automobile for each dollar that he expends. This problem is shared by the maker who elects to deliver a dollar's worth of automobile for each dollar received. It is self-evident that an automobile that will deliver perfect satisfaction to one man may be entirely unsatisfactory to another—both cars may be thoroughly good in every way for the work for which they are intended.



Section of live rear axle showing hub pressed on taper end

THE wise purchaser first examines himself with a view to determining his needs; he then proceeds to examine the automobiles of the makes that promise most. It is a matching process, just as a sample of cloth is used and matched up if more cloth of the same kind is wanted. When the purchaser finds the automobile that matches with his needs, he may then proceed to buy it. He will be wise, if, after having made up his mind, he keeps it made up. Substitutions "a la drugstore" are distinctly bad.

FROM the maker's point of view, since there is a diversity of purchasers to satisfy, he is compelled to invest in a promising variety of models in order that he can honestly entertain the various types of intending purchasers. Experience teaches that purchasers may be divided into from ten to fifteen distinct classes, each of which requires models of cars that are sufficiently at variance with each other to demand that they be given separate consideration; and if one model of car requires the expenditure of $158,000 for special tools in the building of it, even though this figure is not multiplied by the number of models turned out, does it not indicate that the maker who is lacking in means finds himself incapable of manufacturing a sufficient number of models to satisfy the existing demand?



Part section of front knuckle and shank of I-section front axle

* * *

WHAT is the alternative? Obviously, the maker with limited facilities must either cater to a restricted clientele or fudge up the required number of models, doing the best he can with his restricted facilities. Will this effort on his part, however ambitious, be up to the standard set by engineers as necessary to the well-being of the automobile business? How can it be? No other established business, ever succeeded in spreading out thin and at the same time maintained a reputation for that peculiar quality which brings a glow of satisfaction to the cheek of the fastidious.

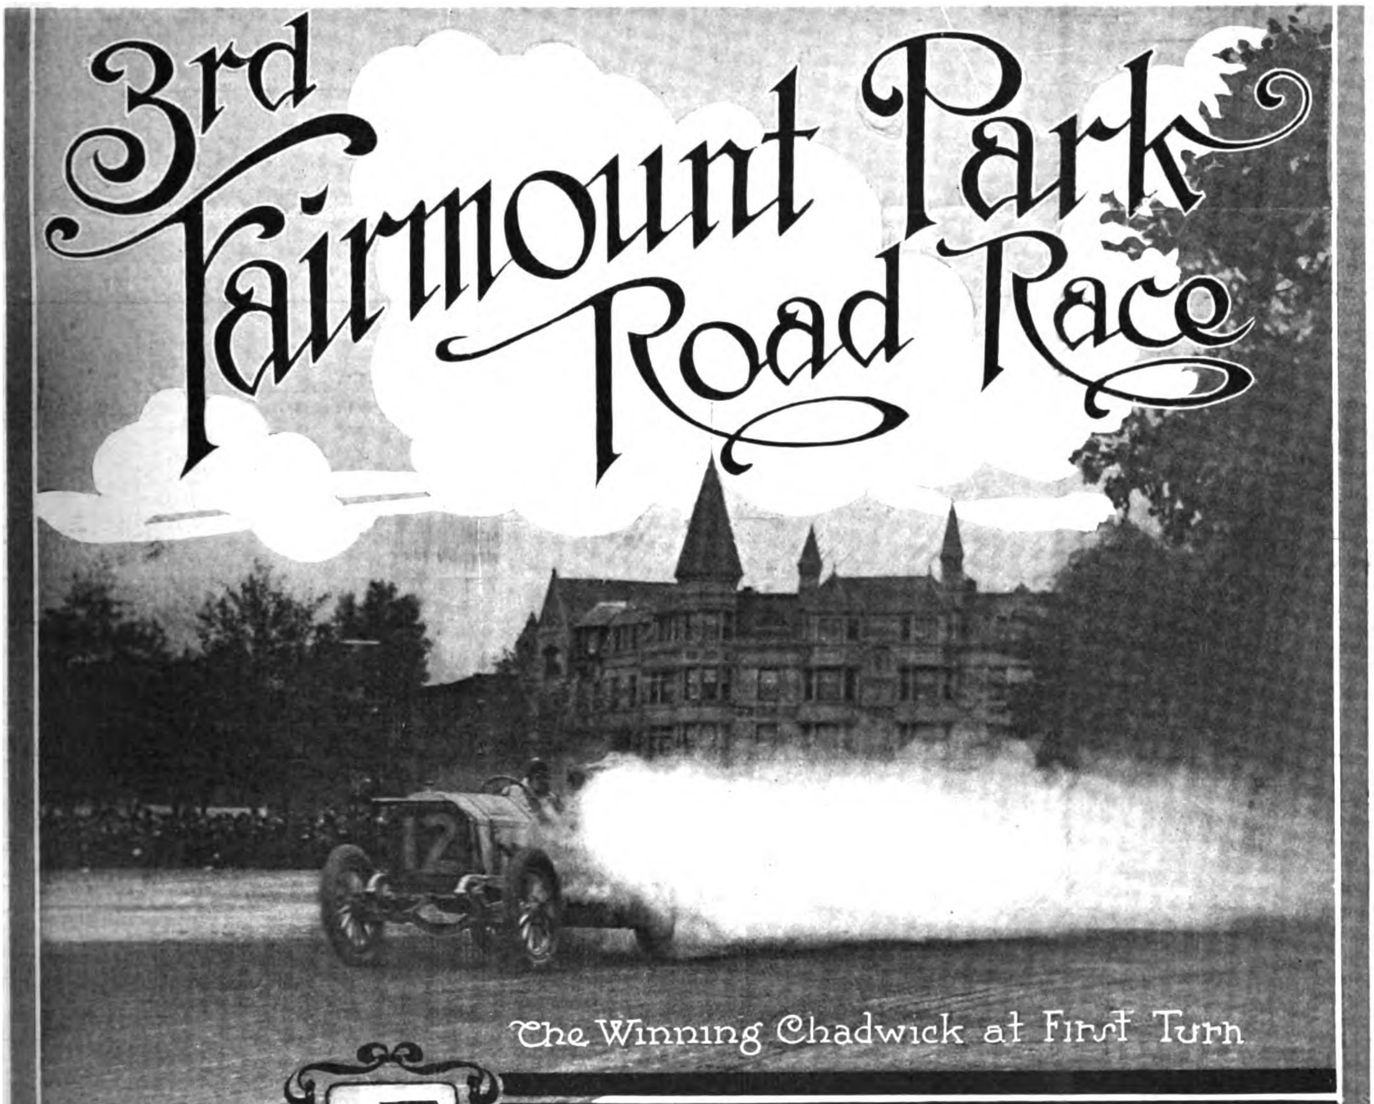
VOL. XXIII NEW YORK—THURSDAY, OCTOBER 13, 1910—CHICAGO No. 15

THE AUTOMOBILE

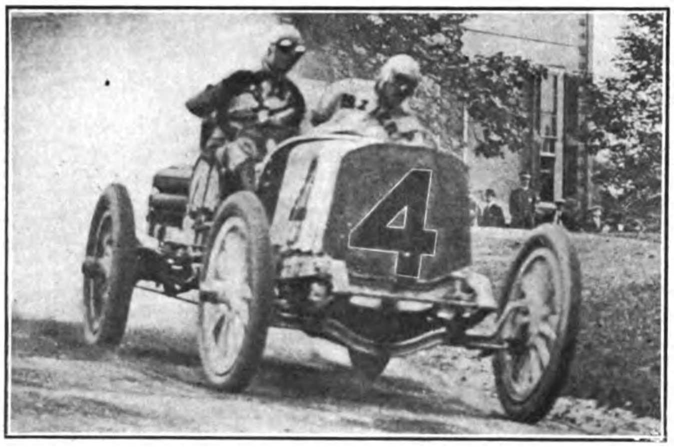
3rd Fairmount Park Road Race



The Winning Chadwick at First Turn

FINISHING in a neck-and-neck drive, the intensity of which has seldom been equaled in a sporting event of any kind, and never in an automobile road race, the Chadwick entry, No. 12, driven by Len Zengle, won the third renewal of the Fairmount Park Road Race at Philadelphia, Saturday, from the speedy and consistent Lozier, with Ralph Mulford at the wheel. For ten laps of the course, the winner lay close to the Lozier, sometimes one flashing by the grandstand in front and sometimes the other.

The finish was hair-raising. In the next to the last lap, the Lozier had established a lead of 9 seconds and shot past on the final round with the same steadiness that had characterized its running all through the race. There was a difference in the starting time of 80 seconds in favor of the Lozier and this, with the 9 seconds it led in actual time, put it 89 seconds ahead of the Chadwick at the start of the last lap. When the Chadwick came whistling down to the stand, the signal from the pits informed Zengle to "beat it" and the big car reared like a living thing as it set sail for the white flyer. Less than a minute after it had disappeared from view around the first turn a telephonic message conveyed the news that the Chadwick was suffering from tire trouble. It was learned that the car had thrown two shoes passing the turn. By a marvelously quick change the tires were replaced and the car was once more on its way.



Lozier, No. 4, rounding Sweet Briar Hill turn

It seemed ages before the white hood of the Lozier appeared at the head of the stretch, tire trouble having been experienced, but when it did it came with a rush that seemed able to carry it to victory. In fact, after the report of the tire trouble suffered by the rival car, the appearance of the Lozier, even after a slow round, 9:53:70, seemed to warrant its reception as the winner.

Soon into the straightaway swung the long red-hooded car. The pilot knew it was a matter of seconds and he drove as never before. So fast came the giant that the eager crowds drew away involuntarily as the car shot past. Only a few realized that there was a winning chance, but everybody understood that Zengle was making a most terrific and spectacular effort. The magpie banner waved as he sped on and the electric device showed that he had beaten the total elapsed time of the Lozier by about 6 seconds.

It was a Philadelphia victory gamely won, for the car is made not far from the Quaker city and the driver is a native son. The winner is entitled to every credit, but the showing of the Lozier was quite as good, when it is remembered that the winner had the advantage of 161 cubic inches piston displacement. Stoddard-Dayton, No. 29, driven by De Hymel was third, about 8 minutes later, and National, No. 3, Aitken, the same car that finished third in the Vanderbilt cup race, was fourth, five minutes behind the Stoddard. Five others finished the full course as follows: Mercedes, Jackson, Westcott, Pullman and Apperson.

Eight out of the nine cars that finished were stock models of American make, emphasizing the lesson taught in the running of the Vanderbilt Cup. The foreign racing machines experienced bad luck or something else, for they failed to stand up.

The race was a beautiful contest. It was managed and administered with skill and fairness. It was witnessed by fully half a million persons and not a single spectator was even frightened, so perfect were the policing arrangements. Neither were there any sanguinary accidents to the contestants, although several of the cars met with mishaps and two mechan-

Pullman, No. 10, at Sweet Briar Mansion

icians suffered broken arms. The course is comparatively slow on account of the numerous hazards along the winding eight-mile route.

Besides winning the grand prize of $2,500, the Chadwick also wins its class prize in Division 6C, amounting to $1,000 and a silver trophy presented by the city of Philadelphia. In addition there were the usual number of accessory prizes.

The race was really five races in one for there was a cash prize hung up for each division under Class C from 2C to 6C. The prizes were $1,000 each and a silver trophy given by the city.

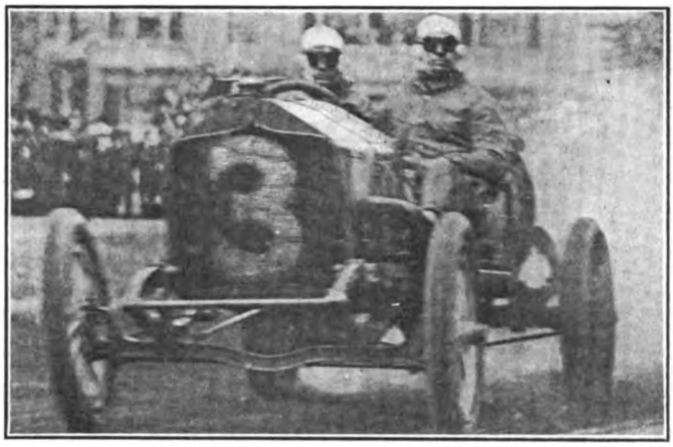
The Chadwick was the only contestant in its class to finish the course, all the others meeting mishaps.

The Lozier won in its class, Division 5C, but three others finished in that division.

National, No. 3, Aitken, won the division 4C honors, but two others completed the full route.

Pullman, No. 10, driven by Gellard was first in Division 3C.

The Abbott-Detroit, No. 21, driven by Padula was the winner in Division 2C, but did not have to make the full distance as the car was the only one running in that division when the race was declared finished.



National. No. 3, passes the Smith Memorial

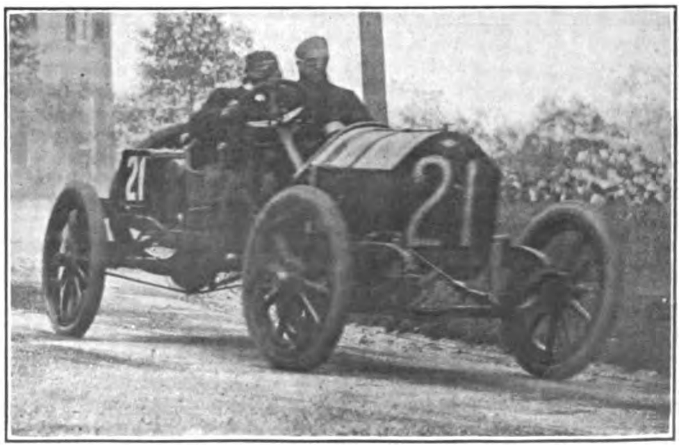
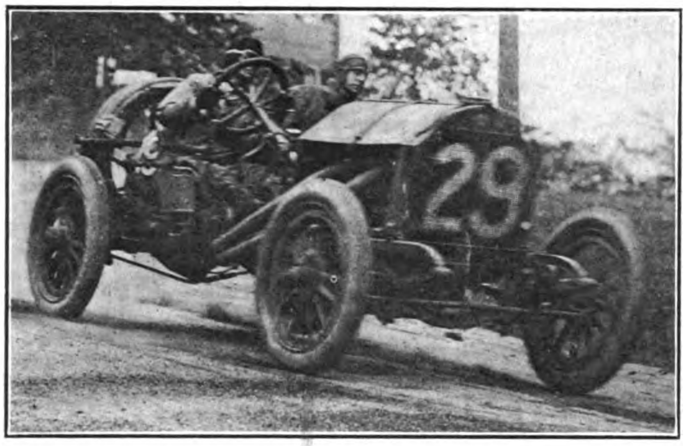
The story of the race by laps is rather complicated because of the fact that there were so many factors to be considered.

Starter Gantert made as perfect a job of getting the thirty-two cars away from the starting line as has ever been seen on a race course. The Apperson, No. 1, was first away and the Otto last, 5:10 after Hanshue's mount. Each car was given ten seconds headway. The fairness, exactness and perfection of the start was generally commented upon. Chadwick 25, led in elapsed time at the end of the round, in the fast time of 8:10. The Lozier was first to make the trip, leading past the stand, but its time was 8:32. Chadwick, 12, was third, a shade faster than the Marmon, 28, but both were credited with 8:43. National, 16, led in its class and Ford, 24, showed the way for the small cars.

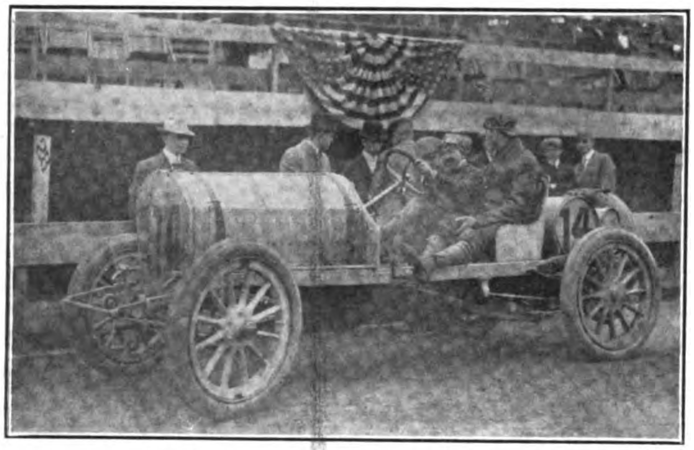
The Lozier assumed the lead in the second round with Stod-



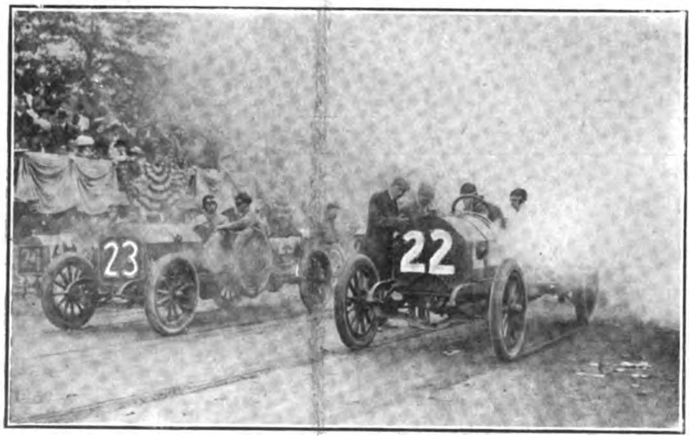
Abbott-Detroit car, No. 21, on Sweet Briar Hill



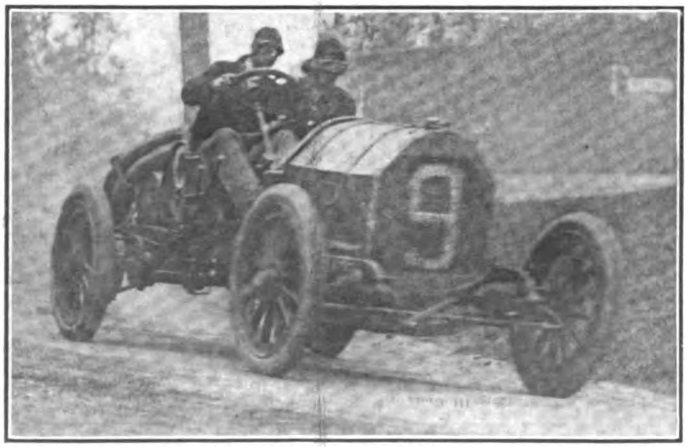
Stoddard-Dayton, No. 29, at Sweet Briar



Jackson car, with Cobe at the wheel



Simplex, 22—Beardsley; Westcott, 23—Knight



Apperson, No. 9, rounding into the Concourse

dard-Dayton, 29, Benz, 5, and Chadwick, 12, tied for the place positions.

In the third round, Chadwick, 25, regained the lead and held it for three laps, closely pressed by the Benz, 5, and the Lozier. In the sixth round Chadwick, 25, driven by Mitchell, was eliminated by plunging off the course and striking an embankment.

Benz, 5, driven by E. R. Bergdoll, went to the front in the sixth round and from there to the end of the fifteenth lap it set a fast pace, running about a mile a minute. At the end of that round it was leading the Lozier by 52 seconds; with the Chadwick, 12, in third place. National, 3, was fourth in point of speed and led its class by a wide margin. The Marmon that had run second in the Vanderbilt Cup had met with a mishap in the thirteenth round and the Pullman 10, had established a winning lead in Division 3C. Abbott-Detroit, 2, led Cole, 18, in their class. Marmon, 11, broke the lap record in the twelfth round with 7:38.

In the next round, the Benz broke an oil feed and was withdrawn, leaving the Lozier out in front with a comfortable lead over the Chadwick, 12. From this point to the finish it was a duel between these two such as has been rarely witnessed. For four laps the Chadwick gradually reduced the margin of about two minutes, and in the twentieth round it finished with an advantage of three seconds. It stayed in front through the next lap, but in the following round the Lozier got into the van once more, with three seconds to spare. The Chadwick seemed to have something in reserve, for whenever it reached the lead, the driver was signaled to take it easy. Nevertheless he was forced to make some exceedingly fast rounds at this stage through the beautiful steady speed of the Lozier. Lap 22 found the Lozier in front, but in the next round the Chadwick was ahead by one second. Lozier made the twenty-fourth lap in less than eight minutes and led its rival by nine seconds at the tape.

At the beginning of the last lap there were still thirteen cars left in the race, and word was given that enough cars would be given a free course to finish as would be necessary to decide upon a winner in each class. As has been said, the Chadwick won the grand prize and its class in record-breaking time, but the race was not called off until Abbott-Detroit, 21, had finished 22 laps and was running perfectly, without any opposition.

The National, winner in Division 4C, ran steadily and well throughout. The Westcott, 23, completed the full course in this division as did also the Jackson, 14.

Pullman, 10, was the only car to finish in Division 3C, but Mercer, 15, and Otto, 32, were both running perfectly at the end.

The Abbott-Detroit, winner of the 2C prize and trophy, had a stormy passage. Both Cole entries succumbed to mechanical troubles before the end and the Ford was disqualified for using four men to replace a wheel in lap 20. Abbott-Detroit, 6, had dropped out early with ignition troubles and Abbott-Detroit, 2, had shed a wheel while far in the lead in lap 20. This left Abbott-Detroit, 21, a certain winner, and when the victors in the larger class had been determined, Padula was given the checkered flag while still three laps from home.

The race was conducted as usual by the Quaker City Motor Club. Harry C. Harbach, secretary, was responsible for the preliminary arrangements, all of which worked out to a mathematical nicety. The timing, scoring, starting, judging and everything connected with the race was well done in an orderly manner. The police arrangements would command admiration anywhere. The technical committee, under the supervision of A. L. McMurtry, was quick and decisive in its actions. In order to show how carefully the committee did its work, it may be cited that the winning Pullman car was given the white flag in one of the later rounds by Mr. McMurtry, when it was noted that a tire carrier was dragging from the rear springs. At the time the car was struggling for the lead in its class and this peremptory action might have caused it to lose. But the committee figured that it is better to be safe than sorry, and the Pullman had to stop and adjust the dislodged part and won anyway. R. E. Ross was referee. Something like $11,000 was realized for charity by the sale of grandstand seats and concessions.

1910 Edison Storage Battery

FIRST INSTALLMENT—WALTER E. HOLLAND DELIVERED A PAPER BEFORE THE TWENTY-SIXTH ANNUAL MEETING OF THE ASSOCIATION OF EDISON ILLUMINATING COMPANIES HELD AT FRONTENAC, THOUSAND ISLANDS, N. Y., SEPTEMBER 6, 7 AND 8, 1910, OF WHICH THIS IS AN ABSTRACT

ANNUALLY the Association of Edison Illuminating Companies meet for the purpose of reviewing the past and outlining the future for the good of the service. Among the problems that have to be coped with is the "peak load" as it relates to the long hours during the day when the machinery that is necessary to cope with the "peak load" lies in idleness, or at least operating far below rated capacity. Any demand of sufficient moment to serve as a loading factor that can be so regulated that it will come during the long hours of the day, excepting at the time of peak loading, presents unusually attractive possibilities, and it is on this account that the central stations throughout the land look to the electric vehicle with a favorable eye.

In the presentation of this paper, Walter E. Holland, of the Edison Storage Battery Company, owing to his great familiarity with subjects akin to the central station problem, mindful of the possibilities of the new Edison storage battery, and appreciating the professional keenness of his audience, presented relating matter in concise and technical form, some of which will scarcely be of immediate interest to automobilists in general, but an attempt will be made here to differentiate sufficiently to permit readers of THE AUTOMOBILE to arrive at some of the reasons why the time taken to develop the Edison storage battery to its present state of perfection was not unduly long, especially if it will be remembered that M. Gaston Planté started out to commercialize lead-lead batteries in 1861, and a coterie of eminent physicists worked upon the problem from that day to this, notable among whom mention will be made of Emil Fure, who brought out his modification of the lead-lead battery in 1879, not forgetting that Brush patented the paste, paint, or cément idea in 1881; and it is this modification of the lead-lead battery that ultimately became prominent in electric vehicle work, it being the case that the original Planté type of battery would scarcely deliver more than three to four watts per pound, and it was a great stride in the direction of commercial acceptability when Charles F. Brush introduced modifications that made it possible to realize as much as eight watts per pound of elements on a sufficiently stable basis to render the electric vehicle a factor, despite the wonderful possibilities that reside in the internal combustion motor as it is at present used in gasoline automobile work.

Thomas A. Edison, with his customary penetration, tersely points out that the first thing to do in the final solution of the electric vehicle problem, assuming that the battery is available, is to establish a charging plug outside of the door, in an accessible position, of every electric central station in America. As Mr. Edison said, "The charging facilities must come first; the automobilist will decline to put his money into a vehicle that cannot be charged with certainty at a sufficiently large number of points along the road to serve his purpose." Mr. Edison also said: "Central station managers everywhere have the capacity for charging vehicle batteries as a by-product, and the cost to them of building a 'lean-to' to serve as a protecting shed for automobiles when they come to be charged, together with the cost of installing charging plugs, is so slight, and the advantage is so obviously great, that it is a mere matter of telling them about it to get them to fall into line."

One of the great advantages of annual meetings of the managers of central stations lies in the concerted action that can be taken when the propitious time arrives, and Mr. Edison made the point that it is now only a matter of a few brief months when charging facilities will be afforded by the small central stations in the little hamlets betwixt great centers, as well as at the larger stations that now cater to the automobilist and find him a profitable customer because he comes for his "charge" and takes away a by-product.

Among the many other interesting points that were brought out at a recent interview, the rather naive way that Mr. Edison took advantage of in offering a broad justification for the future of the electric vehicle may appeal to the automobilist, who, while perfectly satisfied with himself and the position he occupies, may not be averse to having his intellect tickled by the inference that there must be something in it since gasoline costs $32 per ton, and steaming coal, such as is used by central station companies, is at a premium price when the cost is one-eighth of the price of gasoline.

The central station man has in his possession two fundamental reasons why he can afford to make concessions to the automobilist who wants a charge for his battery. The first reason is that he has his machinery lying in idleness (90 per cent. of it) 22 hours out of every 24. The second ground for his interest presents itself when the fact is taken into account that what the central station man really sells is the energy that he abstracts from coal, putting it in the form of electricity, the cost of which to him is represented by the cost of the coal per ton, plus the money he puts into it in making the conversion from the energy as it resides in coal to the electric energy that he pours into the battery when the automobilist comes for his charge. It would be a far stretch of the imagination were the incidental costs which must be added to the initial cost of the coal to expand sufficiently to make heavy inroads into the ton price of gasoline. The margin is insurmountably wide and the central station man

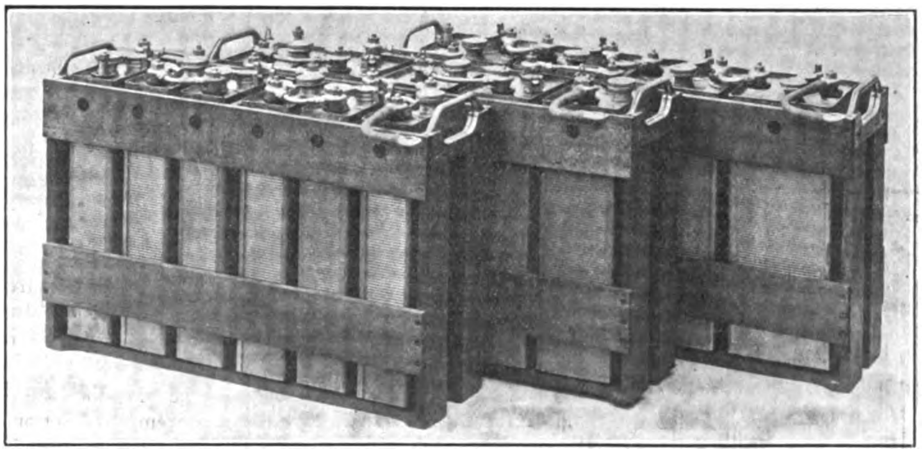


Fig. 1—The Edison vehicle battery, showing how six cells of battery are joined and assembled in crates

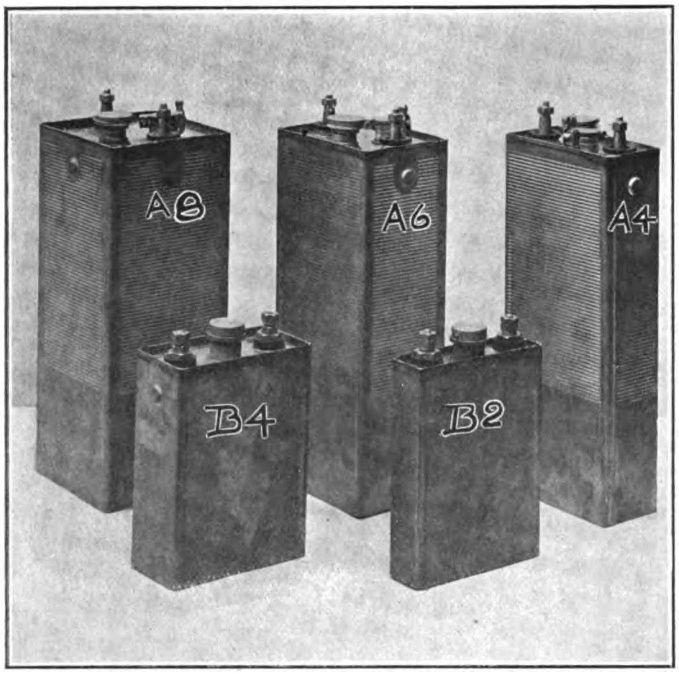

Fig 2—Showing the five sizes of cells, as used in general service, transportation, lighting and ignition work

is in a position to compete with gasoline, and as Mr. Edison concluded, when he said, "it puts the whole burden on the battery—with a good battery that will not wear out, there is nothing left but to bask in the sunlight of prosperity."

Many Obstructions Put in the Way of the Battery

Keeping in mind the difference between batteries as used in central station work and the battery problem as it is slowly being worked out for transportation purposes, it is more to the point to clearly state the impeding influences and indicate how they are being coped with than it will be to simply assume that a battery with a satisfactory output per pound of material used will serve for vehicle purposes, disregarding the thousand and one other things that stand in the way of success. There is more significance to be attached to Mr. Edison's process of elimination than rightfully belongs to the fact that Mr. Edison as an inventor of repute has patented and is commercializing a type of storage battery.

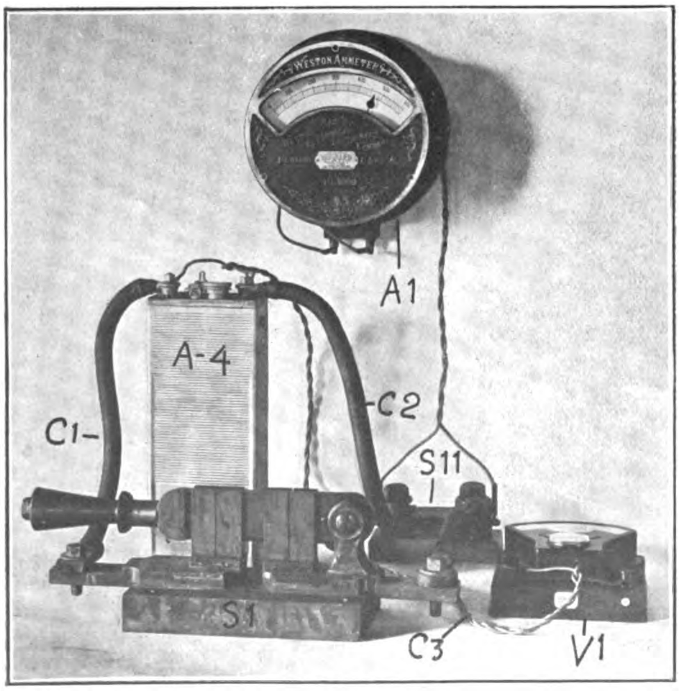

Fig. 4—Apparatus used in short-circuiting test

The history of the patent offices in the various civilized countries is largely composed of that character of historical material that clearly describes all the generic types and modifications of storage batteries that have failed to do satisfactory vehicle work. "The proof of the pudding lies in the eating of it." There are two parts of this pudding that would induce acute indigestion for the eater. The most conspicuous part of the moment is in the guise of the relatively large number of gasoline automobiles in proportion to the relatively small number of electric vehicles to be had. The second consideration takes into account the enormous amount of money that has been wasted in storage battery work and the relatively poor results obtained therefrom.

When Mr. Edison states that the future of the electric vehicle is clearly incumbent upon the battery he reiterates a situation that history proves, not forgetting, however, that there are so many good things to be said in favor of electric vehicles that despite storage battery imperfections they have survived and are looked upon by the average autoist as entirely satisfactory under certain conditions, approximately competitive under other conditions, leaving it for the storage battery in its final perfected form to extend their radius of travel and place at the disposal of those who desire to tour, using electric vehicles that will take them where they want to go, means of obtaining a charge at the end of each day's run wherever they happen to be.

A very significant statement made by Mr. Edison may be restated as follows: "When the storage battery reaches a state of perfection where it will furnish all the energy required to propel a car for a whole day there remains nothing to be desired." Obviously, a tourist who wants to keep on the go day and night will find a Pullman car much more to his liking. Moreover, there is no profit to be derived from the supplying of automobiles to men who want more than can be a reasonable expectation from even a railway locomotive. In railway work the locomotives are treated with precisely the same consideration as a horse—when they do their allotted work per day they are groomed, stalled and permitted to rest. Unless the men who use electric vehicles can be brought to understand the reasons why even locomotives are treated with the consideration that is accorded a horse, it is not profitable to do business with them.

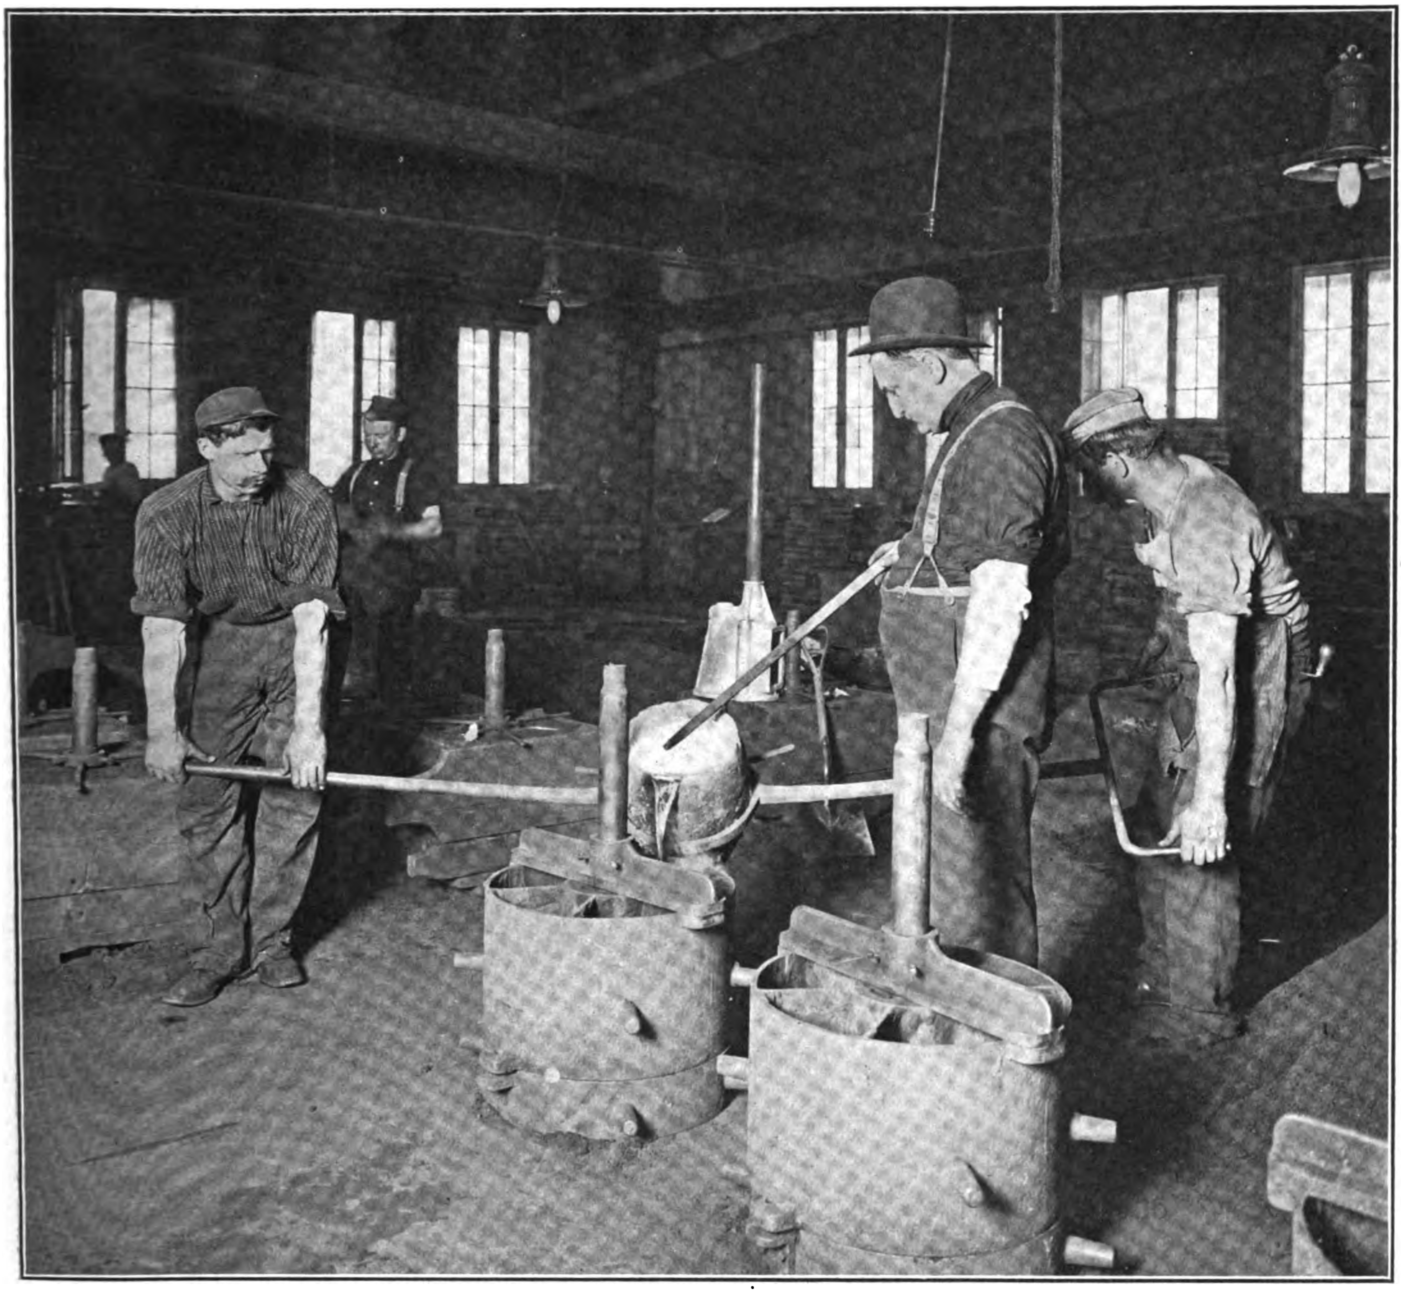
Narrowing the discussion down to the specific differences between the conditions of service that storage batteries render in central station work as compared with that of transportation, it must first be pointed out that in central-station battery service the batteries are installed under the most precise conditions in well-lighted and properly ventilated rooms, and experts attend them day and night, year in and year out, giving them a precise charge at the right moment, as indicated scientifically with instruments of precision designed for the purpose and performing all the other duties as based upon electrochemical considerations that experience has proven to be efficacious in the prolonging of life, limiting the delivery of current to that which is good for the battery from the life point of view, rather than to compel the battery to serve under severe conditions.

Turning the attention to transportation service for the moment, it is simple to point out that the installation is made in a vehicle that has to negotiate all sorts and conditions of roads under speed variations that are only under the control of men who entirely disregard everything but the point, *i.e.* they wish to go somewhere, or they are on their way back. The battery is subjected to vibration, shock and jar, and the expert who watches the central station battery hour after hour and utilizes instruments of precision for determining everything about it is far away. The great primal consideraton is entirely lost sight of; instead of the battery being limited in its output to that which is good for it from the life point of view, as in central station work, it is required to furnish all the current that is necessary under operative road conditions, entirely disregarding its rated capacity, or the state of its charge.

(*Continued on page 644*)

Among the Makers

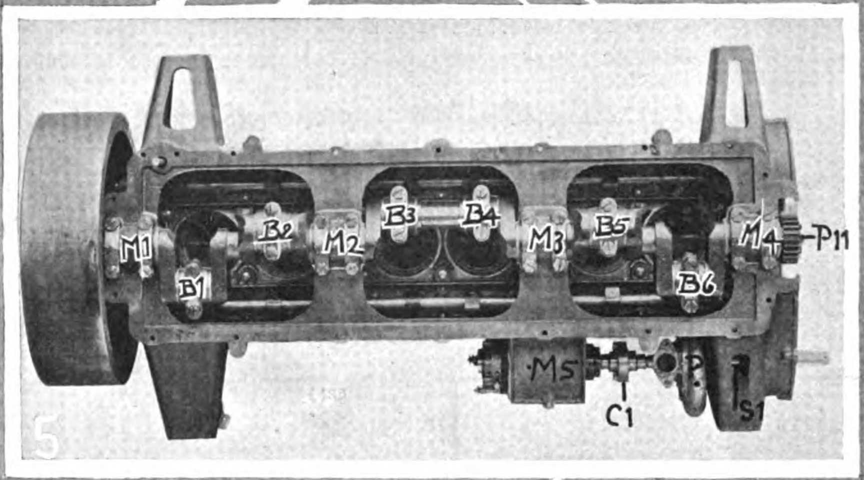
THE PREMIER LINE FOR 1911 BEARS EVIDENCE OF MANY REFINEMENTS—THE ACME S. G. V. FOR NEXT YEAR A DISTINCT INNOVATION—THE ROADER CAR A NEWCOMER



IN THE FOUNDRY DEPARTMENT OF THE RAMBLER SHOP AT KENOSHA, WIS.

MARKET conditions are now quite cleared up; the bankers who were so much concerned a few weeks ago are quite calm, and from what can be seen by those who make a practice of looking below the surface the automobile situation is on a firmer basis than ever. For the benefit of those who may not have followed the situation closely it may not be out of place to point out that the makers are preparing in a serious way for the struggle that competition is bringing, but it is fortunate for the purchasing public that quality, instead of suffering, is bound to be improved, the reason for this lying in the preparing for better work.

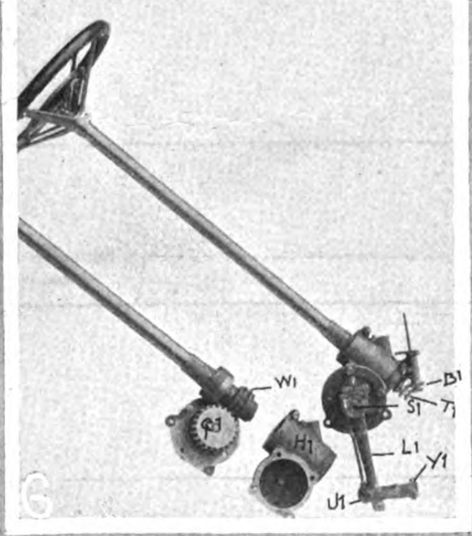
One of the most troublesome branches of the automobile business from the makers' point of view lies in the foundry problem. The procuring of good castings has caused many a maker to go abroad for them, and it has been found that the outside foundry is better able to cope with the "grate bar" problem than it is to turn out good cylinders. That which is true of cylinder castings is equally to be remembered when reference is had to aluminum castings, and the 1911 method of disposing of the troublesome feature attending is to own and operate a foundry in connection with the making of the automobiles.

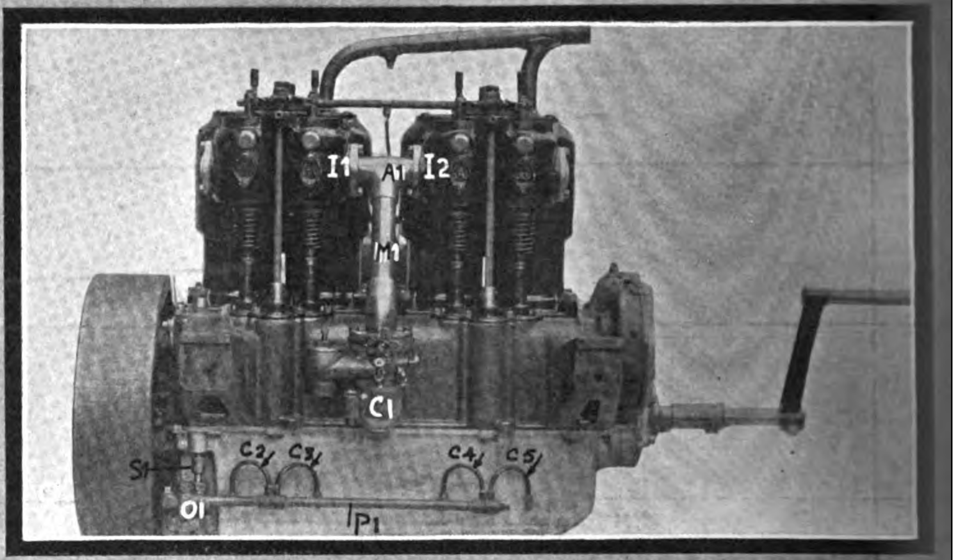


1911 Premiers

TAKING advantage of experience, utilizing the broad foundation which resulted in the Premier car as it is now generally understood, the 1911 models are offered by the Premier Motor Manufacturing Company, Indianapolis, Ind., subject to the refinements of a year, retaining the general plan, and the mechanisms that have proven to be the most substantial. As the table on another page shows, the 4-40 model affords five options, beginning with the "Touring Clubman," including the Limousine and Roadster, while the 6-60 model is in four options beginning with a "Clubman," including Roadster, Touring and Limousine models. The general appearance of the finished cars may be gleaned from a study of Fig. 1, which is a front view of the 6-60 Touring car; Fig. 2, which is the 4-40 Touring car, three-quarter view, and Fig. 3, which is a side view of the 6-60 Touring car, and it will be observed that all three models of this car are of the latest and most approved fore-door designs, with overhanging cowl and a dashing effect generally.

From a mechanical point of view, the several models have a certain similarity; it has been found that a principle that works well in one model is good for the





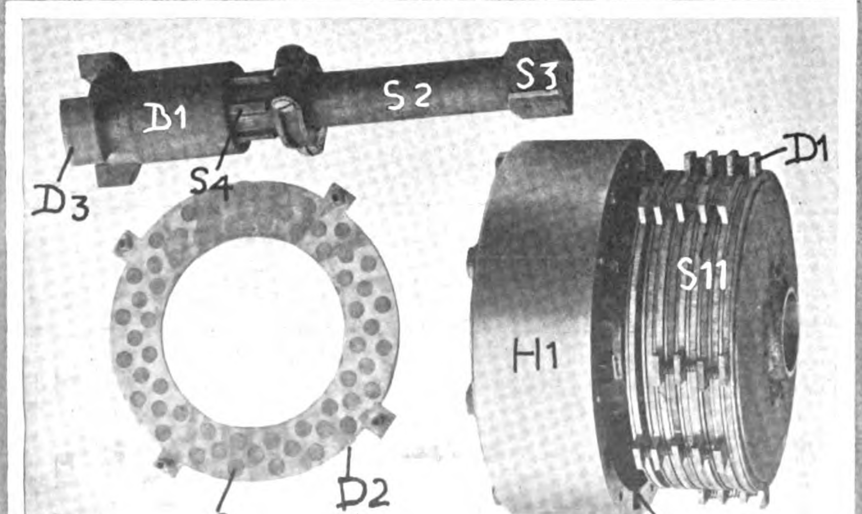


Fig. 5—Six-Sixty motor turned upside down, with lower half removed

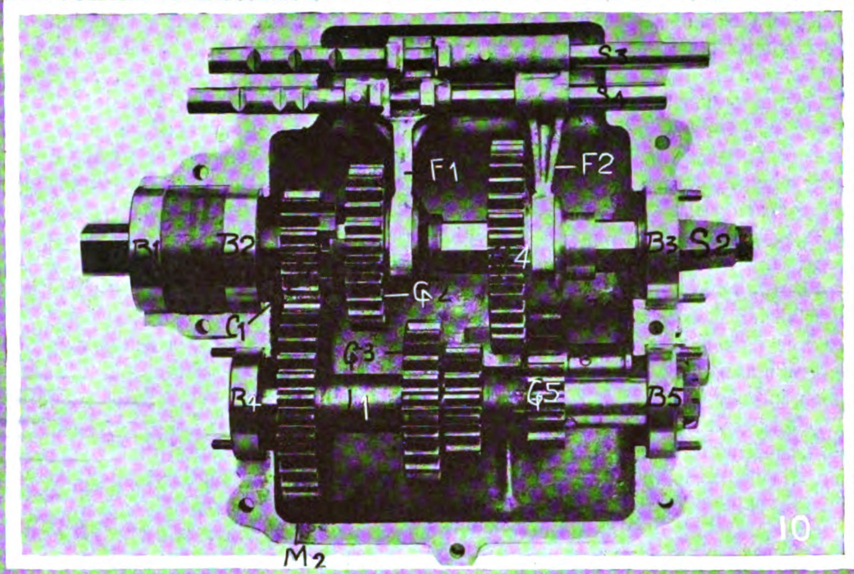
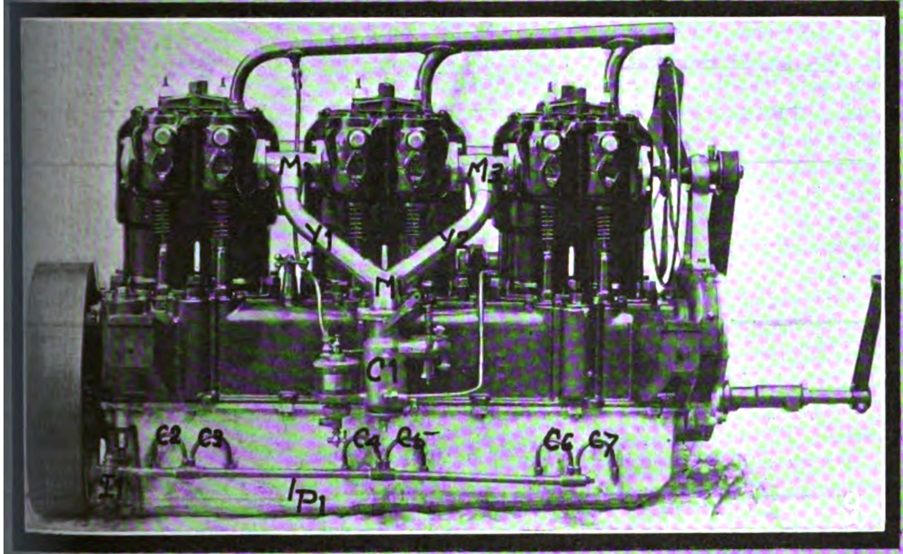
Fig. 8—Right side of Four-Forty motor

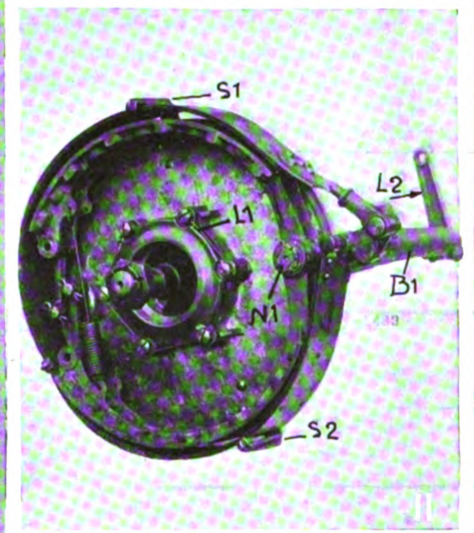
INCLUDING 4-40 FOUR-CYLINDER AND 6-60 SIX-CYLINDER MODELS

other, and Fig. 4 is offered as an illustration of the general plan mechanically, this being of the 4-40 model showing the motor M1, flywheel F1, multiple disc clutch C1, clutch control shaft S1, clutch pedal P1, service brake pedal P2, transmission gear G1, control shaft S2, steering gear G2, transmission side lever L1, and an emergency brake lever L2. Attention is called to the width of flanging F2 of the chassis frame, at the point of narrowing, also to the depth of the frame and the use of pressed steel footboard irons I1. It will be to the point to observe how the lateral L3 is fastened to the side member at the point L4, utilizing a secondary stiffener from the lateral L3 forward to afford a substantial platform for the machinery equipment.

With the general arrangement and scheme of design fixed in the mind's eye, it will be in order to take up with the mechanical detail in which the 4-40 has two pairs of cylinders with a bore of 4 1-2 inches and a stroke of 5 1-4 inches. The 6-60 is provided with three pairs of these cylinders. The only difference then between the 4-40 and the 6-60, from the cylinder point of view, lies in the use of six cylinders instead







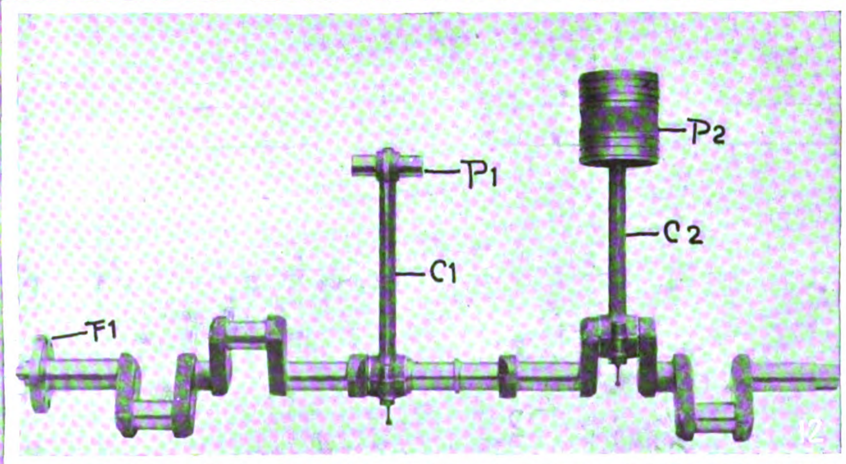


Fig. 9—Looking at the right-hand side of the Six-Sixty motor

Fig. 10—Looking into the three-speed and reverse selective transmission gear

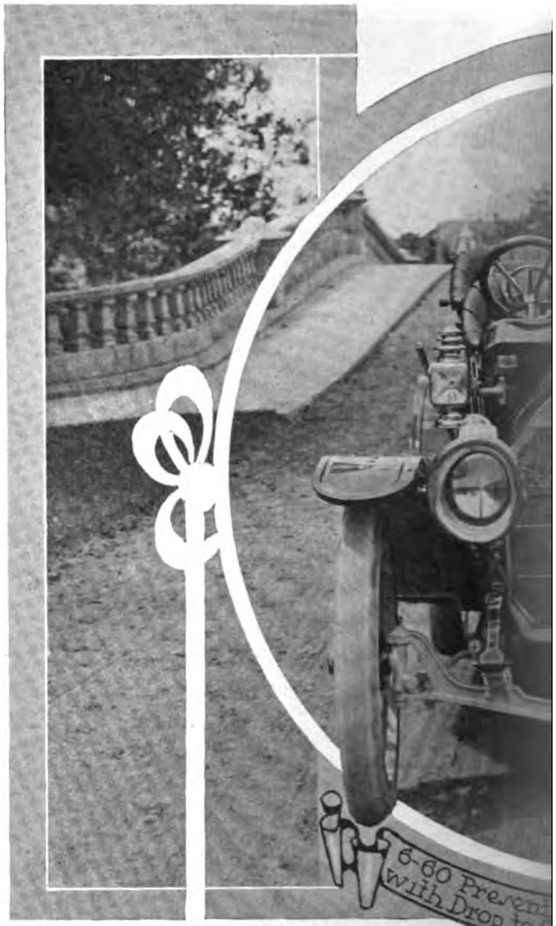
Fig. 11—Details of the brakedrum and brakeshoes on live rear axle

Fig. 12—Crankshaft of the Six-Sixty motor

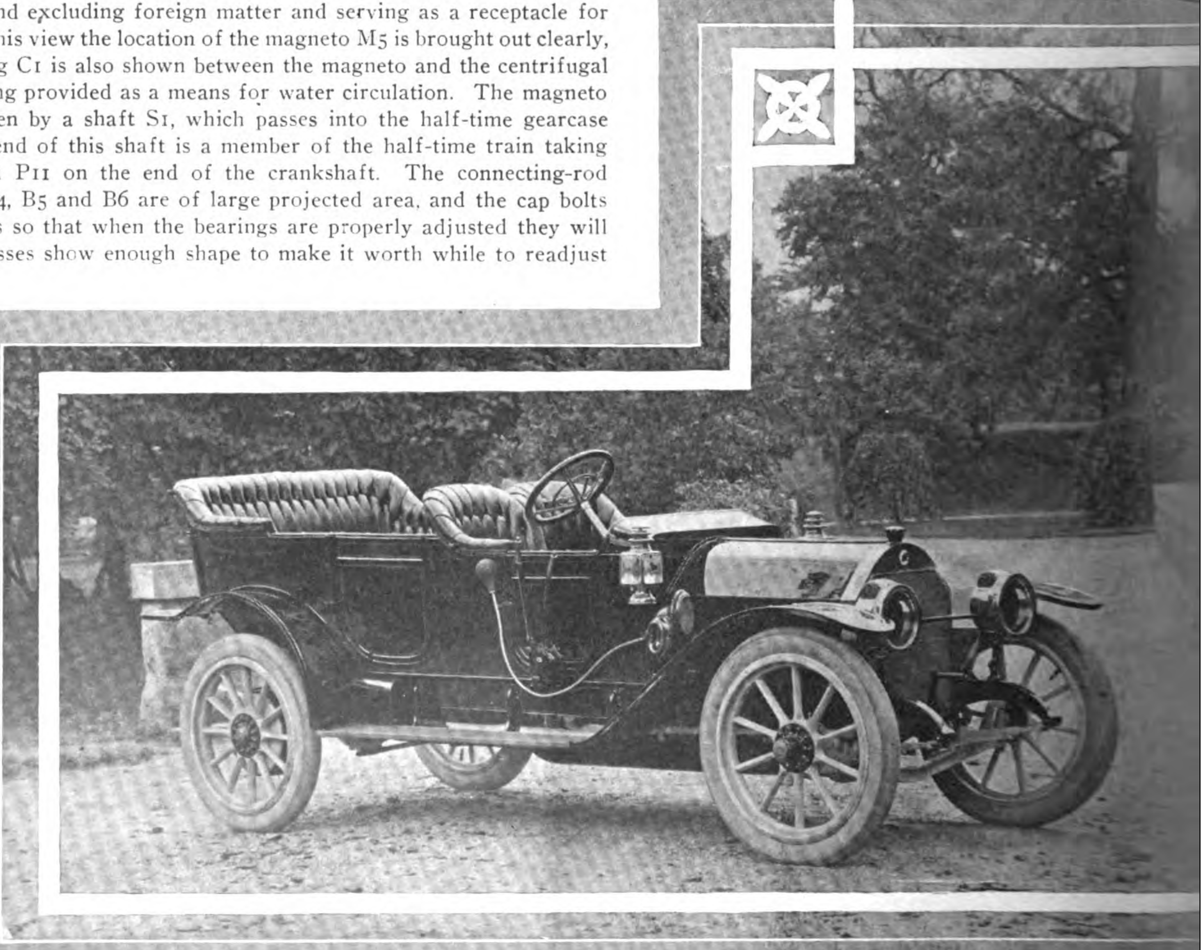
of four. The general appearance of the 4-40 motor is shown in Fig. 8, looking at it from the right-hand side, with a Wheeler & Schebler carbureter C1 located in the mid position, and the manifold M1 leading straight up to an accommodation piece A1, placed between the two pairs of cylinders, flanging to the sides of the intakes I1 and I2, thus making the intake non-tortuous, and particularly adapted for the good work expected of it. The oil pump O1 also shows on this side of the motor with the surplus of oil carried in the lower half of the crankcase, below the level of the pipe P1, and the connections C2, C3, C4 and C5 transfer the oil from the pipe P1 to the respective oilways within, whence the oil is distributed to all the bearing surfaces. This system of lubrication is known as "the return circulating system," and the pump O1, which is driven by means of a gear on the camshaft, with a vertical shaft and a sleeve connection at S1, is of the centrifugal type, while the oil supply in the lower half of the crankcase is equal to about three gallons, and it has been found in practice that the miles per filling of the lubricant is between 500 and 750. There is a sight-feed glass on the dash, which serves as a tell-tale, and the lubricating oil is poured into the lower half of the crankcase through a large opening in one of the crankcase arms.

Referring now to the 6-60 motor as shown in Fig. 9, the similarity of general design will be rendered at once apparent. The carbureter C1 is located in the mid position and the manifold M1 has a branch Y1 to the left, and a similar branch Y2 to the right, leading to a makeup M2 between the back two pairs of cylinders, and a similar makeup M3 leading up between the front two pairs of cylinders. Mixture is distributed to the respective cylinders through transfer ports within the twin castings, and this scheme of distribution of mixture has been found to eliminate the troubles that are generally threatening in connection with six-cylinder work. In the lower half of the crankcase just in front of the flywheel the oil pump I1 is located precisely as in the 4-40 motor, and the supply pipe P1 occupies a similar location with the distribution of oil to the respective feed points through the connections C2, C3, C4, C5, C6 and C7, the only difference being that there are two additional connections. The oil pump is driven by a vertical shaft to a gear from the camshaft; the oil is spilled into the lower half of the crankcase through a commodious opening in one leg.

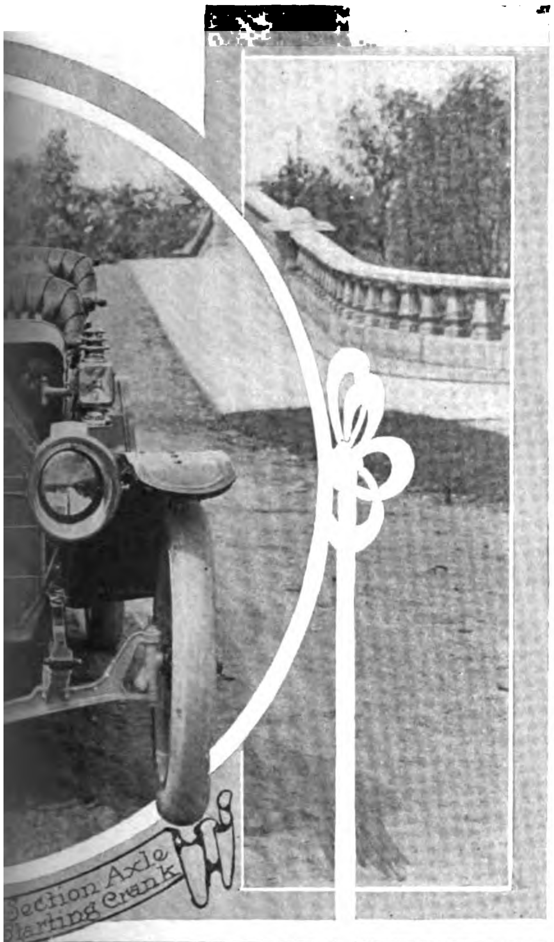
Referring to Fig. 5 of the 6-60 motor, it is turned upside down with the lower half of the crankcase removed, showing the main bearings M1, M2, M3 and M4 with caps carrying the crankshaft on the upper half, thus freeing the lower half of any responsibility beyond excluding foreign matter and serving as a receptacle for the lubricating oil. In this view the location of the magneto M5 is brought out clearly, and the flexible coupling C1 is also shown between the magneto and the centrifugal pump P1, the latter being provided as a means for water circulation. The magneto and the pump are driven by a shaft S1, which passes into the half-time gearcase and the pinion on the end of this shaft is a member of the half-time train taking power from the pinion P11 on the end of the crankshaft. The connecting-rod bearings B1, B2, B3, B4, B5 and B6 are of large projected area, and the cap bolts are provided with locks so that when the bearings are properly adjusted they will remain so until the brasses show enough shape to make it worth while to readjust



6-60 Presen
with Drop to



4-40 with Fore-Door Type of Body, Wide Tonneau Entrance and Over-hanging Cowl



Section Axle Starting Crank

them, but the adjusting operation may be done with but slight labor. Fig. 12 shows the six-cylinder crankshaft removed from the crankcase, and presents one of the connecting rods C1 with the crosshead pin P1 integral, and another of the connecting rods C2 with a piston P2 attached, presenting to view the oil grooves at the lower extremity of the piston, and the piston rings at the upper extremity. The piston is backed off for a part of the distance in the region of the cross-head pin and attention is called to the fact that the construction is light, but care is exercised to afford the requisite strength to prevent deformation under service conditions. The crankshaft is flanged F1 for the flywheel, and the throws are very wide at right angles to the axis, which, together with the use of a fine grade of crankshaft steel and accurate finishing methods, including grinding, bespeaks continuity of service.

The multiple disc clutch is shown in Fig. 7, in which the housing H1 is provided with inverted splines S1 to accommodate the driving extensions D1 and springs S11 are placed between the respective discs for the purpose of separating them when the clutch is disengaged. One of the clutch discs D2 is shown at the left with cork inserts C1 occupying about 20 per cent. of the total area. The clutch shaft S2 has a square end S3 and integral splines S4 with a spline block B1 and integral dogs D3. There are 21 plates having cork inserts and the housing H1 is oil tight into which oil is placed for purposes of lubrication. Driving is done through the housing H1, so that the clutching members that have peripheral extensions engaging the slots S1 take the initial work, and the mating members transfer the load to the shaft S2 Fig. 7, thence to the transmission gear as shown in Fig. 10.

Referring to Fig. 10 of the transmission, it is of the three-speed and reverse selective type with a direct drive on high through the clutch C1, with master gears M1 and M2 imparting motion from the stub shaft S1 to the lay shaft L1, and when the gear G2 meshes with the gear G3 the drive is through M1 to M2, thence through L1 to G3, transferring to G2, and through the prime shaft S2 to the propeller shaft, live rear axle wheels to the point of contact of the tires with the road. To go into low gear, the sliding gear G4 engages the pinion G5 and the drive is through M1, M2, L1, to G5, transferring to G4, thence to S2 and back through the propeller shaft, etc. Sliding of the gears is accomplished by the selectors S3 and S4, using forks F1 and F2. Annular type ball-bearings B1, B2, B3, B4 and B5 support the spindles, which are relatively short and stubby so that deformation is obviated. The gears are cut from nickel-steel drop forgings. The reverse idler I1 is on a separate shaft.

The brakes as shown in Fig. 11 have a total effective surface of 526 square inches, the action taking place upon drums which are integral parts of the wheel hubs, not separable and bolted on. The internal expanding brakes, operated by the foot pedal, are of bronze with 44 cork inserts which act as a cushion when the brakes are first applied. The metal is so distributed around the cork as to radiate the heat generated. The external contracting brakes are fiber-lined steel bands acting upon drums and operated by a hand lever.

Attention is called to the excellence of design of the details and to the locking

*"Touring Clubman." † or 6 or 7. ‡ or 3.

wires L1 with castellated nuts N1 and limit stops S1 and S2, also the long bearing B1 and the drop-forged lever L2.

The steering gear is shown in Fig. 6, it being of the worm-and-sector type with a hardened worm W1 engaging the worm gear G1, enclosed in the housing H1 with a square end shaft S1, and a split hub drop-forged lever L1 with a universal joint U1 in combination with a yoke Y1 connecting with the drag rod. The workmanship throughout is on a high plane and lost motion is absent. The spark and lever control are cared for by means of a pair of beveled sets B1, connecting with a concentric rod and tube T1 leading to the spark and throttle levers on the top of the steering wheel, of Circassian walnut, mounted on a strong spider.

The power is delivered from the transmission to the rear axle by a cardan shaft of liberal size, equipped with two combination slip and universal joints which are packed in grease, and in use over extended periods have given entire satisfaction and excellent service. According to mechanical laws rotary motion can be transmitted uniformly only by two universal joints. At the ends of the driving or propeller shaft are found features of self-evident value, though they have rarely been used in motor cars. These are tapered squares which fit into tapered square holes in the universal joints, and to cut the latter from a solid block of metal was considered impossible until done by Premier engineers. The tapered square system gives a positive connection and is always sure to be of the proper tightness, and is a material advance over the use of a round tapered shaft with key and keyway. The torsion rod is of the double-tube type with the front end retained in a spring-cushioned ball joint.

The rear axle is internally ribbed and needs no external truss rods. It is especially strong under the spring seats where the largest strain occurs, and ensures absolute alignment of bearings under all conditions. The differential is of the bevel gear type and upon it is mounted the main driving gear, which is adjustable laterally, and into it meshes the pinion which is adjustable longitudinally. Eight anti-friction bearings are used in the assembling. The pinion is forged solid with the shaft, contrary to the practice of keying it, and is mounted between two imported annular bearings instead of having both bearings on the front end and leaving the rear unsupported.

At the ends of the axle housing are the brake supports, rigidly attached and hot-riveted. The live axles have three integral large diameter clutch jaws which engage with three clutch jaws on the hubs of the wheels. A liberal annular bearing is placed almost in the direct load carrying center of each rear wheel.

The front axles are single-drop forgings of the Elliott type,

All magnetos are of the Bosch make.

and it is interesting to note that the Premier Company was the first to use a solid one-piece front axle with the spring seats integral and entirely free from one or more welds.

Semi-elliptic springs are used on the front, each 36 inches long, and three-quarter scroll elliptic are on the rear, with the bottom section 50 inches long and the top 26 inches, thus giving exceptional spring length. The steel used is of the best and is an assurance against breakage, and in addition to being closely held by spring clips the front springs, which are subject to the greatest shock, have drop-forged plates which closely bind the several leaves at the center so that they work in thorough harmony and confine the action to points between the spring pad and the hangers.

A comprehensive line of bodies is provided in both the vestibuled and open types, as five and seven passenger touring cars, four and five passenger Clubmen, two and three passenger roadsters, and five, six and seven passenger limousine cars. With the feeling that the superlative has been reached in mechanical construction the Premier production for the coming year will be marked by most careful attention to the perfection of details. Body lines and general contour have been provided which are thought to be particularly effective and impressive. They will be finished in a rich blue-black with panel lines and light striping. The wheels will be a special Premier gray, except in the case of limousine cars, where the running gear is of the same blue-black finish as the body. Fenders are black baked enamel.

Especially liberal tire equipment is an important feature of all the models, and with 36-inch wheels the "4-40" touring cars, Clubmen and Limousines will have 4 1-2 inch tires all around, and the roadsters will have 4-inch tires all around. The "6-60" cars will have 36 x 4 1-2 inch tires front and 5-inch rear.

The Premier price proposition for 1911 affords a wide range of choice. As compared with last year there is a slight increase in prices, the 1911 6-60 touring car, for instance, being catalogued at $3,650, as against $3,500 for the same model in 1910, and so on. The full list is as follows: Model 4-40—"Touring Clubman," four seats, $3,000; five seats, $3,050, and seven seats, $3,100; Limousine, $4,200; Roadster, $2,800. Model 6-60—"Clubman," $3,500; Roadster, $3,600; Touring, $3,650, and Limousine, $5,000.

Paris' Commercial Census

AUTOMOBILE CLUB OF FRANCE COMPILES STATISTICS SHOWING NUMBER OF MOTOR WAGONS OF VARIOUS KINDS IN FRENCH METROPOLIS

OWING to the fact that no taxation is imposed on purely commercial automobiles, it has been impossible to know exactly how many motors of this type were in use in Paris and the surrounding district. This lack of knowledge has just been remedied by carefully compiled statistics secured by the technical committee of the Automobile Club of France. According to these there are 155 large capacity omnibuses owned by the Paris General Omnibus Co., and 48 omnibuses of small capacity, seating 10 to 20 people, owned by other companies. The General Omnibus Co. is under a contract with the City of Paris to increase its motor buses to 800 within a period of three years; this change is being made gradually.

There are 1,095 trucks and motor delivery vehicles in daily service in Paris or its suburbs. These can be classed as follows:

Useful load 1760 pounds to 2 tons	234
Useful load 2 tons to 5 tons	179
Useful load 5 tons and above	143
Other commercial vehicles	120
Postal vans, carrying 1700 to 2600 pounds	156
Tractors and locomotives	60
Total, including omnibuses	1095

These figures do not include taxicabs, which are now slightly more numerous than horse-drawn cabs, nor the city fire engines, all of which must be converted to power within a period of four years.

Figures have been obtained of the fuel employed on the 556 vehicles carrying from 1,700 to 5-ton loads. In 416 cases this is either gasoline or benzol. It is impossible to differentiate between these two fuels, owing to the rapidity with which the change is made from one to the other. Kerosene is only used on five trucks; alcohol in one case only. Coke is employed on 131 vehicles and low grade coal gas on three.

The vehicles using kerosene are Darracq-Serpollet steamers, a type of vehicle which is no longer manufactured. The alcohol was a test case. The coke was employed on such steamers as the Purrey, Turgan and Schars, largely used for carrying paper from the mills in the suburbs to the printing offices in the center of the city. The motors using coal gas are built by the Cazes Company.

French Government to License Foreigners

On the recommendation of the Automobile Club of France the French Minister of Public Works has just announced that his government will take the responsibility of issuing driving and car licenses to persons of other nationality than French. Thus, although America offers no reciprocatory benefits, it is possible for an American automobilist, on landing in France, to obtain an international driving and car license which will allow him to enter eleven countries without formality. This, of course, does not affect customs formalities, which are quite distinct from police regulations on drivers and cars.

During the present season a certain number of American tourists have been touring Europe with international passes obtained in England, but this does not appear to have been altogether in accordance with the convention, according to which it was clearly stated that the holders of the pass must belong to one of the countries having signed the agreement. The passes appear to have been given by the English automobile associations under a misunderstanding. The recent decision of France, which will probably be followed by other governments, removes all possibility of misunderstanding. It also creates the unusual situation of allowing Americans, who are obliged to have a separate license for almost every State at home, to run throughout the length and breadth of Europe without changing their tags. A European crossing the Atlantic receives no such benefit in return.

Acme S. G. V. Model

COMPACT MOTOR ALONG FOREIGN LINES; LIGHT AND TRIM LIVE REAR AXLE; EXTREMELY WELL-DESIGNED DETAILS MARK THE 1911 PRODUCT

DISTINCTLY an innovation as compared with its previous efforts, the Acme Motor Car Co., of Reading, Pa., offers the S. G. V. car in two models, the first of which, Model A, with a touring body, sells for $2,500, and Model B, with a runabout body, at the same price. These models weigh about 2,500 pounds complete, and the motor of the 4-cylinder, water-cooled type has an A. L. A. M. rating of 22.5 horsepower. The fine points in this design are not disclosed in a mere statement of the commercial considerations, but an examination of Figs. 1, 2 and 3 will be sufficient to indicate that the designer was actuated by definite motives, resulting in a power plant that is conspicuous for its clean and crisp adherence to well authenticated engineering methods, some of which are shown in the lines, whereas for the rest it is necessary to unearth the design details and observe that the materials employed, and the methods of adaptation, surpass anything that the Acme Co. has heretofore been able to contrive, despite its experience and the excellence of its facilities.

The motor is of the 4-cylinder, water-cooled type, with a bore of 3 3-4 inches and a stroke of 4 3-8 inches. The cylinders are cast *en bloc* with integral inlet pipes, and referring to Fig. 1, C1 is the carbureter, with a straight intake I1, leading to the inlet orifice O1, which is centrally located between the cylinders C3 and C4. The four cylinders C1, C2, C3 and C4. as a unit, have a common flange F1, bolting to a flanged face on the upper half of the crankcase C6, and the spacing between the cylinders C3 and C4 exceeds that of the cylinders C2 and C3, and C4 and C5. The castings are made with an open head, and in the completed motor a water connection W1 near the front end leads to the radiator. From a point in front of the cylinder C5 a water connection W2 leads to the water pump of the centrifugal type, which is incorporated into the upper half of the crankcase C6 and the water pipe W3 serves as the suction for the water as it comes from the radiator, entering this pipe at the point W4. The motor is suspended between chassis members by the arms A1 and A2, which extend out from each side, and the starting crank S1 is supported by an integral extension of the half-time gear cover G1. The flywheel F1 is of the largest safe diameter and a sufficient width of the flange to afford the maximum flywheel effect with a minimum weight.

Referring to Fig. 3, the magneto M1 is of the Bosch type with a fixed point of firing, thus eliminating a spark advance lever on the steering wheel or other relating mechanisms, and among the attending advantages lies the reduction of the wiring to four leads from the magneto to the spark plugs, they being protected by a copper conduit and quick detachable terminals are used on the spark plugs and magneto; moreover the spark plugs S1, S2, S3 and S4, are of the Bosch type with lava insulation. The exhaust manifold E1 is so designed that the holding bolts B1, B2, B3, and B4, are accessible and the manifold sweeps away as it nears the rear of the motor with a long radius curve at a point C1, so that back pressure is reduced to the absolute minimum.

The lubricating oil is contained in the false bottom of the lower half L1, with oil connections O1 and O2. The oil is circulated by a geared pump driven from the rear end of the camshaft, and is forced through properly contrived tubes to the center and end bearings of the crankshaft; the crankshaft being provided with drilled holes for the passage of the lubricant to the connecting rod bearings, whence it is forced to the wrist pin bearings. The cylinder walls are lubricated by the oil thrown up by the rotating parts. All excesses of oil are carried back to the false bottom in the crankcase, being filtered in transit. A convenient filler is provided in the left rear motor leg.

As a further indication of the smoothness and symmetry of design of this motor, reference may be had to Fig. 2. Looking at the front of the motor, the arms A1 and A2 are of substan-

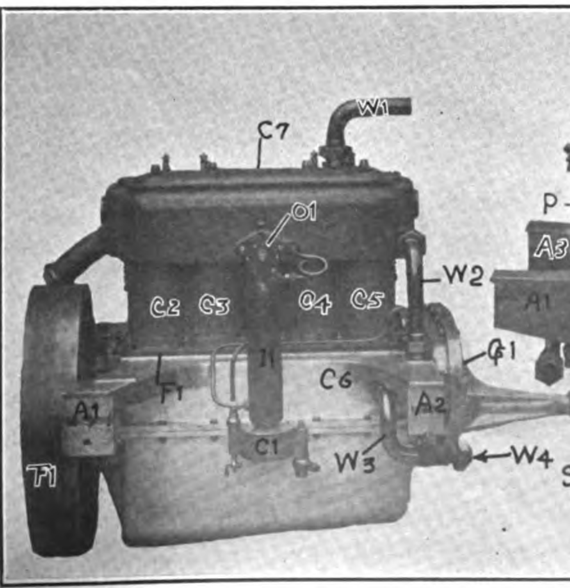

Fig. 1—Carbureter side of the motor

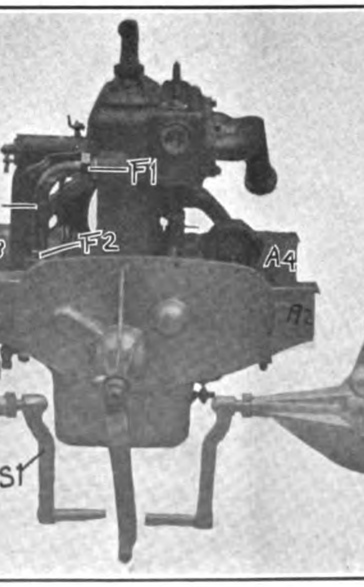

Fig. 2—Front elevation in slight perspective

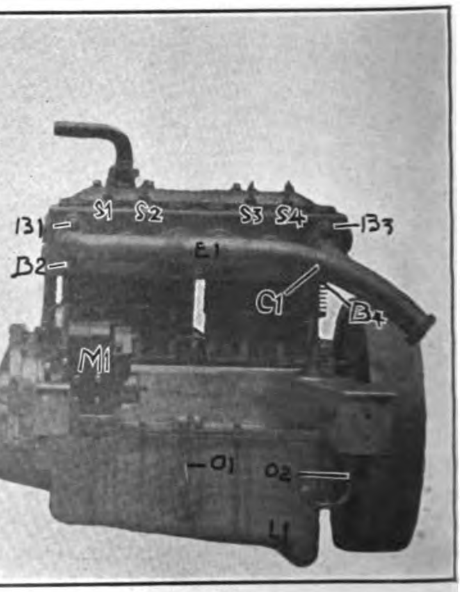

Fig. 3—Magneto side of the motor

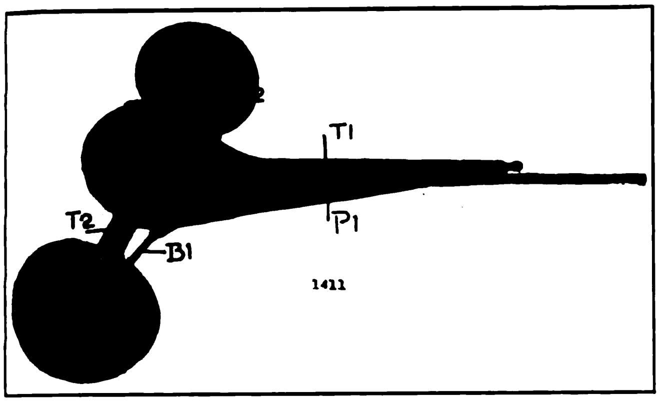

Fig. 5—Live rear axle with bobstays, channel-section torsion tube and rotative perches

tial construction with a considerable depth of web. While the opportunity affords it is pointed out that the arms A3 and A4 are of extra strength, and placed close to the flywheel, so that the gyrations thereof as well as the dead weight are adequately resisted. Coming down to refinements in point of detail, it will be observed that the pipe P1 is provided with accurately machined fittings, F1 and F2, which condition obtains with all the piping around the motor.

In the machining of the motor, in addition to finishing to a definite size and grinding, the domes of the cylinders are machined so that the compression in each cylinder is 76 pounds per square inch absolute, bringing the percentage of compression space to piston displacement of 19.23 per cent., and in fixing upon the proportions of the honeycomb type of radiator as shown in Fig. 4. account is taken of the fact that the flame-swept surface exposed to water circulation is 33.62 square inches per cylinder. In view of the well-defined and accurately governed thermic relations within this motor, the company rating is fixed at 25 horsepower.

With a view to properly governing the kinetic couples, due to speed, the pistons are made relatively light, and ground to a definite size, with a clearance of 0.003 and limits of tolerance of plus or minus 0.00025. The piston rings are cut right and left-handed to prevent lining up. The piston rings are hardened and ground and are secured in piston bosses with two sets of screws which are provided with jam nuts and cotter pins. The connecting rods are made in the I-section, drop-forged, utilizing vanadium steel and are provided with hardened and ground wrist pin bushings. In view of the character of the material employed and the accuracy of finish maintained, the parts composing the reciprocating mass are light in the aggregate, and in this way the kinetic couples, such of them as are unbalanced, are reduced to a point so low that secondary oscillations do not take place within the working limits of speed of the motor.

The crankshaft is cut from a nickel steel billet and is given a successive series of heat treatments. The journals are ground to exact size, barring tolerance limits of plus or minus 0.00025, at a temperature corresponding to the temperature used in the machining of the bearings. The mainshaft bearings are identical with those of the connecting rods; all bearings are supported from the upper half of the crankcase; the lower half acting merely as an oil reservoir. The flywheel is flanged to the crankshaft.

Passing on to the clutch, it is enough to say it is of the multiple-disc type, with 36 steel discs. The leverage is so arranged on the clutch pedal that the pressure necessary to disengage the clutch is 13 pounds. From the clutch to the live rear axle power is transmitted through a propeller shaft as shown in Fig. 5 of the rear axle set, and torsion is taken by the torsion member T1, so that the propeller shaft P1 is free to do its allotted work without having to withstand the pressure of other forces. The axle tube T2 is supported by bobstays B1, and the housing H1 for the bevel drive and differential is of neat design, relatively light, but of great strength. The support for the propeller shaft at the bevel pinion extremity is in the form of a cylindrical housing H2, carrying annular-type ball bearings. The brake shoes S1 and S2 of the internal expanding type are held in the disengaged position by springs S3 and S4, and are expanded by means of a cam C1 with a hinge H3 at a diametrically opposite point.

The service brake drum is mounted on the drive shaft to the rear of the transmission casing. The bands are in halves and are controlled by a right-and-left-hand screw actuated by the pedal. The emergency brakes as shown in Fig. 5 are actuated by a side lever B1, Fig. 6, and the speed changes are manipulated through the side lever S1, Fig. 6. The substantial chassis frame S2 is shown, the shaft of the control coming through the web W1 and the extension shaft of the steering gear passing through the web W2.

The 1911 Roader Car

A CLEAN-BUILT, COMPACT, LOW-PRICED PROPOSITION THAT WILL APPEAL TO THOSE IN SEARCH OF A SERVICEABLE SMALL AUTOMOBILE

SPECIFICATIONS OF THE ROADER CARS

Bore—20-horsepower motor, 3 5-8 inches; 30-horsepower motor, 4 inches.
Stroke—20-horsepower motor, 3 5-8 inches; 30-horsepower motor, 4 1-4 inches.
Wheelbase—104 inches.
Tread—56 inches.
Number of speeds—Two and reverse.
Type of gears—Sliding.
Weight—20 horsepower, 1350 pounds; 30 horsepower, 1500 pounds.
Clutch—Cone, leather.
Cooling—Thermo-syphon.
Lubrication—Splash.
Ignition—Mag. Bosch, H. T.
Springs—Rear, 3-4 elliptic; front, semi-elliptic.
Prices—20-h.p., $650.00; 30-h.p., $750.—F.O.B. factory.

FOR the coming 1911 season a new car of moderate price is being manufactured by the Roader Car Company, of Brockton, Mass. Two models are being placed on the market, the one here illustrated being the 20-horsepower model. The other is built along the same lines except that the motor is larger and gives 30 horsepower. The general lines of the car are very pleasing and with a good rake to the steering post and well-upholstered seats should fulfill the requirements of a comfortable and snappy runabout.

The chassis is of U-section stamped steel to which are attached ample mud guards with side valances to keep out all dust and mud. Both models are fitted with a four-cylinder motor.

The four cylinders are cast *en bloc* and outside the moving parts there are only two castings. The bore of the 20 horsepower is 3 5-8 inches and stroke 3 5-8 inches, and the 30 horsepower has a 4 1-4 inch stroke and the bore is increased to 4 inches. A main feature of the motor is its smooth running, and silence has been attained without loss of power, the flywheel being partly the cause of this, as it is so designed as to allow the car to run on the high gear as low as 4 miles per hour without perceptible jerk. Good hill-climbing qualities are claimed for the car. The combination of flywheel, compression and length of starting crank makes the motor easy to start without unnecessary exertion.

Included in the price of the car is a Bosch high-tension magneto, which is the system of ignition employed on the car, thereby eliminating all battery inconveniences. The splash system of lubrication is used, by which the entire mechanism is kept constantly bathed in oil. The water-cooling is effected by thermo syphon, thus doing away with all pump troubles.

The circulation leads are of ample diameter and the water capacity is extra large. The radiator is a combination of a tubular and cellular type. The gasoline tank is placed at the rear of the bucket seats high enough to give a good head of fuel for the carbureter even on the steepest hill. The gasoline is fed by gravity, and the capacity of the tank is 15 gallons.

The gears are located in the rear axle casing, doing away with an extra casting for the gear box and following a practice that is being adopted by several makers of high-priced automobiles. It also simplifies the car to a certain extent for the novice, giving him less lubrication to look after, and reduces weight quite perceptibly besides eliminating intermediary shafts and joints. The sliding-gear principle is used and provides two forward speeds and reverse. Shaft drive substantially built is the method of transmission.

The suspension has been well thought out and the rear springs are three-quarter elliptical, 1 3-4 inches wide; the front springs are semi-elliptical, insuring an easy-riding car. Two independent brakes are fitted and both operate on the drums at the rear wheels.

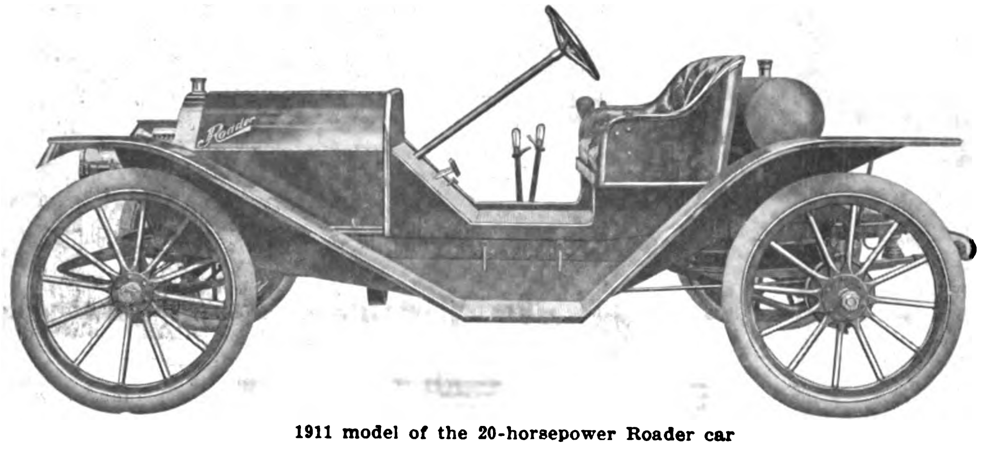
The foot brake is of the external contraction, while the emergency, operated by a lever placed in a convenient position to the driver's hand, is of the internal contraction type. The wheels are 34 inches in diameter and are fitted with 34 x 3-inch tires. The wheelbase is 104 inches and the tread 56 inches. The speed claimed by the makers should satisfy those looking for a fast car; they state that the 20-horsepower model will attain 50 miles per hour and the 30-horsepower a mile a minute.

The standard colors of the Roader car are Roader red or lead gray, and the equipment included in the price consists of two side and tail lights, tools, tire repair outfit and pump. The price of the 20-horsepower model is $650 and of the 30-horsepower, $750, both f.o.b. factory, and when crating is necessary an extra charge of $5 is made.

The firm manufacturing these cars is not new to engine manufacturers, as it has for several years been engaged in the manufacture of motorcycles and engines for same. New machinery of the latest and most up-to-date type has been installed to cope with car building, and although the factory output for 1911 will be limited, no pains are being spared to make everything to standard gauge.

Germany's New Automobile Law

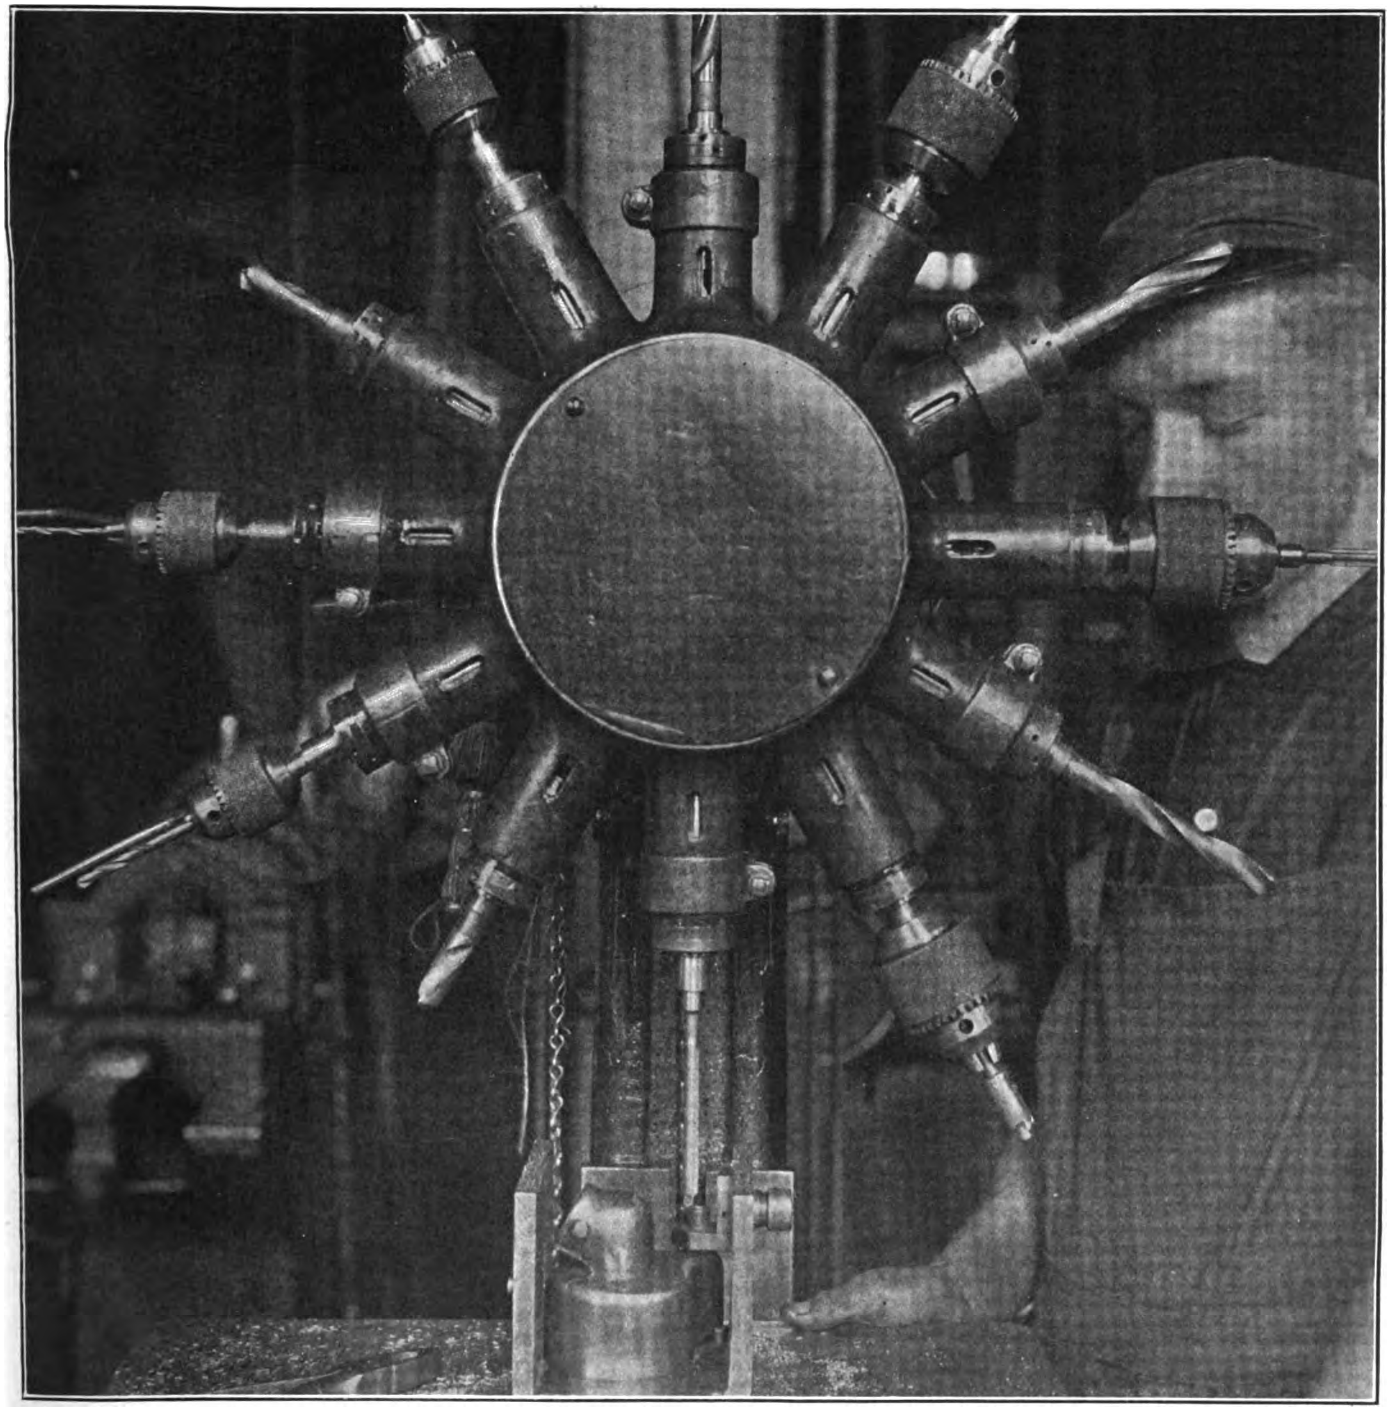
New German regulations for automobile traffic prescribe that only such persons shall have licenses as drivers whose vision is two-thirds perfect without the use of glasses. The new law seems to be enforced in all its strictness mainly against professional drivers, but the physicians entrusted with the examination of the eyesight refuse in many places to make any discrimination in favor of owners, and it is feared that the law, if it remains on the statutes, will eventually affect one-half of the officeholders and other academically educated persons who generally drive their own automobiles without the assistance of chauffeurs. It is suggested that some very beneficial results may in the end be derived from this hardship, since it may lead to renewed investigation of the true causes of myopia in school children, with regard to which much of mystery obtains, and eventually to a material reduction in that mass-murdering or at least crippling of the sense of sight which may be charged against every school system which is otherwise efficient. It is also argued by the advocates of the law that as railroad men have to submit to eye tests, it is but just that those who drive automobiles should similarly qualify themselves



1911 model of the 20-horsepower Roader car

Engineering Section

DEVOTED TO THE DISCUSSION OF ENGINEERING PHASES OF AUTOMOBILING, INCLUDING DESIGNING AND CONSTRUCTION FEATURES OF PRODUCTS, AND INFORMATION TO AUTOISTS



TURRET-HEADED DRILL PRESS WITH GIG FIXTURE USED IN THE ELMORE PLANT

IN the process that is now going on, having for its basis the standardization of the automobile, there is just a little opposition on the part of the purchasing public, due to the fact that the average autoist has an "ideal" in his mind's eye, and, unfortunately, this ideal bears but little relation to good practice as it is based upon experience. It will be found in the long run that experience counts, and if the maker is not conforming to the ideal of the new autoist it is due to the fact that the siren call of experience tells the maker that the things that look so good to the man who has not tried them are not just what they ought to be.

If men who build automobiles for a living find that certain things do not continue the good promise that the first glance would seem to indicate, purchasers will be wise when they bow to the dictates of experience.

Novel Two-Cycle Motor

LESLIE WALKER'S DESIGN OF AN INTERNAL COMBUSTION ENGINE WHICH IS AN ENTIRELY NEW DEPARTURE IN AUTOMOBILE PRACTICE

SINCE the advent of the valveless motor, automobile engines incorporating new ideas have cropped up on all sides. A novel type of construction, particulars of which appeared in the *Automotor Journal,* does away with the usual type of crankshaft and uses what might be termed a wobble block. The designer, C. Leslie Walker, is taking active steps to complete one of the engines in order to test its anticipated merits.

Referring to Fig. 1, it will be observed that in this "wobble-gear" type of engine construction the cylinders A, which may consist of any desired number arranged parallel with the main shaft and equidistant around it, have their pistons B coupled up by ball-ended connecting rods C to a disc D, which is mounted freely upon the main shaft E, but upon a special portion of it that lies at an angle to the axis of the shaft instead of being coaxial with it. A little consideration will show that as the shaft revolves, the disc D will follow the path that is indicated in the diagram, and that if it is prevented from rotating with the shaft it will cause the pistons B to reciprocate to and fro in their cylinders just as though they were arranged in conjunction with an ordinary crankpin. The all-important point, however, to observe is that the ring D must be suitably anchored, and that everything depends upon the exact motion that it is compelled to take by the anchorage mechanism, as to whether or not smooth running will be secured such as can only result from a steady rate of acceleration and deceleration of the pistons, as they start from rest at one end of their cylinders, and as they come to rest at the other end. In many forms of "wobble-gear" engine hitherto proposed, this lack of correct control on the part of the anchorage device has led to abnormal degrees of vibration as well as to resultant excess of strain on the moving parts, rendering the system impracticable.

Diverting one's attention now to Fig. 2, it should first of all be recognized that there are five cylinders, A arranged in the manner described about the hollow main shaft E, and that the wobble ring D is mounted upon that shaft in just the same manner that is indicated in Fig. 1, except that a double row ball-bearing designed to take the end thrust as well the load is introduced between them. Also it will be seen that the shaft E is carried on large ball-bearings suitably formed to withstand the end thrust that is of course inseparable from engines of this type.

One of the most important things to observe in Fig. 2 is the layshaft D_2, which is mounted parallel with the main shaft E and is carried by the stationary portion of the engine which includes the cylinders and the oil-tight casing E_1 around the shaft E and its specially-shaped flywheel E^2 that gives a true rotational balance to the wobble disc D and its moving masses. This layshaft D_1 is driven through gear wheels D_2 from the main shaft, and the speed at which it is caused to rotate is double that of the main shaft. Its central portion (between the two bearings D^3) is eccentric with its axis of rotation, and thus it may be regarded as a kind of crankshaft having a very long crankpin on which is free to slide a large ball D^4 mounted axially with the crankpin, and this ball is in turn provided with a spherical socket in the wobble ring D. It is sufficient for the purposes of this article merely to state the upshot of the anchorage device of which we are now speaking upon the connecting rods C and their pistons B. These connecting rods have ball-and-socket joints, as in our diagram, Fig. 1, and it is through them that the power is transmitted from the five pistons B to the main shaft E during the five consecutive and overlapping firing strokes that succeed one another in regular rotation around the shaft. And it is, of course, also these connecting rods that cause the wobble ring D to make the pistons travel back again to the far ends of their cylinders during the ensuing exhaust and intake stroke. That which is important, however, is that during each revolution of the main shaft E the big end of each connecting rod C is caused twice to describe a small circular path, using the spherical small end as a pivot. The actual degree of angularity of the connecting rod is therefore at all times constant, even though the direction of angularity is continually changing, and is, moreover, very small in itself. Movement of this kind is entirely free from jerkiness, and the corresponding travel of the piston B is similiarly admirably suited for smoothness of running—being that which would result with a connecting rod of infinite length on an ordinary crank engine.

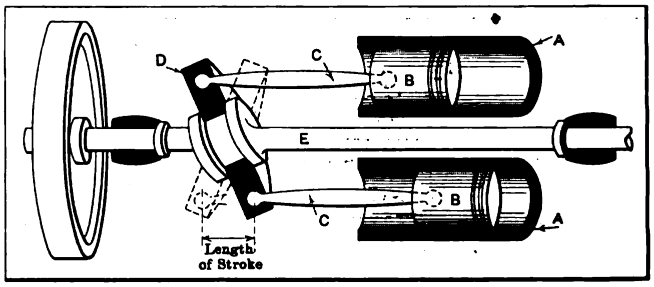


Fig. 1—Diagrammatic sketch indicating the principles of a "wobble-gear" engine

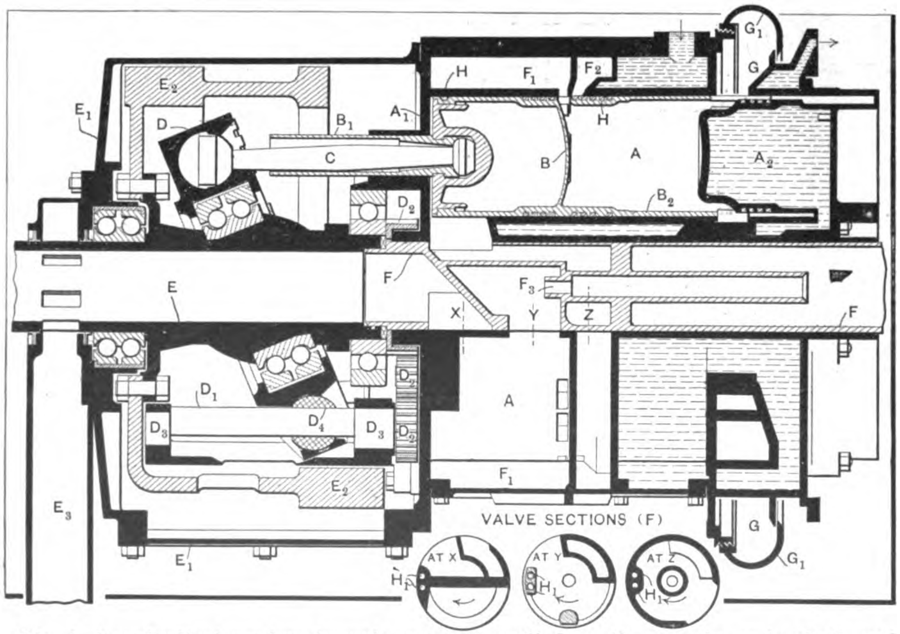

Fig. 2—Longitudinal section through one of the cylinders, through the main shaft, and through the anchorage device, of the Leslie Walker 5-cylinder 2-stroke "wobble-gear" gasoline engine.

Owing to the small angular movement of the connecting rod C it is possible to utilize the front ends of the cylinders A as pumps for feeding the combustion chambers. This is done by fitting each piston B with a tubular piston rod B^1, inside which the connecting rod is free to move, and by fitting a front cover A^1 on each cylinder with a sleeve portion for the piston rod B^1 to slide within. An unusually effective air pump results, since the piston B can be made virtually to sweep out the whole contents of the front end of the cylinder, and to draw in a full charge of air during each succeeding stroke. This construction, however, involves a closed type of piston in which the piston head is no longer cooled by open communication with the atmosphere as in ordinary cases. To overcome this objection, however, it is proposed to imprison within the hollow piston a small quantity of oil, the idea being that this will act as a conveying medium whereby to equalize the temperature of the entire piston, thus enabling its heat to be imparted to the fresh charges of air and to the cylinder walls.

The next matter of importance is to recognize that the long sleeve F, which engages with and rotates with the main shaft E, constitutes a rotating sleeve valve for placing the pump chambers in communication with the hollow shaft E and its stationary feed pipe E^3, for subsequently placing the pumps in communication with the combustion chambers, for introducing the liquid fuel into the air charges and for feeding oil to the reciprocating pistons. In Fig. 2 this sleeve F is purposely shown out of its proper position in relationship to the positions of the other moving parts, but this has been done in order to include a good view of the internal construction of the sleeve—the shape of which is still further made clear by the three transverse valve sections which will be observed at the bottom of the drawing.

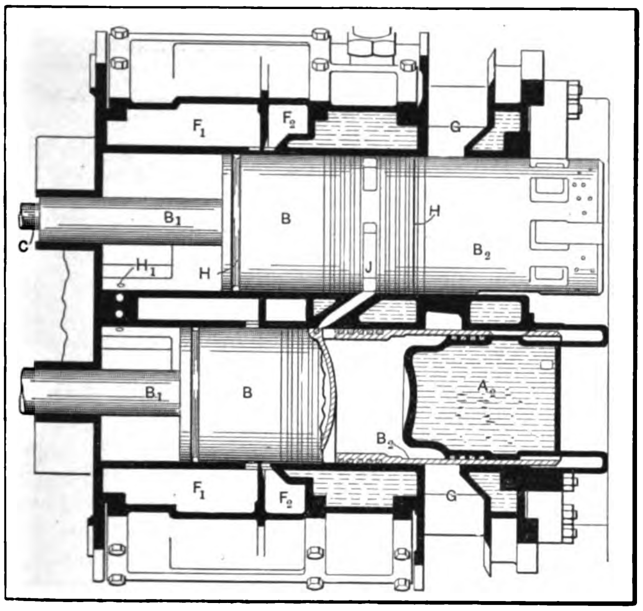

Fig. 3—Longitudinal section through two adjacent cylinders of the Leslie-Walker gasoline engine, indicating the proposed scheme for automatic ignition

A little study of the drawings will show how the valve F places each pump cylinder in open communication with atmosphere through the pipe E^3 during each suction stroke of the piston, and then causes the air to be delivered into the large space F^1, which is formed around the lower ends of all five cylinders A as well as into the separate small passage chambers F^2 that lead to each of the five cylinders. All the pumps are more or less continuously feeding into the large chamber F^1 and this they are intended to do in such a way that the air is carbureted by means of a petrol spray jet situated at F^3, although not shown in the drawing, while, on the other hand, pure air alone is fed consecutively into each of the five smaller chambers F^2 just at the moments when a scavenging air charge is required for exhausting the burnt gases out at the rear ends of the combustion chamber into the common annular exhaust passage G.

Coming now to the control of the combustion chamber, it will be observed that a large water-jacketed cylinder head A^2 is provided for each cylinder, very much as on the "Silent Knight" type of engine, and that the piston B has a long extension sleeve B^2, which fits in beween piston rings on this cylinder head member A^2 and the cylinder wall proper. Ports are cut in the sleeve B^2 close up to the head of the piston proper B and also near the opposite end, the former serving to act in conjunction with similar rows of annular ports leading from the chambers F^1 and F^2 through the cylinder walls, and with other open ports through the cylinder walls into the exhaust chamber G. Hence the actual control of the fresh charge into the combustion chambers, and of the exhaust gases away subsequently, is brought about by the sleeve B^2 alone, its action being, initially, a moment before the completion of the firing stroke to allow pure air to rush in from the chamber F^2, displacing exhaust gases through the port just previously opened to the exhaust, and, secondly, a moment later, to open up communication with the chamber F^1, allowing the fresh charge to be admitted prior to the ensuing compression stroke.

Quite one of the most essential features of the design is the shape of the chambers F^1, F^2 and G in the immediate neighborhood of the peripheral ports leading from them through the walls of the working cylinders. Fig. 4 clearly demonstrates the manner in which the gases are compelled to set up a swirling action in a plane at right angles to the axis of the cylinder itself. The idea, therefore, is to prevent these gases from passing along with any rapidity direct from end to end of the cylinder in a manner that would allow admixture of the fresh combustible charge with the cushioning air charge and with the old mass of exhaust gases, and in this way virtually to form a compact gaseous piston of each of these three sets of gases, so that stratification may eliminate the well-known drawbacks hitherto encountered with engines operating on the two-stroke cycle.

It will of course be observed from Figs. 2 and 3 that the combustion chambers are water-jacketed as well as the cylinder heads, and that two sets of piston rings encircle the pistons in addition to the rings around the head members A^2. Two other details also call for attention, one relating to the means adopted for lubricating the pistons and the other relating to the adjustable ring G^1 for the exhaust gases. Dismissing the latter first, the idea of the inventor is to be able to dispense with any other exhaust box or silencer by so regulating the endless slot G^1 that a constant flow of gas will issue from the five cylinders, while

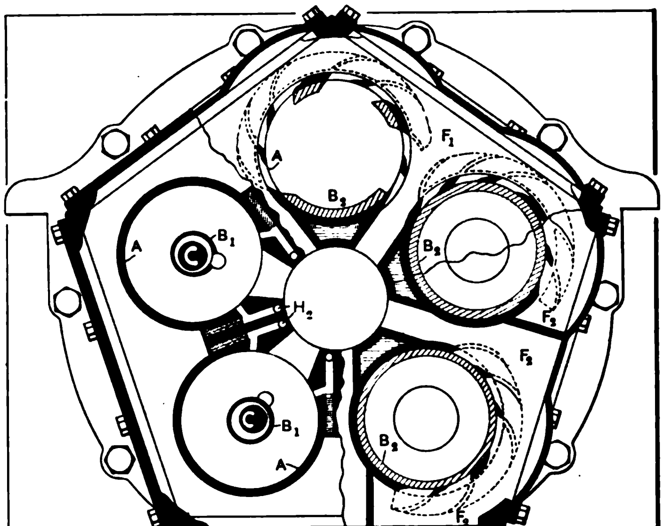

Fig. 4—Transverse sections—taken at X (left), Y (top), and Z (right), respectively—as denoted in Fig. 2

in addition to this a means is provided that may be found useful in controlling the back resistance to the outward flow of the exhaust, thereby varying the compression prior to ignition. As regards lubrication, there are grooves H formed at either end of each piston, these grooves passing around the greater part of the periphery, but not being complete circles. In conjunction with them are feed and return ports H^1 in the valve sleeve F and passageways H^2 in the cylinder castings, the result of these being that oil which is circulated through the ports H^1 in the sleeve F is caused to flow around the grooves at each end of the piston at each dead center from a period representing approximately 20 degrees prior to dead center to 20 degrees after dead center.

Concerning carburetion, we have purposely only cursorily described the means of introducing the fuel to the air charge. Nothing short of experiments can determine whether it is preferable to embody a type of carbureting mechanism into the sleeve F itself, or whether to use an external carbureter of an ordinary type feeding into the supply pipe E^2. In the former case the advantages of the scavenging air charge by way of the chambers F^2 can be retained, and in the latter instance it may, perhaps, prove disadvantageous to have present so large a volume of explosive mixture in case of back fire in the induction. Regarding ignition, since although ordinary plugs would, of course, be provided to begin with, the ignition in each successive cylinder might be effected automatically from a flash obtained from a prior combustion chamber.

A glance at Fig. 3 will reveal the port, J, shown communicating between two adjacent cylinders, the idea there being that the burning gases in the cylinder actually doing its work might be placed in communication with the next cylinder about to fire and thus transfer the ignition continuously around the entire ring. Details of timing, of lag, and so forth necessarily render it impossible usefully to indulge in much surmise in advance on this particular point. A close examination of the views will show several points worthy of notice.

Permanent Wind Shield

THE FEATURE OF THIS MINIATURE TORPEDO BODY DESIGN AS APPLIED TO A MERCER CHASSIS IS TO MINIMIZE WIND RESISTANCE, BY GEO. J. MERCER

THE accompanying illustrations show the picture effect and the working instructions of an entirely new feature in body designing, i. e., the incorporating of the wind shield on the body as a part of the permanent structure. This idea is quite an easy one to apply; it affords good protection during inclement weather in addition to accomplishing the usual functions of a windshield, and, with a transparent portion at the top, it protects the occupants and permits the driver to see ahead. Also, as the illustrations in Figs. 1, 2 and 3 show, the true non-wind resisting effect can be gained by sloping the sides and top of the shield from the engine hood, and this will have, as the illustration shows, the effect of dividing the wind and throwing it off to the side, thereby minimizing effect of wind that actually strikes the glass.

The body is designed for and is shown mounted on a Mercer chassis with 116-inch wheelbase. The front seat on the left side is shown offset back and the door for entrance to the tonneau is on the right side only. A small seat for a mechanician is located on the left side on the runboard. The capacity of the body is for four adults inside and with the additional carrying space in the torpedo stern it makes a snappy car for long touring and the illustration shows the trimming or upholstering plain without tufting. This type of body will look well finished in this manner, and beside the smooth-trimmed body does not hold the dust as the plain surface eliminates the creases.

The important measurements are indicated by figures and the construction is the wood framing and metal panel, the framing is indicated by the dotted lines. As the body is designed the fore-door is left off; should it be desired by a patron, it will be a simple matter to attach a fore-door, and, when the same is being arranged, it will also be proper to consider whether or not it is to be so fitted that it may be removed. While it is admitted that fore-doors are of decided advantage, it remains to be seen whether or not they will prove too warm for Summer use, but it is quite an easy matter to utilize the "Dutch" plan so that the door can be unhinged at will.

Communications

AN ENGLISH RACING EXPERT GIVES HIS VIEWS ON THE VANDERBILT RACE AND COMPARES IT WITH SIMILAR AFFAIRS ABROAD, WHICH HE SAYS ARE MUCH BETTER MANAGED

What a British Racing Driver Saw at the Vanderbilt.—Exactly how much the promoters received from grand stand letting, trade and other entrance fees matters little; but one fact remains and stands clear—the embellishments of the race were conspicuous by their absence. Not a sprig of greenstuff, not a particle of bunting to adorn the weather-stained boards of the grand and press stands. We must not thank the officials who presided over the starting and stopping of the race for its interest; this was provided by the man who paid the piper, and the tune he called was good and gave those who journeyed to Long Island as fine a day's entertainment as they could wish to see.

In a European race meeting the grand stand is covered with bunting and gay festoons. From the tops of the stands fly the flags of all nations, which give a general holiday appearance to the whole gathering. The military is called out to patrol the road and even the color of their uniforms is a relief to the seething masses of people. Automobile races are not conducive to gay colors on the part of the spectators and the early hour of the start necessitates heavy wraps, as comfort is more studied than outside show.

On all sides it is admitted that from a spectacular point of view the race was a great success, the speeds attained phenomenal, the control of the course at dangerous points lamentable, and the condition of the corners bad. A cemented parkway is ideal from a racing point of view as compared with ordinary dirt roads, but level straightaways smooth as a billiard board are less necessary than good surfaces at the corners.

The homogeneity of the surface at the turns was greatly disturbed in the practice on the days preceding the race, but sufficient time remained to remedy this. On the night before the race the corners were quite two inches deep in dust and loose stones, and some idea of how they were on the day of the race can be seen from photographs taken as the racers struck them.

If a man wishes to take his life there is nothing to prevent him throwing himself in front of a locomotive and hurting nobody but himself, but to think that they deliberately cross a course while an automobile race is in progress in a cloud of dust to see the agonies of an injured contestant is beyond all understanding. The words of the acting Mayor of New York will be voiced by everyone interested in the sport of racing. He said, "I believe that the Vanderbilt Cup race should be regulated. Under the present condition it is a menace. These races should be restricted because the danger involved is too great. I do not mean that all automobile races should be stopped, but when the question of inadequate protection arises and when the lives of the contestants are endangered something should be done."

These last few words strike the right keynote. The lives of the foolhardy spectators who venture on the course are of little value compared to those of the participants; the former go on the course at their own risk, and, further, have no right there, consequently cannot claim any sympathy, whereas the competitors are entitled to a free road, and if any accident happens to them through trespassing of the spectators it is impossible to say what further damage may be done through the machine running amuck at about 60 or 70 miles per hour.

The old adage of "*Væ Victis*" is as applicable to-day as it was in the days of the gladiators, but at any rate the vanquished then had equal chance with the victors and fair play. The race just run ended in a victory by the close margin of a few seconds and as the second man actually hit two spectators who were on the course it cannot be estimated how much Dawson on the Marmon was retarded, but anyone can imagine the shock to any human being's *sang-froid* after mowing down his fellow-creatures.

Tales are told of soldiers who before a battle are as nervous as children, but the moment the first shot has been fired are transformed into fiends incarnate, willing to brave anything and to court death at any moment. The same cannot be said of a motor racer; as long as he has a clear road his nerve stays with him, but as soon as the course is encroached upon by the public the fear of hurting somebody robs him of his nerve. The nerve of an automobile racer is the most precious thing he has; we have heard of men driving to victory after an eye, a leg, or an arm has been put out of use, but never after a man has lost his nerve. A case happened in Italy in one of the big road races there. A young amateur started full of hope of victory and ran well for three circuits of forty miles; but at the end of the fourth circuit after seeing the débris of four wrecks strewn along the course he lost all his nerve and wanted to stop, and give up. His friends persuaded him to continue, which at last he did. Three miles further he struck a large mile stone and was instantly killed, although the road was perfectly straight at the spot.

The less said about the press accommodations the better; the announcer's enunciation was clear, but the information was meager.

At the pits, for the most part, bungling and confusion were responsible for the loss of valuable time to such an extent that expeditious work is worthy of special note. The Benz team had a system of tire changing that others might copy with advantage. An eight-foot lever jack was placed under the axle of the car the moment it came to rest by one man while another undid the locking arrangement of the demountable rims with a brace. By this time a new tire was handed to him to replace the old one taken off, by simply lifting it; a few turns of the brace to tighten it up, take the jack away, and off again. Mulford, on the Lozier, changed a valve very quickly in full view of the grand stand, and it was fascinating to watch his composure adjusting the points of a new spark plug. The lightning change of tire on the Alco at the commencement of the 21st lap was a *chef d'œuvre* and the slightest mistake at this point would without doubt have cost him the race.

The foreign method of adjustments seems better than that employed during this race. The pits are manned by assistants to hand out to the driver and his mechanic what they require, but are not allowed on the course at all, everything having to be done by the contestants themselves, in which case each man has an equal chance with the others, the rapidity of work depending, as it should, upon the skill of the men and not on the length of the pocket of the entrants.

It is almost unnecessary to allude to the corners, where the sensation-mongers flocked. Of course, it is only natural that where there is greatest excitement there is bound to be the largest attendance; this being so, the patrolling at these points should be adequate to prevent the crowd from overflowing the course. A suggestion might be offered after last week's experiences. Besides the boards that were put at the turns (these should be much longer), wire screens about 15 feet high should be erected; they would protect the spectators from the showers of stones and be an additional prevention in keeping people off the course. No one should be allowed within 20 feet of the danger zone and the police empowered to arrest anyone crossing the course, treble the police at the danger spots and remove all wreckage as soon as an accident happens, pad the wooden structures erected at the turns with hay so that if anyone is thrown against them there will be a chance of them striking something soft to deaden the impact.—M. J. H., London, England.

An Ideal Automobile

THAT THE AVERAGE AUTOIST IS HARD TO PLEASE IS FEARED; PERHAPS THE IDEAL AUTOMOBILE AS HERE SUGGESTED WILL ACCOMPLISH THE IMPOSSIBLE

MATHEMATICIANS would say that the ideal automobile would have in its make-up the square root of mean square of all the good points that are to be found in all the automobiles that were ever made; each autoist would argue for a car that would meet with his approval, and in trying to settle upon just what he would approve of he would be sure to exclude everything that ever gave him any trouble at all, especially if there was a cost question to be considered.

As an ideal proposition, however, it takes a "wag" to firmly grasp the situation, and the following is one wag's version of the qualities that an ideal car should hold in the hollow of its horny hand.

A Wag's Version of an Ideal Automobile

It would:

(a) Cost nothing to run.
(b) Settle for the tire bill.
(c) Execute the road hog.
(d) Snub the joy rider.
(e) Never go astray.
(f) Improve the roads.
(g) Lay the dust.
(h) Chastise the chauffeur.
(i) Manufacture gasoline.
(j) Improve lubricating oil with age.
(k) Persuade the farmer to love the automobile.
(l) Subdue the politician who thinks he can frame wise automobile laws.
(m) Keep water out of the gasoline.
(n) Side step punctures.
(o) Be gearless.
(p) Pipe the latest air instead of making a noise.
(q) Put a conscience in the anatomy of the repair man.
(r) Clean itself.
(s) Dodge the neighbor who wants to fill the spare seat in the tonneau.
(t) Keep up to the latest style without having to dress up in a new body each year.
(u) Clear the roadway ahead, eliminating the need of a horn.
(v) Light the way o'nights.
(w) Keep it's own brass work shining.
(x) Get along in cold weather without freezing up.
(y) Go like the wind.
(z) Stop in its own length.

Dont's

INJUNCTIONS COVERING A VARIETY OF SUBJECTS BEARING UPON THE AUTOMOBILE FROM THE SEVERAL POINTS OF VIEW AND SAGE ADVICE TO THE MAN WHO WOULD ENTER WHERE ANGELS FEAR TO TREAD

Don't purchase a motor so small that a muffler cutout will have to be used in order to make the power patch out—what you really need is a motor that will deliver the required amount of power cutout or no cutout.

Don't go rushing across space with a screeching muffler cutout as much as to say, "Here I come (a beggar a car-back) out of an obscure past, ready to show the stripes on a new suit of clothing and make myself conspicuous."

Don't try to determine the ratio of alcohol to gasoline—that makes the automobile lead up to the front of a hospital; it is a variable quantity in any case—a very little alcohol does the trick in some instances, especially if it is placed in a certain tank.

Don't argue with the chauffeur about what he is to do—get one that will know without having to be persuaded.

Don't try to acquire all the cardinal virtues in a chauffeur; he will shine too brilliantly in your presence if you get him.

Don't be satisfied with a man who says he is thoroughly capable, especially if he is good at making excuses.

Don't take excuses—demand that the automobile be in serviceable condition, or learn the reason why.

Don't expect the automobile to be in serviceable condition if it is old and is in need of an overhauling; it is cheaper in the long run to give it the periodical overhauling that will offset depreciation.

Don't forget that it is in just as bad taste to toot the horn of your automobile continuously as it is to toot your own horn—let up.

Don't sign contracts to leave your car for an indefinite period with a second-hand dealer.

Don't believe a man can easily sell a second-hand auto.

Don't agree to pay for all sorts of extras for car selling. Agree upon either a fixed sum net for the car or place your reserve on it and allow a commission.

Don't expect to obtain the same price for the car after it has run as it cost new. If you intend to sell the car immediately after you have bought it don't run it.

Don't expect people to think that after a car has only run 1,000 miles it is always a journey abroad that causes you to sell it; they may blame the car.

Don't buy a second-hand car by the outside looks; get someone who knows to look inside.

Don't run away in case you have an accident. If you are to blame you will be treated worse if you run away than if you stop; if you are not to blame you will be if you decamp.

Don't use force on nuts; patience, persuasion and kerosene are infinitely better.

Don't drive past a sign post if you don't know the way. Stop. It is quicker than to go on and wonder if you are right and come back 20 or 30 yards on the reverse, especially at night.

Don't spirit your good intentions away while you hesitate long enough in front of a road house to beat your will into abject submission—drive right along.

Don't pose on the pinnacle of success; some one will come along and pull the pinnacle out from under you.

Don't strap yourself to the idea that the last good task that you may have performed is the record—the real record is as yet nestled on the bosom of future possibilities.

Questions That Arise

CONCERNING THE THEORY OF WIND RESISTANCE; LOCATING LOSS OF PRESSURE IN PRESSURE-FED CARS; FORMULAE FOR SUSPENSION SPRING DESIGN; CAUSES OF HOT MOTORS, ETC.

[246]—What is the force per square foot pounds as compared with the velocity of wind?

A formula often accepted is $P = 0.005V^2$, in which V is the velocity in miles per hour. It was put forward for surfaces in use in windmill practice. Smeaton's table is as follows:

Velocity and Force of Wind, in Pounds per Square Inch

Miles per hour.	Feet per second.	Force per sq. ft. pounds.	Common Appellation of the Force of Wind.	Miles per hour.	Feet per second.	Force per sq. ft. pounds.	Common Appellation of the Force of Wind.
1	1.47	0.005	Hardly perceptible.	18	26.4	1.55	Very brisk.
2	2.93	0.020	Just perceptible.	20	29.34	1.968	
3	4.4	0.044		25	36.67	3.075	
4	5.87	0.079	Gentle pleasant wind.	30	44.01	4.429	High wind.
5	7.33	0.123		35	51.34	6.027	
6	8.8	0.177		40	58.68	7.873	Very high storm.
7	10.25	0.241		45	66.01	9.963	
8	11.75	0.315	Pleasant brisk gale.	50	73.35	12.30	
9	13.2	0.400		55	80.7	14.9	
10	14.67	0.492		60	88.02	17.71	Great storm.
12	17.6	0.708		66	95.4	20.85	
14	20.5	0.964		70	102.5	24.1	
15	22.00	1.107		75	110.	27.7•	
16	23.45	1.25		80	117.36	31.49	Hurricane.
				100	146.67	49.2	Immense hurricane.

Other formulæ put forward are:

Professor Martin, $P = 0.004V^2$

Whipple and Dines, $P = 0.0029V^2$

At 60 miles per hour these formulæ give a pressure per square foot of 18, 14.4 and 10.44 pounds, respectively.

[247]—How to locate loss of pressure in pressure-fed cars.

The most vital part of a pressure system is the relief valve, and it is more often due to trouble here that the pressure will not hold. Nothing is more annoying than to continually have to pump up pressure by hand owing to a leak. If exhaust gases are used a strainer or filter should be placed between the exhaust outlet and the valve, otherwise all impurities such as carbon and burnt oil will clog it or find their way under the seats of either of the mushrooms. The component parts of this valve are two small checks in the nature of a back pressure and safety valve combined with springs to hold them in tension on their seats and regulating screws. The amount of pressure passing into the tank can be regulated from below and the point at which the pressure is released is altered by turning a screw above.

A pressure of from two to four pounds is necessary to give the required head of gasoline in cars where the tank is placed at the rear. The filler cap being loose or the washer defective will cause a leak; the best material for such washers is leather, and a spanner should be used to tighten the cap. If the oil is under pressure and in the same circuit as the gasoline a leak at the oil tank cap will prevent the gasoline from reaching the carbureter, and the same effect will be produced if the oil runs out; then the pressure will go into the tank and escape through the lubricator. In the types of relief valves where a steel ball is used this should be taken out often and cleaned, otherwise it will become pitted and the smallest quantity of this is sufficient to cause a leakage.

It should not always be imagined because gasoline does not flow at the carbureter that the pressure is at fault; the first thing to look at is the level of the gasoline in the tank. This may sound too trivial to mention, but many an autoist has gone over his car from one end to the other only to find that a few gallons of gasoline would have remedied his troubles.

The pipe in some pressure tanks is fed from the bottom to the top, and while climbing a hill with little gas in the tank it flows toward the rear and uncovers the pipe, leaving it nothing to feed from and allowing all the pressure to escape.

[248]—What are the formulæ for the correct design of suspension springs?

The method often followed is one of trial and error. For single springs the following by D. K. Clarke is often used:

$$\text{Safe load in tons} = \frac{BT^2N}{CS}$$

in which

B = width of plates.

T = thickness of plates in 1-16 inch.

N = number of plates in spring.

S = span of spring in inches.

C = constant = 11.3.

To determine the deflection in inches per ton-load the following formula is sometimes used:

$$D = \frac{L^3}{CBT^3N}$$

where

D = deflection in inches per ton of load.

L = span of spring in inches.

C = constant = 40,000 for single springs.

= 20,000 for double springs.

T = thickness of plates in inches.

N = number of plates in the spring.

When the springs are first put to work they will probably take a certain set and this must be allowed for.

[249]—What are the causes of overheating of a gasoline motor?

Insufficient supply of water.

Failure of the water pump, caused through breakage of the spindle, shearing of the key holding vanes to axle.

Air lock in the water system.

Slipping clutch.

Excessive lubrication or bad quality oil.

Wrong timing of the exhaust valves or too little lift of same.

Car being too low geared for speed of the engine.

Close proximity of the water circulating pipes to the exhaust manifold.

Presence of grease or other foreign matter in the circulating system.

Too much gasoline in the mixture.

Running with the ignition retarded.

Fan belt slipping.

Pump running too fast, causing the water to accumulate at the top of the radiator and pass away out of the overflow before it has time to pass through the radiator.

[250]—What is the solution and force of current used for nickel plating?

The solution mostly used is made from the double sulphate of nickel and ammonia, with the addition of a little boracic acid under certain conditions.

The double salt is dissolved by boiling, using 12 to 14 ounces fo the salts to a gallon of water. The bath is then diluted with water until a hydrometer shows a density of 6.5 degrees to 7 degrees Baumé. Cast anodes are to be preferred, as they give up the metal to the solution more freely. Anodes should be long enough to reach to the bottom of the work and should have a surface greater than that of the objects being plated.

The current should be moderate. Voltage may vary from 3.5 to 6 volts and from 0.4 to 0.8 ampere per 15 square inches of surface of the object. Zinc requires about double this current. A nickel bath should be slightly acid; an excess of alkali darkens the work and an excess of acid causes peeling.

COMMUNICATIONS FROM READERS MAINLY ALONG TECHNICAL LINES; CORRECT SHAPE OF PISTON RINGS; TO STOP OIL LEAKS FROM BASE CHAMBERS; HOW TO INSTALL A CONSTANT-LEVEL LUBRICATOR; NEW TWO-CYCLE MOTOR; MAKING A HEADLIGHT BRACKET

Cap Shape of Piston Rings

Editor The Automobile:

[2,389]—Having been informed on many valuable points in automobile design by your paper, I am taking the liberty of asking you a question.

If a piston ring is turned and cut to make a true arch with its outside circumference before being compressed to fit into the cylinder, does it form a true circle when compressed in the cylinder, unless the side where the ends of the ring meet have been made thinner? To be more explicit should the piston ring not appear when in perfect finish as in B (Fig. 1)?

Ardmore, Pa. E. Radifer Stancliff.

It is common practice to make piston rings as you suggest, as when the ring is made a true circle within its inside diameter there is a likelihood of its expanding in a more or less oval form and there are the chances of the cylinder being worn oval before the rings have worn to a circular shape. The outside circumference should be a perfect circle with the slit closed. Another method employed is to take a concentric ring as in A, and place it round the extension of a vise in the manner shown in the diagram. A pien hammer is used (C) and blows are struck on the ring at a true tangent point and not, for instance, at b; otherwise the result will be a broken ring. This method of tapping at every 3-8 of an inch causes a small indentation as shown and gives them a perfectly uniform spring. The blows should be harder opposite the slit and soft near the slit.

To Stop Oil Leaking

Editor The Automobile:

[2,390]—I have constant trouble to keep the oil from running out of the joint between the two halves of the base chamber of my engine. Can you suggest anything to remedy this trouble?

Portland, Me. P. F.

You can either cut a piece of brown paper to the shape of the face, cover it with a thin coat of white lead, turn the bolt up tight, and it should hold; but every time you break the joint you will have to make a fresh one.

Another method is to cut a small groove around about 1-8 inch deep and insert some string asbestos in it, as in Fig. 2. With the pressure this will tighten up and act as a washer; at any time you have to take the motor apart all that is required is a new piece of asbestos string.

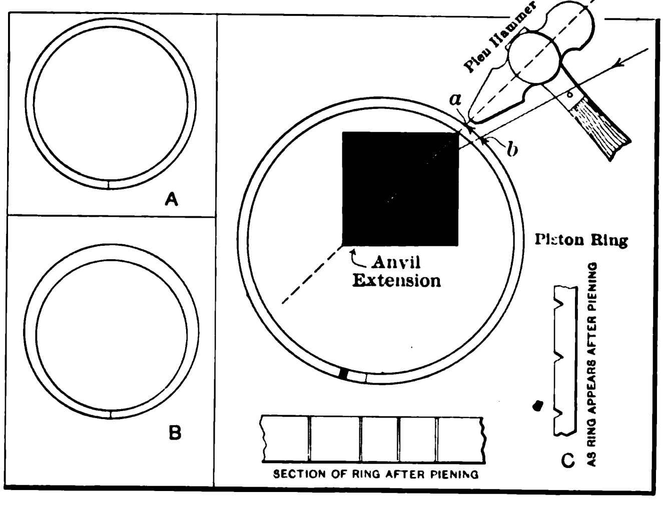

Fig. 1—Method of piening piston rings

Installing a Constant Level Lubricator

Editor The Automobile:

[2,391]—I want to install on my Mitchell 1910 car a lubricator for purpose of maintaining a constant level in crankcase. Only available place to hang the tank is about 17 inches above level of oil in crankcase. Tanks to be about 4 in. x 12 in. hung horizontally. What size pipe shall I use to carry oil to crankcase and must it be choked? If so, where? How far below the desired level should outlet end of pipe be placed? Will appreciate any advice you can give me.

Mineral City, O. J. Ira Davy.

An easy method of maintaining a constant level in the crankcase of your engine can be readily seen by referring to Fig. 4. In the existing plug holes 3-8 inch standpipes are fitted to the correct oil level as shown, and from these 3-8 inch copper pipes carry the oil to an ordinary gear pump. This should be attached to the base chamber, if possible below the level of the oil, and a shaft run from it to which is attached a pulley wheel in line with the existing lubricator wheel. The belt can then be utilized to run both without doing away with the existing oiling system to the bearings.

The oil is then led from the pump as the sketch shows to a sight lubricator on the dash and passed through a sight feed to a reservoir situated on the dash or some other convenient place above the crankcase, from where the oil is returned to the crankcase by two pipes in its upper part. A tap should be fitted under the reservoir to cut off the supply if necessary during running and when the engine is stopped.

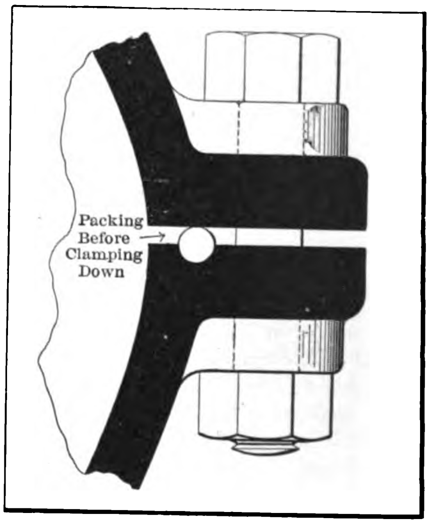

Fig. 2—Making an oiltight joint for two base chamber halves

Running Electric Light Off Magneto

Editor The Automobile:

[2,392]—I am a reader of your magazine, The Automobile, and would like to ask for some information in regard to electric lights. I have a Haynes car with low-tension magneto which runs through a condenser and would it affect the running of the car on the magneto, and if not would it be best to connect before or after the current goes through the condenser, and please describe as near as possible the size lights, etc., for such an arrangement. Find enclosed self-addressed letter for return.

Thanking you in advance, I am,

Gonzales, Tex. C. A. Hoskins.

You cannot use the magneto on your car for electrically illuminating it. You must either use a storage battery or small dynamo.

Left or Right Hand Running Motor

Editor The Automobile:

[2,393]—I have pleasure in handing you a sketch (Fig. 5) showing a method of altering the timing of a four-cycle engine to allow it to run in either direction.

A is a gear free upon the crankshaft and B is a sprocket wheel also free upon the crankshaft. *C* is a jaw clutch, yet it can be slid back and forth up the crankshaft upon a four cut keyway. The gear *A* and the sprocket *B* are set in such a way that when the engine is on dead center the jaws *I* and *K* are at the upper side of the shaft and exactly opposite. Let clutch *C* be engaged with gear *A* and the valves are timed; run engine clockwise, looking from the front. The sprocket *B* runs in the opposite direction, but always passes at the bottom and top of the shaft.

Now, if you stop the engine and disengage the jaw clutch *C* from gear *A* and at the same time apply a brake to the camshaft, turn the engine over in the opposite direction until clutch *C* matches jaw *K* and engage them, you will be able to run the engine in the opposite direction counterclockwise.

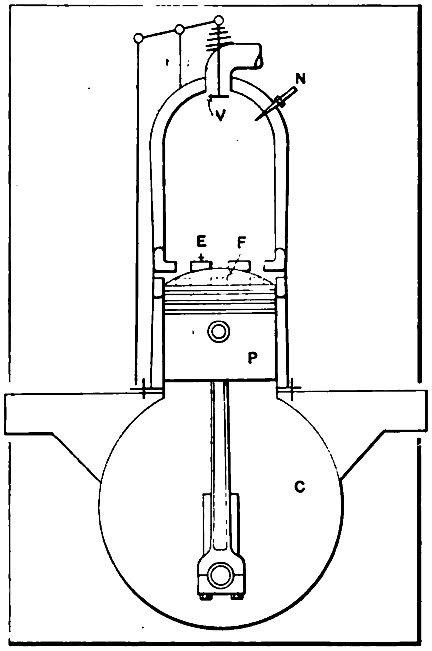

Fig. 3—A new two-cycle motor

Keep in mind that while you are turning the engine over to engage *C* with *K* the camshaft has been kept in the same position as it was when engine was stopped.

Although now the crankshaft is running in the opposite way the camshaft is not, and therefore the valves are opened in the same rotation.

New York. Subscriber.

A New Two-Cycle Motor

Editor The Automobile:

[2,394]—I should be glad to have the opinions of your readers upon an idea I herewith send you upon something new in the two-cycle line (see Fig. 3).

Referring to sketch: V represents exhaust valve; N, fuel injector nozzle; E, a series of exhaust ports; F, a series of inlet ports. The action of the motor is as follows:

Piston P on the downward stroke uncovers exhaust ports E, allowing the hottest gases to escape through them. At this point the exhaust valve V opens simultaneously with the inlet ports F, thus allowing the charge of cold air that has been previously drawn in crank case to fill the space above the piston and to force out the charge that has been burned. Exhaust valve V remains open until the piston has returned to a position on its upper stroke, where it has displaced the contents of the combustion chamber, thus affording perfect scavenging of the burned gases. No fuel enters the cylinder until all ports are closed and the cylinder has entrapped a charge of fresh air.

Cleveland. A. E. P.

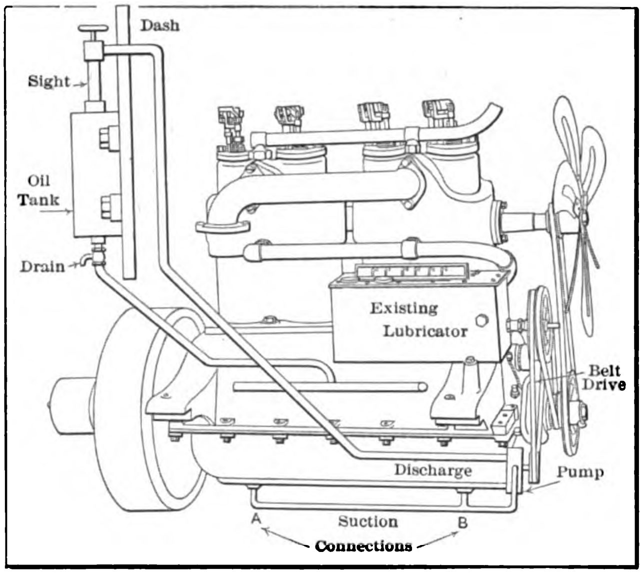

Fig. 4—Supplementary oiling arrangements to maintain constant level of lubricant in base chamber

Too Much Gasoline in Float Chamber

Editor The Automobile:

[2,395]—As a reader of your publication will you advise me through your columns what caused the following difficulty with my carbureter?

Car running smoothly, but obliged to stop engine half-way up a steep hill on account of slipping clutch, and on trying to proceed after ten minutes' halt, the engine declined to respond to cranking of the motor.

Wiring and ignition were found in order, but I noticed gasoline was dripping from carbureter, probably due to flooding, possibly caused by the car standing on the steep grade. Opened petcock beneath the carbureter and after closing same, allowed engine to remain idle for a few minutes, whereupon cranking the motor vigorously, she started off all right.

Was this due to the car standing on a steep grade? If so, why should carbureter flood? Same is gravity fed and was well filled with gasoline at the time, as observed through the glass bowl of the Stromberg.

James W. Worth.

New York.

The cause may be that the adjustment of the level is incorrect, allowing too much gasoline into the float chamber; not sufficient, however, to cause an overflow when the car is standing still, but

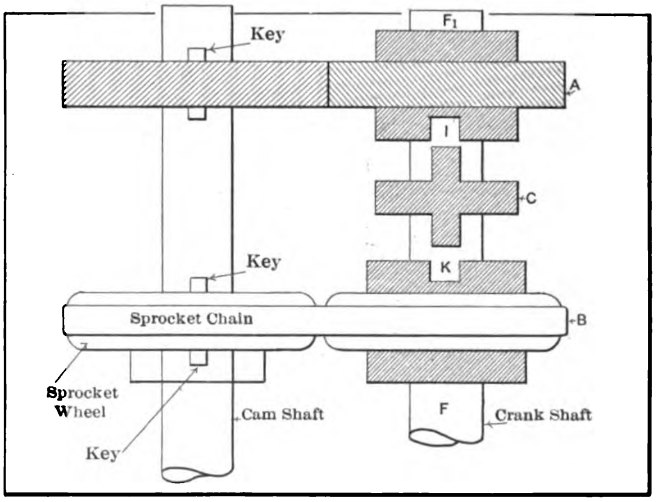

Fig. 5—Arrangement for altering timing of a four-cycle motor to permit it to run either way

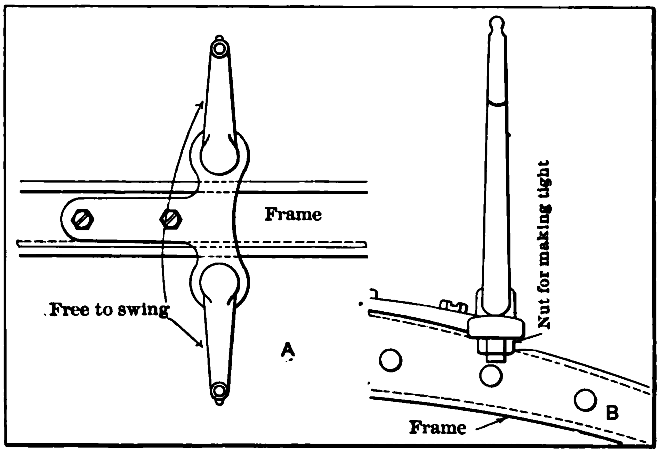

Fig. 6—Headlight bracket to fit any lamp

as soon as it is inclined and allowed to stand still on an upward grade it overflows the jet, causing the flooding.

The layback of the needle valve while the car is standing still on an up-grade will cause an overflow at the jet if the seat of the needle is not a perfect fit on its seat or any small impurity finds its way underneath same, rolling back owing to the inclined plane of the car.

The effect of flooding will not be noticed as long as the car keeps going, as the extra amount of gasoline will be used up by the extra work called upon the motor to perform; in fact, it will improve the running of some cars to place the float chamber in front of the jet.

Headlight Brackets to Fit All Lamps

Editor The Automobile:

[2,396]—What method would you suggest for making lamp brackets to fit several types of cars and different lamps?

South Amboy, N. J. Inquirer.

The accompanying sketch (Fig. 6) shows a method of making headlight brackets to answer your requirements. It is made in three parts, the T-piece to be bolted to the extension of the dumb-iron of the frame in front of the radiator. The side arms that hold the lamp fit into the two holes and are held securely by a split washer and nut; by undoing the nuts the arms can be adjusted to fit any lamps of ordinary size. If extra large lamps are used, new arms can easily be made.

Notable Speed in Voiturette Race

Editor The Automobile:

[2,397]—In the recent Voiturette race in which the times were so phenomenal it is very surprising that such small engines could develop such speed. Kindly inform me of sizes of respective engines?

Madison, Wis. A. T.

The winner's average speed was 56 miles per hour over a circuit of 23.7 miles, which had to be covered 12 times to make up the 284 miles. The fastest lap was made by the Lion Peugeot driven by Goux in 24 min. 33 sec. Zuccarelli's time for the entire circuit was 5 hours, 4 minues, 50 seconds. The sizes of the engines are as follows:

Car	No. Cyl.	Bore	Stroke
Tribel	4	65 mm. (2 9-16 in.)	180 mm. (7 3-32 in.)
Hispano-Suiza	4	65 mm. (2 9-16 in.)	200 mm. (7 7-8 in.)
De Bezelaire	4	69 mm. (2 23-32 in.)	110 mm. (4 11-32 in.)
D.S.P.L.	4	65 mm. (2 9-16 in.)	140 mm. (5 33-64 in.)
Lion Peugeot	4	65 mm. (2 9-16 in.)	260 mm. (10 1-4 in.)
Lion Peugeot	2	80 mm. (3 5-32 in.)	280 mm. (11 1-32 in.)
Calthorpe	4	65 mm. (2 9-16 in.)	170 mm. (6 45-64 in.)
Calthorpe	4	65 mm. (2 9-16 in.)	150 mm. (5 29-32 in.)
Corre Licorne	1	100 mm. (3 15-16 in.)	300 mm. (11 13-16 in.)
Corre Licorne	1	100 mm. (3 15-16 in.)	250 mm. (9 27-32 in.)

1911 Models Knight Daimler

NOVELTIES IN DESIGN INCLUDE ADOPTION OF WORM GEAR DRIVE, INCLINED MOTOR AND SPECIAL LUBRICATION SYSTEM

IN the particulars of new models of the English Knight Daimler that have appeared recently there are several new features worthy of note, particularly in the 12 horsepower model. The cylinders are cast en bloc with a bore of 69 mm. (2 23-32 in.) and stroke 114 mm. (4 1-2 in.). The engine is set in the frame at a considerable angle, sloping rearward, thus saving the uni-

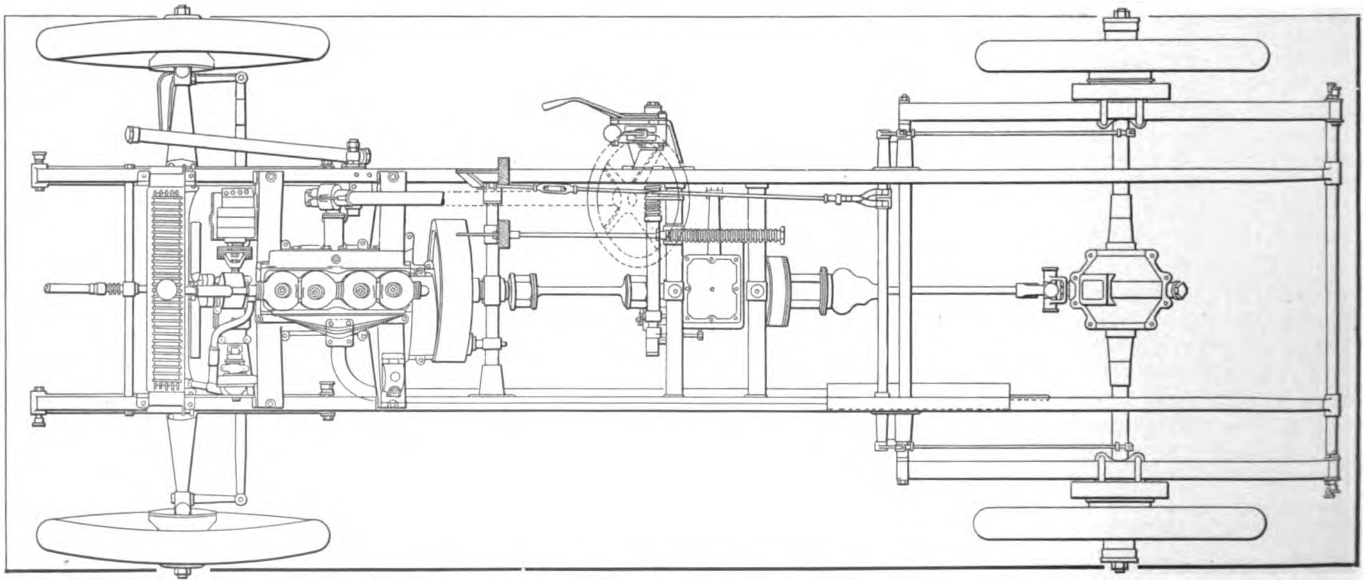

Fig. 1—Plan view of Knight Daimler chassis, showing external clutch spring and double universal jointed shaft between gear box and engine

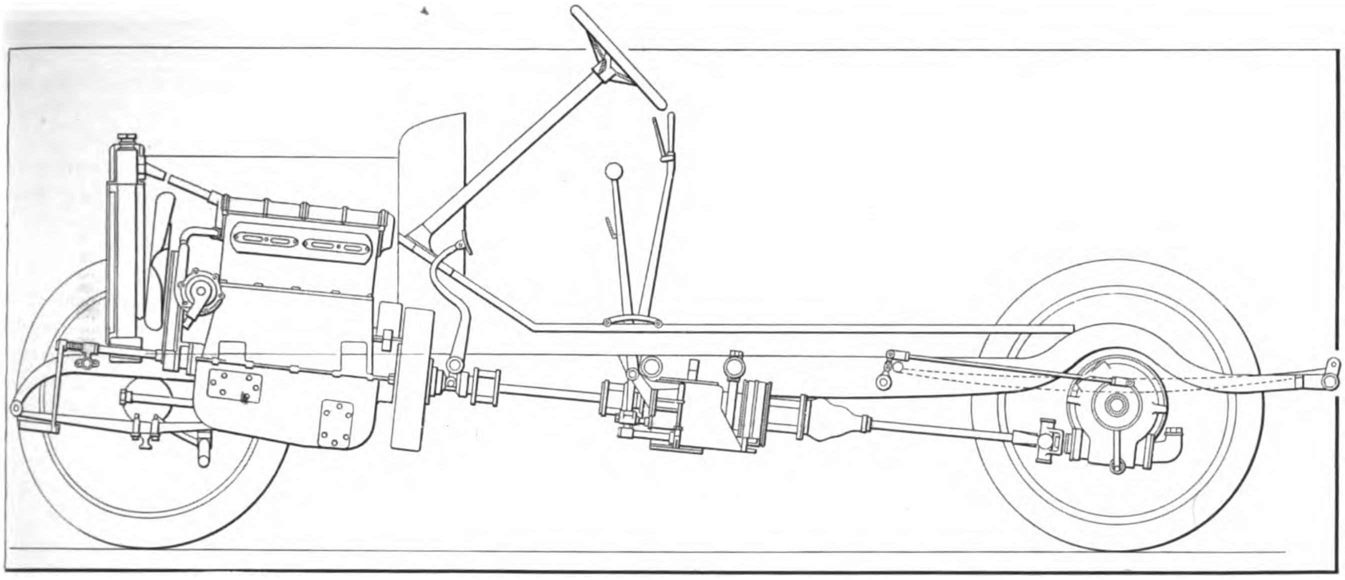

Fig. 2—Side view of Knight Daimler chassis, showing straight line between engine, gear box and rear construction, worm drive and upswept frame

versal joint on the propeller shaft from a great deal of wear. As in usual slide valve practice the exhaust and inlet manifolds are placed on opposite sides of the motor, the designs of which are very clean. Ball bearings are fitted to the crankshaft and there is also a thrust bearing at the forward end of the crankshaft. The chain wheel that drives the eccentric or valve shaft is located at the rear end. The pump and magneto being driven by helical gear from the front end makes these organs very accessible. The carbureter has two jets, and a similar system to that used by the G. & A. (recently described in THE AUTOMOBILE) is employed for the extra air intake, consisting of a series of balls that are lifted from their seats by the engine suction.

The lubrication system on this new 12-horsepower model, says *The Autocar*, is decidedly interesting and ingenious, and is the subject of a special sketch given herewith. A sump is formed at the bottom of the crank chamber, and situated therein is a plunger pump driven by an eccentric off the eccentric or valve shaft. In connection with the base of the pump is an oscillating two-way valve operated from one of the eccentric pins on the valve sleeves, the function of this two-way valve being to open up the pump barrel as required to allow oil to enter on the suction stroke at one side, or, on the other side, to find exit on the pressure stroke to the main oil lead shown in the sketch. The oil from the pump is delivered to a shallow trough at the front end of the engine, and thence gravitates, owing to the rearward inclination of the engine, over the surface of a foundation plate to four main troughs, one under each connecting rod. The surplus oil from the fourth trough finds its way by gravity back to the sump in the usual manner. On each side of the row of troughs is placed a baffle-plate extending along their whole length, so that when the oil from the earlier of the four troughs is splashed out by the connecting rods it runs back on the foundation plate and thence to one of the other troughs. A new feature in connection with this type of lubrication is that the depth to which the connecting rod ends dip into the oil is varied to suit different conditions of running. The foundation plate of the troughs is anchored upon two rods, which in turn take bearing upon four short levers, one at each corner. By these means the troughs can be raised or lowered in their position relative to the connecting rods, the controlling rod of this motion being interconnected with the throttle. When the engine is running at slow speeds with the throttle nearly closed, the connecting rod ends only just reach the oil level, but gradually, as the throttle is opened, the troughs are raised, and, as required by the conditions obtaining at the moment, the engine receives more and more oil. It is claimed, and seems probable, that economy of oil will result from this arrangement, for with fixed troughs the amount of dip allowed to the connecting rods must naturally be sufficient for all and any conditions, resulting sometimes in oil being wastefully used at low speeds when but little is really required. Smoking from over-lubrication is also reduced to a minimum.

The transmission gear arrangements follow usual practice, three speeds and reverse being fitted, with worm drive, the inclination of the crankshaft allowing a practically straight drive from crankshaft to the worm under the back axle.

Digest

EXTRACTS FROM CONTINENTAL JOURNALS ON SUBJECTS ALLIED TO AUTOMOBILE ENGINEERING: KEROSENE MOTORS FOR BOATS—DESCRIPTION OF SABATHE MOTOR—NOISE FROM TRANSMISSION GEARS—COMPOSITION OF BENZOL—INFERIORITY OF PLANTATION RUBBER

Ordinary automobile motors are unanimously condemned for marine purposes, according to the reports made to the "International Congress on the Application of Internal Combustion Motors to Marine Craft for Naval, Commercial, Fishery and Pleasure Purposes." The fact that the kerosene motor has not yet become exclusively adopted for these ends in French waters is ascribed to the unfavorable conditions created by the import tariff. In the recent contest conducted by A. Lumet for the Automobile Club of France, the Sabathe motor was adjudged superior to the competing motors of Danish and American manufacture which have been used by the thousands for fishing boats for a number of years, and also superior to the Aster and the Peugeot-Tony Huber, competing French kerosene motors. The author describes the Sabathe and the Diesel motors, and dwells on the principles of ignition as modified by the nature of the fuel, with special reference to the Sabathe type. If one were to employ kerosene in gasoline motors of high rotary speed and light parts there would be trouble. With an almost constant maximum power output and a gasifier giving a fulminating mixture, this type of motor will not last. The explosion must be tempered by injection of water, but this method for regulating combustion is exceedingly delicate and can be achieved only in stationary practice. Reduction of the compression reduces efficiency. To effect complete combustion of kerosene in a motor of high rotary speed is rendered difficult by the time required for vaporization of kerosene except at high temperatures. Ignition by high-tension magneto is impracticable, as the spark will not burn an unexplosive mixture. The low-tension magneto does better, but a jet of flame is the only really suitable means. As the mixture ignites only with difficulty, there should be an effort for concentrating its molecules by compression up to the point where self-ignition is reached. At this point the flame jet will be necessary to assure precision in the timing of the ignition, and these considerations explain the hollow hot wall ignition chambers or balls with which the "Dan" and the Mietz & Weiss kerosene motors are equipped. Both turn at 400 to 500 revolutions per minute and the mixture is not prepared outside the cylinder. Only the air is compressed and the kerosene is injected at the end of the compression stroke and burns rapidly after self-ignition. In the Diesel motor the air is compressed at the rate of 30 to 35 kilograms per square centimeter, which raises the temperature to 500 deg. or 600 deg. Cent. The kerosene is injected near the dead center, the rule for its injection being determined by the condition that the temperature shall increase as nearly as possible in the same proportion by the combustion as it is reduced by the piston displacement. This feature is termed the isothermic expansion. The injection is then discontinued and the expansion continues adiabatic.

In the Sabathe motor, which functions according to the cycle of mixed combustion, the air is also compressed at the rate of 30 kilos and a temperature of about 600 deg. Cent. is produced. The fuel is injected in two doses. The first portion is injected before the dead center and serves to raise the compression to 40 kilos per square centimeter. The second portion is so injected as to produce a combustion giving substantially constant pressure. But when less than normal power is required of this motor, the second dose is omitted and the first dose burns in that case with "constant volume." The Sabathe motor which was tested by Mr. Lumet had the following measurements: 220 millimeters bore, 220 millimeters stroke, 350 revolutions per minute. The number of cylinders was three. It has been submitted in another form to tests by the navy department, having a bore of 485 millimeters, a stroke of 480 millimeters, four cylinders and 700 effective horsepower at the normal speed of 300 revolutions per minute. It is reversible by displacement of the camshaft while running. It weighs 19 tons, including an air compressor, making its weight per horsepower 30 kilograms. The lower half of the pressed-steel crank casing, comprising the supports for the crankshaft bearings, is mounted on a cast foundation, and the cylinder jackets are bolted to the upper portion of the casing, supporting the cylinders by means of projecting annular flanges, so that the cylinders may be turned around their axes if required. The pressed-steel piston is cooled by spraying from a pump actuated from the crankshaft. To provide perfect tightness of the piston and obviating the danger of fire from escaping gases, the spaces between piston rings is closed by rings of anti-friction metal, and the space below the piston rings is similarly closed, four anti-friction metal rings being used here. The half-speed camshaft actuates the admission and exhaust valves, the kerosene fuel injection valve and the compressed-air valve by which the motor is started. The kerosene flows to a chamber below a valve which is centered around and slides on the discharge needle, and the valve is raised by means of two lugs secured to the needle. When small power is required, the kerosene fills this chamber, and when the needle is raised the fuel is injected and burns at "constant volume." For greater power, more fuel is admitted and passes to above the valve, and when the needle is raised, causing the kerosene in the chamber to be discharged first, the lugs come in contact with the valve and take it with them in their upward movement. And then the kerosene which is above the valve, being subject to pressure from the compressed air, enters into the cylinder where it burns, the progress of the combustion depending upon the profile of the cam, which is designed to produce approximately a constant pressure. Kerosene pumps, one for each cylinder, distribute the fuel. They are actuated by cams and pistons and their discharge is regulated by varying the shape of the cams. Two air compressors are used for this motor, one being operated from the crankshaft and reducing the power of the motor to 650 horsepower, while the other is operated by a special motor. The small Sabathe motor intended for fishing boats developed at the tests 36.9 horsepower and used 0.309 kilograms of fuel per horsepower hour and 0.015 kilograms of lubricating oil. At half angular speed the corresponding figures were 0.399 and 0.028.—*La Vie Automobile*, September 17.

Among the causes of noise from transmission gears, which make the vehicle "sing," a writer mentions the following: Long shafts, ball-bearings, deformation of gears due to the hardening process and not properly rectified, the tangential speeds of the gears, the shape of the gear teeth, the quality of the metal used in gears, shafts and casings, the shape of the casing, the suspension of the casing in the chassis or subframe. The effect of long shafts may be directly one of vibration or it may be the noise due to the less perfect mesh resulting from the bending of a long shaft. It is claimed that ball-bearings take play much more rapidly than plain parallel bearings, and the writer points to the noiseless motors in which parts are moved with much greater speed than in the transmission, but which, nevertheless, make no sound because the bearings are all plain. He proposes to have the subject investigated by building two cars identical in all respects, excepting that the bearings in one should be plain and in the other on the ball-bearing plan. It is claimed that the more the transmission casing approaches the cylindrical form the less sound is emitted, and also that a steel casing "sings" less than one made of light metal. It is suggested to interpose a thin layer of soft metal between the crown of a pinion and the spider or shaft.—*La Pratique*, September 10.

Investigations of the elasticity of rubber derived from varied sources have been begun by Dr. J. C. Willis, director of the botanical garden at Peredeniva, and have already resulted in establishing the fact that rubber which comes from the plantations, whether in Asia, Africa or Oceanica, is inferior to the rubber which grows wild in the same regions in the forests. Its elasticity varies unaccountably, being very good in some cases and very poor in others without it being found possible so far to arrive at any explanation of the variation.—*Omnia*, September 17.

[While all reports relating to the rubber supply, even those apparently best authenticated, must be received with some degree of distrust, owing to the stock manipulations which are constantly taking place in the rubber market, the above report gains interest from the implication it contains to the effect that the plantation rubber in some instances, though these be rare, is found even better than that grown in the forests. Investigation of the causes should eventually lead to a systematic culture by which the plantation rubber may be rendered uniformly superior, and thereafter a rubber famine would become practically impossible and adulteration unnecessary.]

Benzol, now largely used as automobile fuel in Germany, and somewhat in France, is a mixture of benzine, toluene and xylene. The 90 per cent benzol, which is the grade employed for automobiles, contains about 84 per cent. benzine, 15 per cent. toluene and 1 per cent. xylene. The 50 per cent. benzol, which is usually a crude and impure product, contains only 60 per cent. to 65 per cent. of benzine. The specific gravity of 90 per cent. benzol at 15 deg. Cent. is 0.885. Benzol as extracted from coal by dry distillation is a by-product either from the manufacture of illuminating gas or that of coke. In point of fact nearly the entire output of benzol is now derived from the cokeries connected with the steel mills. Here the gases resulting from the distillation are generally utilized for heating the very furnaces in which they are produced and play only a secondary economical part. There is nothing to hinder the removal of all the benzol which they contain. Each ton of coal used in the cokeries yields 4 to 5 kilograms of benzol, which is ten times more than may be obtained by treating the tars from the gas plants.—*Cosmos*.

Among the means discussed for getting high power from a motor by increasing the number of revolutions and thus avoiding an increase of weight, the employment of a fan or air compressor for forcing as large an explosive mixture into the cylinder at high speed as the cylinder is capable of taking in by its own suction at the lower speeds has exerted great fascination over the minds of designers, and recently the designers of aviation motors have taken up the idea. As well understood, the standard automobile motor shows a torque curve shaped as the back of a shad, because it is impossible to draw in as large a charge at high speed as at low speed, and the force of each explosion is reduced in proportion to the amount of fuel consumed in it, granting that the mixture is maintained constant in composition. A motor which would give a straight line torque curve, the power being strictly proportionate to the number of revolutions, is conceivable by two means. Either the charges introduced at the low speeds must be throttled or those at high speed must be forced. When the question is of producing a maximum of power only the latter alternative is of interest. A motor of 100 millimeters bore, which may give 10 horsepower at 1,200 revolutions per minute. should with a successful system of forced admission give 48 horsepower at 4,800 revolutions per minute. Supposing such a motor could be made to operate, as perhaps is possible, it would lack the flexibility which the automobile motor now derives from the very fact that the power does not drop as rapidly as the number of revolutions per minute. For example, on a hill the number of revolutions dwindles, but the power keeps up pretty well, because each explosion does more work than at the higher motor speed, and as a result it does not become necessary to change gear. With a view to obtaining a maximum of power, it is more important that any small motor designed to produce power by increase of the motor speed would need to be constructed with all its organs of extremely robust dimensions. The cylinders would need thick walls, yet the cooling would have to be very energetic, and a large quantity of water would have to be carried. The radiator would need to be large and the lubrication system more effective than any now in use. With the reciprocating parts heavy enough for their work and most carefully balanced to offset the effect, as far as possible, of their increased weight, it seems very unlikely that the proposed system of forced admission could be materialized at as low a weight per horsepower as is attained by the methods now actually adopted in the most advanced practice; namely, by a long stroke which diminishes the rotary speed while increasing the piston speed and by multiple valves of large areas which assure a good filling of the cylinders even at high rotary speed.—*La Vie Automobile*, September 17.

Generating teeth from a rack-shaped cutter of the Sunderland type of gear shaper is the latest idea in shop equipment in England. It is claimed by the makers of this type of machine that the cost of doing the work is lower than when the hobbing machine is used, and that it is more accurate.

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL CLIMBS, ETC.

Oct. 18	New York City, Madison Square Garden, Electric Car Day at the Electric Show.
Dec. 1	Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Dec. 31-Jan. 7, '11.	New York City, Grand Central Palace, Eleventh Annual International Automobile Show.
Jan 7-14, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Manufacturers.
Jan. 15-21, 1911	Detroit, Wayne Gardens, Detroit Automobile Dealers' Association.
Jan. 16-21, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4,'11.	Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories, Exclusively.
Feb. 6-Feb. 11,'11.	Chicago Coliseum, Tenth National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.
Mch. 4-11, 1911	Boston, Mechanics' Building, Ninth Annual Show, Licensed Automobile Dealers' Association.

Races, Hill-Climbs, Etc.

Oct. 14-18	Washington, D. C., Start of Washington Post Reliability Run to Richmond, Va.
Oct. 15-16	Philadelphia, Roadability Run, Automobile Club of Philadelphia.
Oct. 15-18	Chicago, Ill., Chicago Motor Club's 1,000-Mile Reliability Run.
Oct. 22-30	Belmont Park, New York, International Aviation Tournament and Show of Licensed Automobile Dealers of New York City.
Oct. 27-29	Dallas, Tex., Track Meet.
Oct. 28-29	New York City, New York "American's" Motor Truck Contest.
Oct	Exhibition Auto vs. Aeroplane, Dutchess County Fair, Poughkeepsie, N. Y.
Nov. 3-5	Atlanta, Ga., Speedway Meet, Atlanta A. A.
Nov. 5-6	New Orleans, La., Track Meet.
Nov. 10-12-13	San Antonio, Tex., Track Meet.
Nov. 11-12	Savannah, Ga., Grand Prix, Automobile Club of America.
Nov. 24	Redlands, Cal., Hill Climb.
Nov. 24	Savannah, Ga., Road Race, Savannah Automobile Club.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

THE broad field of the automobile includes three generic types of machines, i. e., the steamer, then the electric, and finally the gasoline car, named in the order of their commercial introduction, with some mixing of dates, which might afford ground for controversy without affecting the points that are to be made here.

* * *

GRANTING that the steamer has survived, the fact remains that it is extremely well represented by a very limited number of designs, and it has been admitted by men who have made a study of the situation that activity in this field has been suppressed largely on account of the concentration of basic patents, thus prohibiting those who might like to build steamers from making a stable investment.

* * *

WHETHER or not it is a good idea to suppress broad activity by enforcing patent rights is too much of a subject to be handled with brevity, but the fact remains that the internal combustion motor, using gasoline at $32 per ton for fuel, has almost monopolized the field, although it, too, is somewhat affected by the patent situation.

* * *

ELECTRIC vehicles occupy a unique position in the battle for automobile supremacy. If they have failed to make sufficient headway, it is because the problems involved are insurmountable to the average engineer, and the work to be done must be assigned to the hands that respond to the motive power of a sufficiently vigorous set of brains.

* * *

EVERY trolley car in America pays tribute to the qualities that reside in electric motors, and the electrical method of doing work is so thoroughly established in a thousand ways that to come to its defense would be a waste of ill-directed effort.

* * *

SINCE it is not feasible to attach a trolley pole to a vehicle that is not confined to tracks, the source of electric energy must reside in a battery. It is in this battery problem that the retarding factor has ever resided, but despite the shortcomings of batteries of past history the electric vehicle has survived and thrived.

* * *

WHEN a doctor refers to a man with "vulgar" health, the possessor thereof is regarded as capable of devouring raw clams without being discommoded, and it is this vulgar health that has been missing in batteries as they were utilized in connection with electric vehicle work.

* * *

THE hope of the new generation from the electric vehicle point of view lies in the future good performance of the nickel-iron battery. It is a great misfortune that its qualities are under the shadow of too much talk. The public ear seems to have been wide open and the rubbish that has been poured into it for four or five years has clogged it up.

* * *

THE time has arrived when the plain truth is the only medicine that will be of any value whatever, but this truth will have to emanate from unbiased and reliable sources. That there is a reservoir of truth it is believed. The sooner it is permitted to flow through an unpolluted conduit, and its pure stream is focused upon the debris that litters up the public ear, the better it will be for all concerned.

* * *

CONVINCING evidence abounds at every hand which clinches the contention as previously made to the effect that despised stock cars are showing superiority over special racing machines, and the most substantial affirmation comes in the report of the Fairmount Park automobile race. A perusal of the tabulation of the score card, as printed elsewhere, shows that it was a stock car victory, and that foreign racing machines made a very poor showing.

* * *

THE time was when only specially made models were worth entering a race, and one of the strange things about these special models lies in the fact that very few of them ever finished. Those who abhor racing, and throw their weight against utilizing the automobile for such purposes, will scarcely need worry about it; as the situation presents itself now, there are so many stock cars crowding in at the finish that it lifts the whole performance out of the racing category. The life of racing depends upon a hard contest for the winner, the placing of two or three cars at the most, and a pack of wrecks.

Toronto, Oct. 4/10.

Gentlemen, Please discontinue my subscription, as I now have a car, , which is absolutely satisfactory in every way & I consider it wiser not to read anything at all about other cars. Yours truly,

C.H. Fleming

LAPSE OF 10 YEARS

"Road 12.47—"

BY MARIUS C. KRARUP—THE DEWEY INDEX SYSTEM APPLIED TO ROADS, MAPS AND GUIDE BOOKS—A BOON FOR TRAVELERS AND TOURISTS—A BOOST FOR A NATIONAL ROAD SYSTEM

JUST because the United States is not yet a finished country, but one whose institutions are largely open framework to be filled out as modern progress shall dictate from time to time, the opportunities for improving here upon suggestions received from the more systematic but less elastic governmental supervision of public affairs which prevails in Europe are practically without limit. In matters of road building and road improvement American conditions have presented special difficulties, due to the predominating importance of railroads, to the relatively low prices for land, to the relatively thin population, to the scarcity of accumulated capital, as compared with the large number of undeveloped enterprises begging for investment, to the high cost of road construction, to the absence of military necessities and to a certain stiff-mindedness, which is essentially sound and goes with the institution of self-rule for communities, but which, on the other hand, delays and impedes all united effort from which direct economical reward is not self-evidently to be the result. Under these circumstances the American road system has probably been developed as rapidly as reasonably could have been expected and, when everything is said, perhaps more rapidly than that of any other country, although a much earlier start has given other countries the lead for the present. Comparison on more nearly even terms could be established with reference to the modern problems of rendering roads dustless and with regard to the suitability of the means adopted in the various countries for reducing the cost and improving the quality of the roads beyond the traditional standards for judging quality, in which respect America has a free hand and wider scope than Europe and ought to be leading.

The ultimate purpose of roads is, of course, to afford the best possible facilities for the transportation of persons and goods from one place to another, and to have these facilities accord with the tastes and preferences of the population, as well as with all economical and financial requirements. All other advantages of a perfect road system may be summed up as a general and very effective tendency toward raising the standard of civilization by advancing co-operation between town and country in business and pleasures, but these, however important, are only incidental.

In order that people may be enabled to travel with facility and dispatch from one place to another over a network of roads, by day or by night, not only roads of good quality are required, but it is necessary that the traveler shall be able to pick his way without tedious inquiries, often resulting in unreliable answers, and without risk of straying from the good and the short road to the bad and the devious one. Signposts and guide books and maps serve this purpose in a most cumbersome manner, as all tourists know, mainly because no rational system has been devised for distinguishing the road which leads to A from the road which leads to B. Signposts as a rule indicate only the nearest town, and the traveler whose destination is farther on must consult his memory, his map or his book to make sure whether that town is on his best route or not. The two roads look alike in the landscape or, if they look different, the meaning of the difference is not clear. Means for identifying the road in the landscape with the lines which mark the road on the map have been developed ingeniously by private enterprise, but depend on scattered landmarks, far between, on the cyclometer reading and on a nomenclature for the roads which is not always recognized locally, neither in word of mouth or by inscriptions on signposts. The name of a road, if one exists, is necessarily either lengthy or indefinite. To paint it on signposts is expensive, and it is not done.

These troubles for the traveler exist in greater or lesser degree in all countries. They have been accentuated through the universal use of automobiles. They interfere seriously with that freedom of movement which is one of the chief charms of automobile touring, and by that much they lessen the value of automobiles as well as of roads. In the countries of Europe, however, and particularly in France, where the care of roads and bridges is in the hands of the department of *Ponts et Chaussées,* the roads are listed in the archives of the administration and on the maps used for its officials, by number. The national pike is marked N. 32, or whatever the number be. The departmental chaussée is marked D, followed by the numeral distinguishing it from other departmental chaussées, all of which are in the same class. The road of *"grande communication,"* or highway, is marked such as G. C. 67 or G. C. 289, and even the roads of lesser degree and excellence are denoted by the initials of their class and a distinguishing number. A prominent tire manufacturer in France, who is naturally much interested in fostering touring, discovered that it would be a great help to have the official designation by class and number extended to the maps in the hands of the public, and he had such maps printed. Their usefulness was much reduced, however, because the numbers were not to be found on the roads themselves. He proposed that signposts and kilometer stones should be marked with the numbers, too, but nothing was done. Others have taken up his cry, but the hide of French administration is thick. The local authorities are averse to expense, even one which would seem petty in America. The speed of automobiles on French roads is so high that rural communities look with scant favor upon anything which might make it higher or the number of automobiles greater.

Not France but the United States is the country which needs the numbering system most, and, starting with a clean slate, the United States has an opportunity for developing the numbering system in a modern manner and rendering it much more thorough and useful than it could be made on the basis of the existing French official classification. The Dewey system for card indexing and for finding one's literary way among the labyrinthine shelves of a big library offers a solution whose manifold advantages for the traveler and eventual influence for the orderly development of an economical road system can scarcely be fully perceived at the first glance. As is well known, the Dewey system gets definition and boundless elasticity alike by the simple use of a period and decimals. Large and fundamental divisions of a subject are classified by the numeral to the left of the period and all subdivisions by the decimals. A designation such as 123.147 indicates the seventh subdivision of the fourth classification under the first distinct branch of subject No. 123. It may just as well be made to indicate the seventh country road branching from the fourth county road running from the first State road starting from trunk highway No. 123. Evidently a road—if it is not in the immediate vicinity of some highly specialized destination, such as one of the minor streets of a village or a country place reached by a number of private lanes—may practically always be indicated as briefly as, for example, 26.94. The finesses of the Dewey system by which more than nine subdivisions of the next higher classification may be included, are not required for road classification. The signposts need not give room for more than a few numerals, usually not more than three or four. The expense of painting these brief indications on a post, with or without crossboard, is slight. The posts need not be higher than three feet above the ground. Indeed, to facilitate night driving, the low location of the numbers is preferable, as in that case the light from the lamps of an automobile may be turned upon them without special difficulty. But at all events an arrangement by which a small lamp attached within reach of the driver may be turned so as to throw a cone of light in any desired direction, high or low and to the side, would be a small price to pay for the convenience of knowing the road with certainty in the dark. To insure absolute definition, it might be desirable to paint a horizontal line on that side of the number which points to the beginning of the road, and on a signpost at one side of the road this line would precede the number while on a signpost at the opposite side it would follow the number. Rapidity in deciphering a sign while driving would be served by painting the leading number larger than the decimals. A sign, then, would look as follows:

—12.^{47} or, on the other side of the road, **12.**^{47}**—**

A traveler having directions to follow trunk road 12, State road 12.4 and county road 12.47, would not need to trouble himself about crossroads, as he would know that any crossroad, starting from a different trunk road would have a different initial numeral or, if by some rare chance of devious ramifications it came back across the trunk road to the system of which it belonged, it would be denoted by more than one or two decimals. On the other hand, if his directions told him to follow 12, then 13.5 and finally 14.7, he would know that 13.5 was a road crossing and not branching from 12, and similarly that 14.7 was a crossroad with relation to 13.5.

Just as French officials know by the prefix N or D or G.C. of what degree and quality a road should normally be, the American traveler would have a strong indication of the quality by the number of decimals, provided the whole numbering system were laid out with some reference to the importance of the different roads.

At this point the question arises, how the authorities may be made to co-operate in instituting a numbering system and instituting it in the best possible manner. The first requirement for obtaining a suitable foundation would seem to be the selection of trunk roads. In practice they do not exist, but there exists a network of roads varying in quality, by which a traveler can get from New York to Buffalo or from New Orleans to Chicago by following a stretch of good road here and a stretch of bad road there. The long-distance haul is of no importance; hence a straight line connection between distant points is less to be aimed for than a trunk road following the lines where a considerable established traffic justifies the expense of road improvement. The trunk roads should, then, follow the lines of established traffic as closely as possible. Preparatory work is wanted for ascertaining beyond dispute the amount of traffic over various routes throughout the United States. The trunk roads should connect these routes on the plan of securing the largest possible traffic per mile. By counting the traffic on predetermined (but not necessarily advertised) days and simultaneously at a large number of points, the mileage as well as the number of the travelers could be approximately fixed, and the short-distance, inter-village traffic would not count for more than it should. Apparently a special road commission, specially authorized by Congress, would be required for uniting all efforts and laying out on the map the system of trunk lines from which a numbering system would have to take its beginning. The drawing of a bill specifying the composition, the authority and the work of such a "Special Federal Commission for Preparing a System of Road Numbering" would seem to be the first step to be taken. And at this point the suggestion may be left for the present.

Many 1911 Models at National Vehicle Show

CHICAGO, Oct. 11—The motor car division of the National Vehicle Show which opened in the Chicago Coliseum yesterday formed no inconsiderable part of that affair. Twenty-four different makes of cars are represented by sixty-five machines. The Martin Carriage Works of York, Pa., has on view three commercial motors in addition to its regular line. There are two huge Sternberg trucks, the Kisselkar Leviathan, the Hupmobile, Cutting and Owosso lines.

In the Auditorium proper, there are eighteen different makes, including the Warren-Detroit, the International Harvester, Studebaker, E-M-F and Flanders, the Powercar and the Ames, besides five Imperials, two Schachts, three Patersons, three Lamberts, four Whitings, one Staver, three Readings, six Michigans, two Zimmermans and four Abbott-Detroits.

International Show Dates Announced

Formal announcement of the "Eleventh International Automobile Show" to take place in Grand Central Palace, New York, from December 31, 1910, to January 7, 1911, has been made by the American Motor Car Manufacturers' Exhibit Association.

The association has announced that it has been working on the details of the show since last January and declares that so far the prospects for a successful show are excellent.

Big Dash to Phoenix from Los Angeles

Eleven entries are of record in the run that is to take place from Los Angeles to Phoenix, Ariz. The run will start from the Hollenbeck hotel on the night of November 5. Entries will close October 21. A four-cylinder Knox car, driven by Joe Nickrent, accompanied by his father and brother, left Los Angeles last Thursday to make the preliminary dash. This is to be the big event of the year in Southern California. The entries now include Maxwell, Kissel-Kar, Apperson, Ohio, Pope-Hartford, Velie, Ford, Rambler, Franklin, Mercer and Knox cars.

Atlanta Meet Has 45 Entries to Date

ATLANTA, GA., Oct. 11—Work is nearly completed on the surface of the Atlanta track and it is practically ready for the practice work for the Fall Speedway meet, set for November 3, 4 and 5. A considerable strip of the back stretch has been torn up and resurfaced, a couple of thousand small holes in the surface have been filled in and the bumps have been thoroughly tamped down. Entries to the number of 45 have been received.

Electric Vehicle Association to Meet

The First Annual Convention of the Electric Vehicle Association of America takes place at the concert hall of Madison Square Garden October 18.

The meeting will be of interest to manufacturers of electric vehicles, storage batteries and their attendant appliances; to those representing central stations as indicating a field in which exist large possibilities of future growth; to those considering the use of electric vehicles, and especially to those who are engaged in the practical work of operating and maintaining transportation equipment of this type.

An interesting and practical program has been arranged.

Selden Cases Set for November 9th

A motion was heard Monday by the U. S. Circuit Court of Appeals for the Second Circuit, to give preference to the hearing of the appeal in the suits under Selden automobile patent against the Ford Motor Company and Panhard Company and the other test suits. The court has set these cases, which are on appeal from the decision of Judge Hough sustaining the Selden patent, at the head of the Court of Appeals' calendar for hearing November 9.

In the case of injunction under Selden patent against John Wanamaker, a motion was brought by the defendants to suspend. This was opposed and Judge Hough denied the application for suspension, so that the injunction continues in force.

Recent Events Among Aviators

NO CHICAGO-NEW YORK CONTEST—ALTITUDE RECORDS—NEW PRIZE FOR BELMONT PARK MEET

THE number of fliers competing for the $25,000 prize offered by New York and Chicago papers for a flight between these two cities was finally reduced to one before the start was made. The two others made a perfunctory hop over the fence of the Hawthorne racetrack and retired, this action being in accordance with an agreement made between the fliers themselves and ratified by the newspapers in question. Among the three entrants, Eugene B. Ely was the one selected to fly, while J. A. D. McCurdy and C. F. Willard retired in his favor and offered to do all in their power to help Ely finish the flight, by placing spare motors and parts at his disposal when needed. They are all identified with the Curtiss type of biplane. In the views offered in explanation of the change of plans on the part of the aviators, who may be considered as a Curtiss team, it is stated that none of the special aviation motors at the disposal of the fliers could be expected to endure the strain of being operated near its full capacity for seven days in succession, even only for a limited number of hours each day, and that consequently any contestant, in order to have reasonable hope of reaching New York, must have several motors at his disposal, a condition which, for lack of motors, could only be met by two of the contestants traveling by rail with their motors and having them ready for the assistance of the third contestant when needed. Ely started from Chicago Sunday instead of Saturday, though the weather on Saturday was favorable. He had repeated troubles with the carbureter and by Monday night had reached no farther than East Chicago. After a repetition of his former troubles on Tuesday he finally announced his abandonment of the enterprise.

William R. Hearst, the owner of the Hearst chain of newspapers, has offered a prize of $50,000 for the aviator who first accomplishes a flight from Boston or New York to Los Angeles or San Francisco, going by way of Chicago and finishing the flight within thirty days after starting and before the expiration of one year after October 8, 1910.

Archibald Hoxsey in a Wright biplane flew on October 8 from Springfield, Ill., to the grounds of the St. Louis Country Club, at St. Louis, making a detour to Staunton, Ill., the aviator's home town, and covering in all a distance of 104 miles in one continuous flight. He started at 11:56 a. m. and landed at 3:35 p. m. Hoxsey's arrival was the signal for the opening of the St. Louis aviation meet, which will be continued until October 16, and includes an international balloon tournament. Five Wright biplanes are represented at the meet, and Alfred Leblanc will fly in his Blériot monoplane equipped with a 100-horsepower Gnome engine.

A new altitude record, beating that made by Chavez shortly before his fatal flight over the Alps, was made by Wynmaelen, a Dutch aviator, at Mourmelon, France, on October 1. According to the dispatches Wynmaelen used a biplane and reached a height of 9,174 feet. Descending without power in 13 minutes he suffered none of the nausea which overtook Morane when the latter descended in less than 8 minutes from a height of about 7,800 feet. The previous altitude record with a biplane was made by Brookins at Atlantic City with a motor of about 28 horsepower.

Leon Morane, with his brother Robert as a passenger, attempted on October 5 to win the Michelin prize of $20,000 for a continuous flight from Paris to Puy-de-Dôme, a mountain 4800 feet high, near Clermont-Ferrand, but fell near Boissy and broke one leg. His brother was probably mortally injured. The machine was a Blériot. Morane held the record for altitude with a height of 8,471 feet, which was subsequently beaten by Chavez. In one of his descents from a great height Morane shut off the spark without shutting off the gas, and the cooling effect resulting from the continued aspiration of vapor was sufficient to congeal the lubricating oil, causing the piston to stick and preventing the restarting of the motor.

Whoever at the International Aviation Meet beginning at Belmont Park, L. I., on October 22, shall fly from the aviation field to Liberty statue in New York harbor, circle the same and return to the grandstand in one continuous flight and faster than any other will receive a prize of $10,000 offered by Thomas F. Ryan for any performance which his son, Allan F. Ryan, the general manager of the meet, and De Lancey Nicoll might agree upon as most suitable. René Barrier, E. Audemars and Roland Garros are new foreign entries. Barrier will take the place of Léon Morane, using the latter's 100-horsepower Blériot monoplane, which had been shipped before Morane was injured. Audemars flies a Nieuport monoplane and Garros an improved Demoiselle, the diminutive monoplane designed by Santos-Dumont. Charles K. Hamilton is practising at Hemstead Plains with his new 110-horsepower biplane, which is said to be largely of his own design, and much interest is awakened in the competition for speed and endurance between this flier and the French aviators, Leblanc and Barrier, who use 100-horsepower Gnome engines and Blériot monoplanes.

"T. R." added the air to his list of conquests last Tuesday.

First Open-Air Show for New York Motordom

Announcement has been made that the Licensed Automobile Dealers of New York will take part in an exhibit of cars at the International Aviation Tournament, which is to be held at Belmont Park, October 22 to 30. M. J. Budlong, president of the association, has secured the exclusive right for the members to show their cars at the meeting. The floor space in the betting ring and under the grandstand amounts to 40,000 square feet available for exhibition purposes.

The show will be the first outdoor affair ever undertaken by the New York dealers, and in connection with the aviation meet is expected to draw an attendance of not far from 500,000.

The meeting has been sanctioned by the A. L. A. M.

Many Cars at Illinois State Fair Show

SPRINGFIELD, ILL., Oct. 11—Automobile exhibits formed an important item at the Illinois State Fair, held in Springfield, September 30 to October 8, thirty makes being shown, among them the Midland, Winton Six, Halladay, Westcott, Overland, Davis, Staver-Chicago, Case, Zimmerman, Inter-State, Lexington, Auburn, Regal, Black Crow, Glide, Rambler, Jackson, Cadillac, Studebaker-Garford, E-M-F, Flanders, Mitchell, Studebaker, Chalmers-Detroit, Stoddard-Dayton, Cutting and Velie.

Candidates Buy Lozier Automobiles

Lozier touring cars recently have been purchased by John A. Dix, Thomas F. Conway and Jay Cothron. All three are ardent motorists and forceful advocates of good roads. Messrs. Dix and Conway are leading candidates for high State offices.

Oldfield Falls Under Official Ban

Barney Oldfield was indefinitely suspended by the Contest Board, Tuesday, for insubordination and disrespect in advertising an unauthorized race.

The new Waters road ready for use

Near Ferguson Avenue, as level as a floor

Savannah Gets Grand Prix

BIG RACE TRANSFERRED FROM LONG ISLAND TO SOUTHERN COURSE AND WILL BE RUN NOVEMBER 12—CLASS RACE TO PRECEDE GREAT EVENT

SAVANNAH, GA., will be the scene of the second Grand Prize race for the emblem of the Automobile Club of America, sanction for the event having been recommended for that city at a meeting of the Contest Board of the club on Monday afternoon. The race will take place November 12 and will be preceded by a contest under piston displacement classes, November 11. While the exact limits of this race have not yet been defined, it is said that as many as five divisions under class B or C will be provided, but the probability is that the racers in this section will be limited to divisions 2 and 3 of Class C.

The conditions of entry to the big race will remain the same, that is, unlimited as to size and power, save for width, which must be less than 68.89 inches.

When the Motor Cups Holding Company abandoned the race, which was scheduled for next Saturday on the Long Island Parkway, several other cities applied for permission to stage the race. Among these were Savannah, Philadelphia, Los Angeles, Atlanta and Indianapolis. The city of Savannah, however, went after the race with a vim and dispatched a delegation to New York last Saturday consisting of Mayor George W. Tiedeman, Harvey Granger, O. T. Bacon and A. B. Moore, county commissioners, and Arthur Solomon, secretary of the Savannah Automobile Club, as well as several others.

These gentlemen conferred with the Contest Board of the club from Sunday afternoon until Monday evening, and at the conclusion of the deliberations the Contest Board announced that it would recommend a sanction for Savannah.

One of the considerations in granting the recommendation was the assurance carried to the Contest Board by the delegation that the Governor of Georgia would order out at least a regiment of State troops to police the Savannah course during both races.

The course, as promised by the delegation, will be 18 miles long, with only seven turns. The route over which the 1908 race was run was 25 miles with 19 turns. The improvements in the roads contemplate the following changes: The old White Bluff road will be eliminated. The starting point will be on Waters Road, which was used in the light car race two years ago. Much work has been done to perfect this stretch and it is in excellent shape. The course generally is composed of hard-packed cement gravel, the turns are banked rather high and all but two of them may be taken at speed. Leaving the Waters road, the course is laid out over the Intermediate road, Whitefield avenue, Montgomery road, Ferguson avenue, Norwood avenue, La Roche avenue, Thunderbolt road, Dale avenue to the Waters road. This route eliminates the Isle of Hope, as Norwood avenue cuts through in a direct line to Ferguson avenue and gives a straightaway of more than eight miles. The widest stretches of the course are about 50 feet and the narrowest 20 feet, generally level and as smooth as a billiard table.

Showing one of banked turns, ready for use—the speed possibilities are great

Draw Space for Chicago Show

MAKERS AND ACCESSORY MEN SECURE ALLOTMENTS AND ALMOST ALL ROOM IS ASSIGNED FAR IN ADVANCE

ABOUT seventy-five manufacturers attended the drawing for space at the Chicago show which took place at the office of the National Association of Automobile Manufacturers, Inc., last week. All the space for pleasure cars was assigned.

Applications from makers of commercial vehicles for such space as remains in the Coliseum and in the armory will be received up to October 31.

Following is a list of makers to whom space was allotted:

PLEASURE VEHICLE SECTION

Coliseum:

1910 Edison Storage Battery

(Continued from page 612)

This monstrous abuse is at the bottom of all the failures that have been made heretofore, and it is yet to be said that the batteries used in vehicle work are made as light as possible, nor must it be forgotten that the lighter they are the more frail they will be. In central station work the questions of weight are handled on a basis of the advantage afforded from the investment point of view, and cognizance is taken of the fact that it pays to add to the weight of the battery up to the limit where the increased life ceases to pay the current rate of interest on the investment. In vehicle work, however, all such considerations are cast adrift; the sole requirement is to so design the battery that it will come within the allowable weight, afford the requisite energy for the desired radius of travel, and last long enough to make it worth while, taking into account the absence of electrochemical skill on the part of the owner of the car and the wish on his part to go somewhere and come back again.

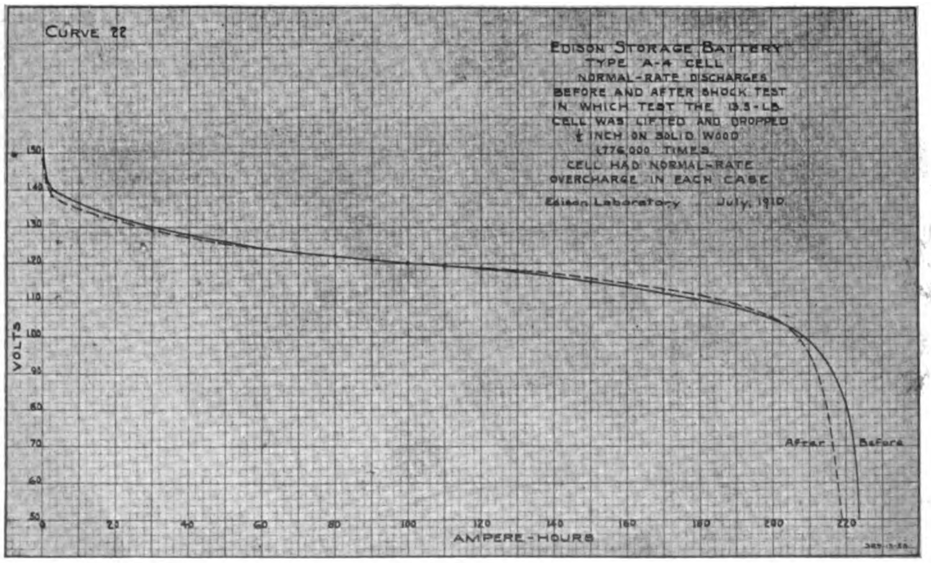

Fig. 3—Chart showing normal rate of discharge of a Type A-4 cell before and after shock test

The Edison vehicle battery, as shown in Fig. 1, is composed of a plurality of cells, made up of positive and negative elements in a steel can, the latter being sealed, and as the illustration shows, six of these cells of battery are joined together and assembled in a wooden crate. Three crates of cells are shown, but there may be any number, depending upon the potential difference required in charging, and the design of the charging equipment. The general appearance of the cells composing the battery is shown in Fig. 2, indicating five sizes, as used in general service, vehicle transportation, vehicle lighting and ignition work. These cells of battery are known at the Edison plant as type "A" or "B." and are marked A-4, if there are four positive elements, A-6 if there are six positive elements, and A-8 if there are eight

Detroit Automobile News

E-M-F CUT, NEW FOUR-PASSENGER MODEL HUPP, AND A DOZEN OTHER SUBJECTS OF LIVE INTEREST TO MOTORDOM GENERALLY ARE CHRONICLED

DETROIT, Oct. 10—Something of a stir was created last week by the announcement of the E-M-F Co. that it had decided to reduce the price of the E-M-F "Thirty" from $1,250 to $1,000, and the Flanders "Twenty" from $750 to $700. President Flanders gave as the reason for this action the fact that manufacturing facilities had increased to an extent where it was possible to make cars at this figure without sacrificing quality or workmanship and still have a reasonable profit left. It is strongly intimated, however, that an inkling that some other manufacturers were contemplating a cut in price was responsible for this sudden action on the part of the E-M-F Co. The cut was announced at a meeting of E-M-F branch managers.

Robert K. Davis, manager of the United Motor Detroit Co., Michigan distributor of the Maxwell-Briscoe and Columbia cars, entertained the company's Michigan agents at luncheon in the Griswold House, Saturday, when the policy for 1911 was outlined. Mr. Davis announced positively that there would be no cut in Maxwell and Columbia prices.

Another low-priced automobile claiming Detroit as its home will shortly make its appearance, announcement being made that before Nov. 1 the Hupp Motor Car Co. will place on the market a four-passenger car selling for $900. The car will have the same 20-horsepower motor that has been used in the Hupmobile, but will have a wheelbase of 110 inches and sell for $900. At the same time the Hupp Company announces that it will guarantee all its cars for life.

The Wolverine Motor Club, organized some months ago, and already counted among the most energetic of local bodies, is making a vigorous campaign with a view to securing 3,000 members by Jan. 1. A club house is also in prospect. The club has proffered the services of its members to Police Commissioner Croul in the campaign against reckless driving.

The Reo Motor Truck Co., of Lansing, has filed $1,000,000 articles of incorporation with the Secretary of State. R. E. Olds, James H. Thompson and J. Edward Roe, of Lansing, are named as stockholders.

The Motor Manufacturing Co., of Muskegon, has increased its capital stock from $100,000 to $150,000.

The Demot car plant will shortly be put in operation again, the receiver of the company having been ordered by the court to take such a course. The receiver has accordingly contracted with the Ross & Young Co. to do the machine work and assembling.

The Detroit Metal Founding Co. has been incorporated with a capital stock of $25,000.

The Oliver Motor Car Co. has just moved into its recently acquired plant in the western part of the city, and is installing mechanical equipment which will give it one of the best commercial car plants in the city.

Much of the uneasiness which prevailed in motor car circles has been removed by official announcement of the closing of the $15,000,000 loan by the General Motors Co. The news was particularly welcome in Flint, where it is taken to mean a speedy resumption of activities at the Buick and associated plants on a wide scale. Other General Motors plants throughout the State also expect to be favorably affected by the settlement.

---

positive elements, or B-2 if there are two positive elements, and B-4 if there are four positive elements. The B-4 size is rated at 90 ampere hours, and besides offering a wide opportunity in ignition work, is available for the electric lighting of gasoline automobiles. The B-2 size is rather too small (45 ampere hours) for electric lighting and is confined to ignition work. The "A" series are designed specifically for electric vehicle service and street car work.

Of the remaining important general considerations not heretofore discussed, one takes into account the effect of shock and jar upon the battery and vehicle service, and in the Edison Laboratory a machine was devised by means of which a cell of battery undergoing a shock test is lifted and dropped (falling under the force of gravity) once every second, continuously, and this process has been going on for a couple of years, so that the effect of shock and jar upon the Edison battery was determined in this way. Fig. 3 is a chart so contrived as to show the normal rate of discharge of a type A-4 cell, before and after shock test, in which the cell weighing 13.5 pounds was lifted and dropped ½ inch on solid wood 1,776,000 times. The solid line in the curve represents the discharge before the shock test, and the dotted line is plotted from the discharge after the shock test.

The remaining general consideration, not considering electrochemical phenomena, involves the effect of short-circuiting the battery. Fig. 4 shows the apparatus used in the short-circuiting test, in which A-4 is the cell of battery, S1 is the breakdown switch, C1 and C2 are large diameter electrical conductors of very low resistance, used in making the connections between the battery terminals and the terminals of the switch. A1 is the ampere meter of the Weston type, with a shunt S11 used in conjunction with the ampere meter in taking the readings in amperes during the short-circuiting period.

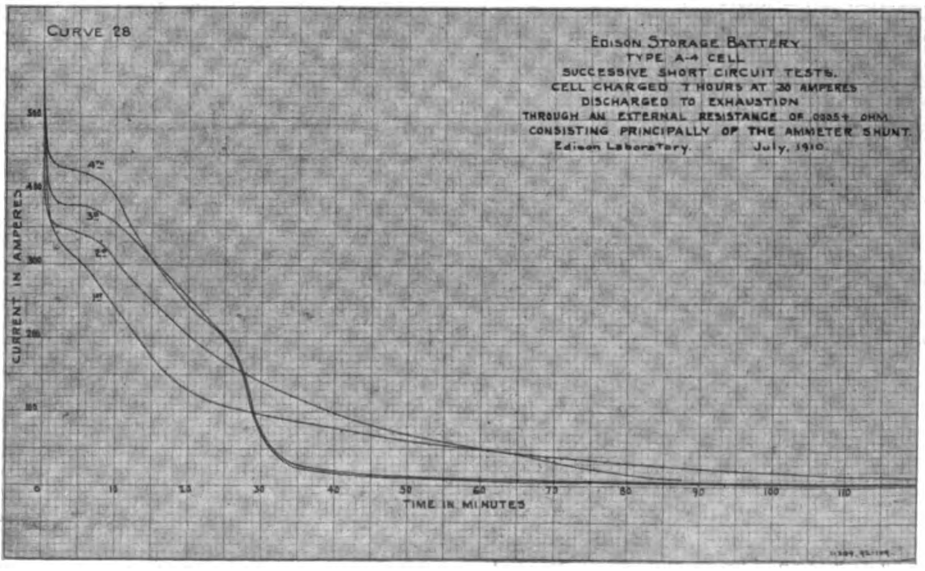

Fig. 5—Chart showing the discharge of a Type A-4 cell under short-circuiting conditions

Prominent Automobile Accessories

CONFORMS WITH THE LAW

A new lamp that fully complies with the law that compels cars in some States to have rear number plates illuminated at night has been placed on the market by John L. Parker Company, 62 Jackson street, Worcester, Mass.

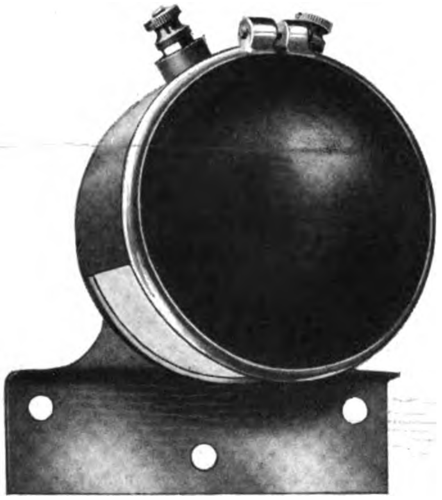

Fig. 1—A rear lamp that conforms with law

It is a combination lamp and number-plate holder and its appearance is very neat and compact. The large red lens is a semaphore pattern ruby and shows a clear light for a great distance. The bottom of the lamp is fitted with a clear white glass set in such a position that the light is thrown upon the number. The current is supplied from a six-volt storage battery to a two-candlepower lamp (Fig. 1).

LIGHT WHERE YOU WANT IT

To wash a car properly—and in the majority of garages it is necessary to carry this operation out at night—a good light is required. The ordinary ceiling or drop lights are inadequate as there is more dirt under the car than on the top surface. A handy portable wash rack light is marketed by The Brown Company, of Syracuse, N. Y., and when this is in use all other lights can be extinguished. It is easily portable and consists of a four-footed cast-iron base with slats and solid quadrant for holding small pieces of sponges, chamois, soap, etc. Extending upward from the base is a 3-foot riser. Attached to this and held at any height by a thumbscrew is a twin socket and 12-inch reflector. With the outfit is an 8-foot covered wire extension and socket wired for immediate use (Fig. 2).

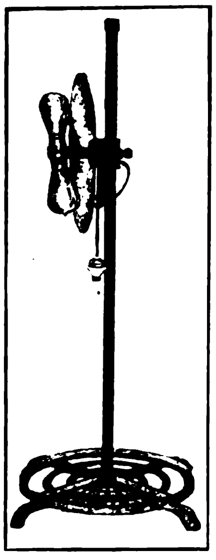

Fig. 2—Can be carried around the garage

SPARK PLUG SWITCH

An accessory that will save the autoist much time and trouble is manufactured by the H. S. M. Auto Switch Company, of 1118 Betz Building, Philadelphia, Pa. It consists of a cut-out switch to be attached to the spark plugs. In the endeavor to locate which cylinder is missing fire under ordinary conditions one has to use some tool, as a screwdriver, which, to say the least, is primitive, and unless properly insulated will result in a shock. By attaching the H. S. M. auto switch to the plug at one end and the high-tension at the other it is possible to ascertain in a minute where the trouble lays, and if the handle is held in the position indicated in Fig. 3 in the majority of cases oil or carbon will be burnt away without taking the plug out, owing to the spark being intensified crossing the gap made by the switch. It also obviates dropping plug terminals in the pan as there is no necessity to undo the terminal completely to remove the switch. If the cause of the misfire is in the circuit and not the plug this can instantly be seen, as when the switch is raised no spark will jump to the plug.

THE KELLOGG FOUR-CYLINDER PUMP

The pump illustrated in Fig. 4 is manufactured by the Kellogg Manufacturing Company, of Rochester, N. Y., and can be used for pumping up the tires or used in connection with a distributor for cranking the motor. It consists of a four-cylinder motor built along the lines of a gas engine and the method of its attachment can be changed, when desired, to suit any particular car.

Fig. 3—Time-saving spark-plug switch

It is being fitted to all 1911 Peerless cars in the manner illustrated, driven direct from the secondary shaft of the gear box. This is operated by a lever at the side of the car. A hose which is connected to the pump is coiled under the front seat. To inflate a tire, merely couple this hose on to the tire, move the lever and start the engine. It can be fitted to any car and if room cannot be found to couple up to the gear box a belt transmission from the propeller shaft would answer equally well provided it was only required to pump the tires. The base is cast aluminum with a shaft running in bronze bearings. The lift is effected by a hardened-steel cam which runs to a bath of oil. The pump is 8 inches long, 7 inches high and 2 3-4 inches wide. Each cylinder pumps free air, and as one of the cylinders is always on the up stroke a steady flow of air is obtained at all times.

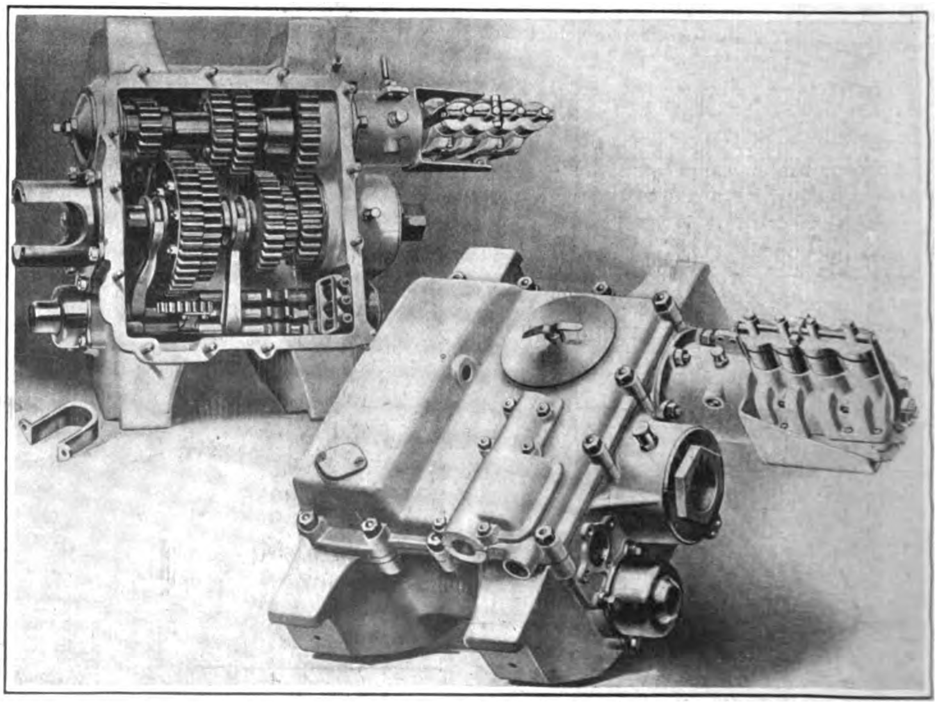

Fig. 4—A useful four-cylinder pump

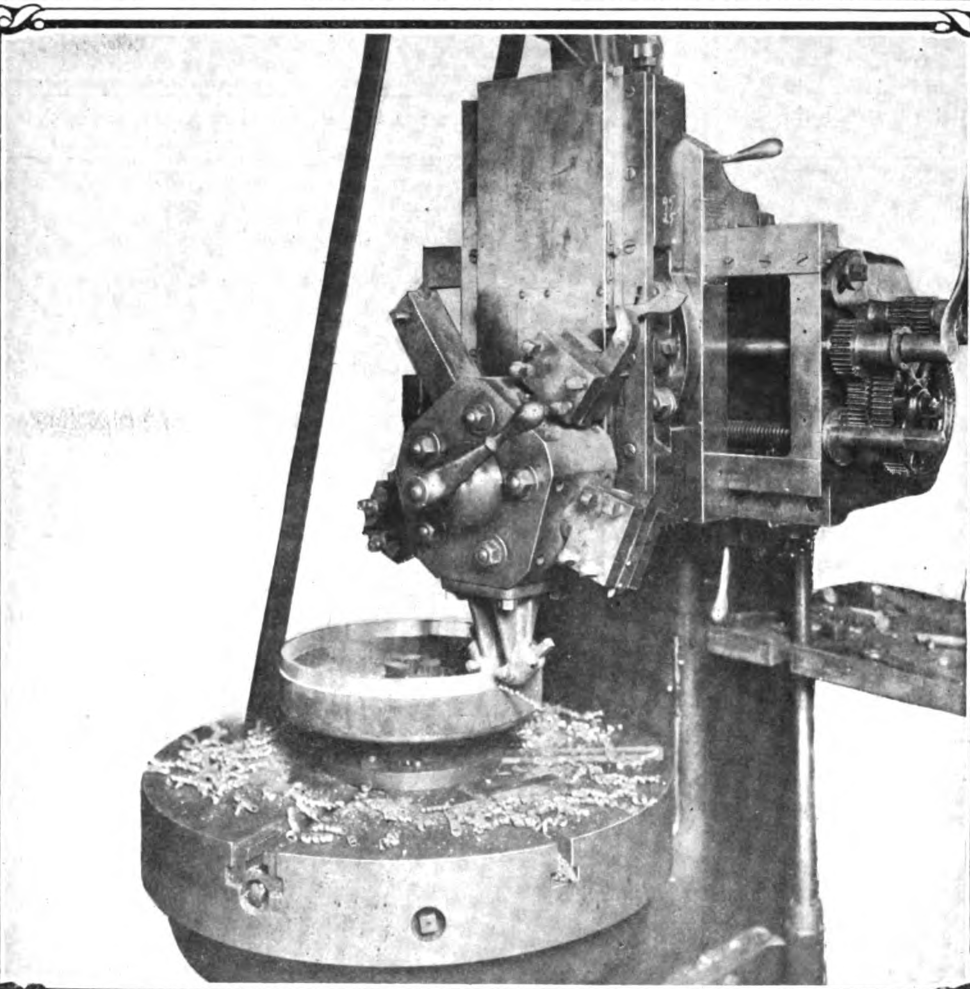
Vol. XXIII New York—Thursday, October 20, 1910—Chicago No. 16

The Automobile

Duplication Methods Supreme

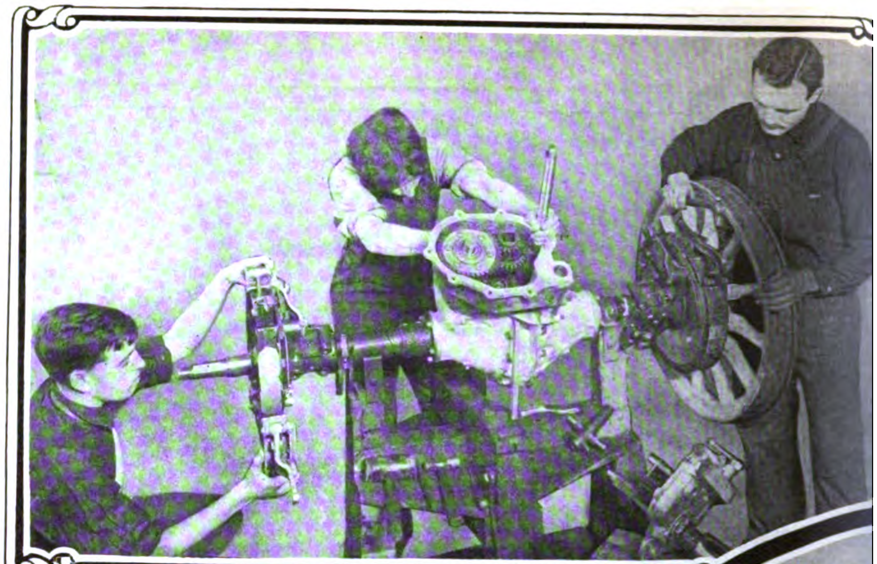


Vertical turret mill in the Premier plant on brakedrum work, simultaneously tooling inside and out

TEN YEARS of persistent effort on the part of American automobile builders, beginning in sharp competition with the foreign makers of cars, has resulted in the final supremacy of the methods involving the duplication of parts as practiced in American shops as against the methods demanding employment of a surfeit of labor, more or less skilled to be sure, but unguided by processing pictures and special machine tools of the character that compel uniformity. But it was not the primal idea of American makers to struggle against foreign competition; every skilled shop manager in this country is fully alive to the enormous handicap that anchors the foreign shops to an ancient precedent that puts a bar on quantity production, rendering it impossible for all such makers to consider, even for a moment, the enormous initial investment that must be made ere quantity production on a duplicating basis can be recognized as a reality.

During the formative period in American plants the output of automobiles suffered somewhat in comparison with importations of cars. Those who failed to see the dawn of the real automobile of the future were led to believe that foreign cars were better; that the materials were more suitable, the designs more scientific, and the workmanship on a higher plane. Purchasers of these automobiles found that they would not last forever, and when they went to the makers for repair parts they were astounded at the enormous cost thereof; but that was not all. It seemed strange to these purchasers that the parts as purchased, despite the beauty of their finish, would not go into place without being tinkered with, and they finally found out what every American builder predicted, *i.e.*, no two workmen, no matter how skilled they may be, will ever succeed in making two parts and have them on a duplicating basis.

It was soon discovered that the mere purchasing of a well-made automobile was not the whole story. The quality of a car will only be known to the buyer thereof after he finds out how much the maintenance cost will be. The price of an automobile is not determined by the amount of the initial payment; the real cost, in fact, is a matter of bookkeeping, and the final balance can only be struck when the life of the car is ended. The patrons of high-priced hand-made automobiles, while they could not have been purse-proud after they settled for the cars, looked down upon those who were far-sighted enough to go in for machine-made American automobiles for even a whole year after they took title to their rather nice-looking creations. The surprise came when repair accounts were put into contrast with each other. The less pretentious American automobiles naturally looked better after a year of service because it was possible to keep them in a state of good repair with the money that was still hiding in the purchaser's pocketbook after title was taken to the car. The cost



Assembling live rear axles at the Packard plant, employing three sets of men with military precision

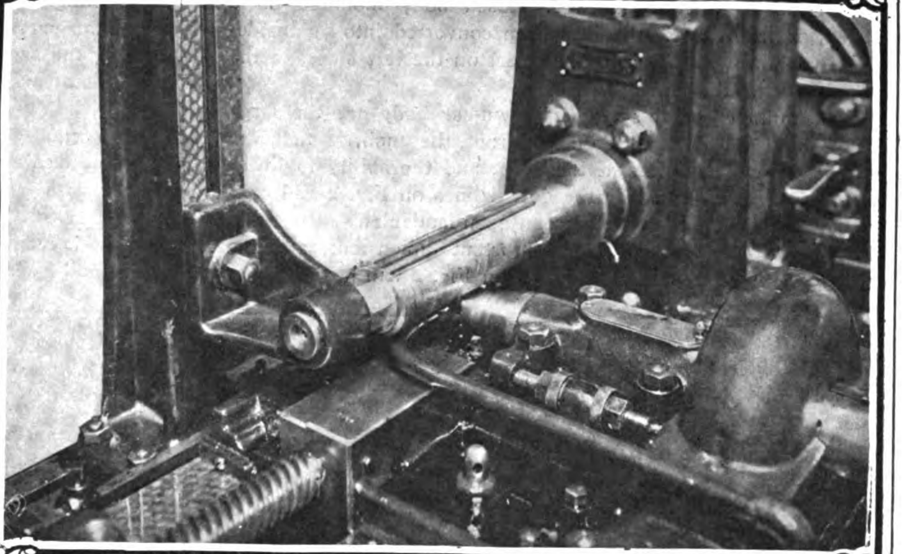
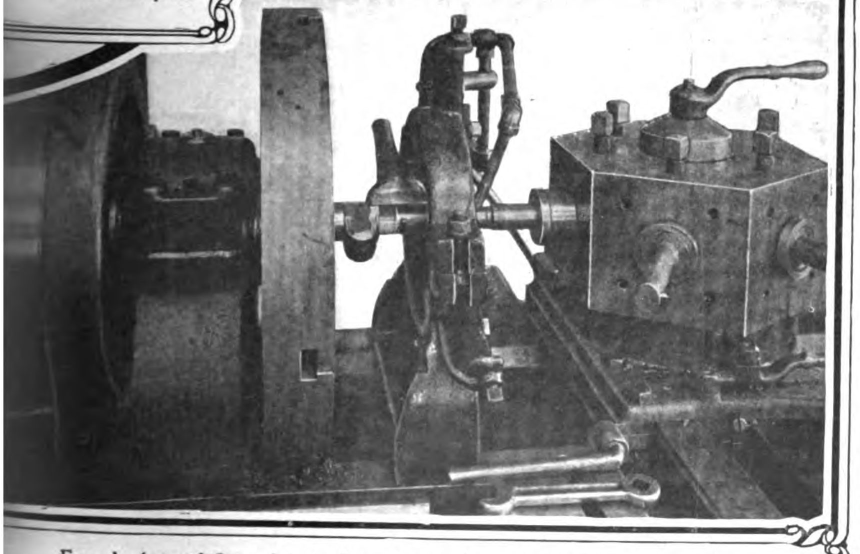
on at the Maxwell plant



Gould and Eberhardt gear cutter, cutting 17 blanks at one setting in the Brush plant



Example of turret lathe work in the Pierce-Arrow plant—finishing alloy steel knuckles

of maintenance was also within bounds, due to the uniform method of manufacture, but it will be a fallacy to overlook the great main consideration, *i.e.*, the cost of substituting repair for worn-out parts is nominal if the parts are made on a duplicating basis, whereas it is enormous if the parts are whittled out by hand and have to be reconstructed in the garage repair shop.

The history of the automobile, almost from its inception, due to the influence of the makes of cars that are not on a duplicating basis, is punctuated with intense dissatisfaction on account of the enormous garage expenses that have confronted automobilists. This problem has never been a serious one for the autoist who had the foresight to buy the kind of car that is made in a properly equipped plant, fitted out with machine tools of the character that cannot be used at all unless they produce parts on a duplicating basis.

In order to properly elucidate the point that is to be made here, illustrations of just a few of the leading shop processes are presented in which it will be observed that the workman is a mere spectator during the time that the operations are being performed by the machine tools. There is only one way by which a workman can be tolerated in a plant where parts are made on a duplicating basis, and that is, when he plays the part of a spectator only, excepting that he must be there in time to stop the machine when the work is done, replacing the same with new work, after which he again becomes a spectator, and is free to study algebra, if he like; lament over his past mis-deeds, figure on the world's series or build castles in Spain.

Of the unexplained difficulties involved in automobile work, experts have said very little to clear up the reasons why high-priced man-made cars wear out too soon. A broad statement of the underlying facts would, of course, have to take into account the expenditure of energy—in other words, losses—which much necessarily follow if the component parts are not made with precision and if the fits are poor. In the illustration of the live rear axle test at the Franklin plant the facilities are available for determining whether or not the live rear axles as made are on a duplicating basis, because since the parts come from the various departments *en masse,* they must be in replica of each other, or the assemblages will be faulty, and the brake test will show an excess of power taken and dissipated in the form of heat; in other words, the friction load will be too high. Without the motor testing methods at the Rambler plant it would be impossible to obtain a satisfactory result in the absence of duplicating methods in the shop because the electrical devices used in testing, together with the manograph check, would disclose the incongruities that are ever present when workmen alone are depended upon for accuracy. Other illustrations convey the impression of rigidity of the machine tools, as in the Pierce-Arrow illustration of alloy steel knuckle finishing. Other illustrations indicate multiple operations by means of which the quantity of work turned out is rendered sufficient to make it pay, as in the assembling of Packard axles, utilizing three sets of men simultaneously, they working with military precision, each gang independent of the other.

Inside-Drive Coupe Landaulet

GEORGE J. MERCER SHOWS IN DETAIL HOW THIS TYPE OF BODY MAY BE APPLIED TO A MITCHELL TAXICAB CHASSIS

IN the accompanying illustrations are shown in detail the construction of a four-passenger closed body mounted on a Mitchell taxicab chassis that has been converted into an inside-driven machine with the steering wheel on the left side and the change levers in the center.

The advantages of this type of town-car body are the large amount of light on the sides and the front, the unobstructed view from the rounded corners at the front and the ability to lower the rear part as indicated by the dotted lines on Fig. 2 and convert the body into the regulation semi-open landaulet.

Figs. 2, 3, 4 and 5 show the important dimensions, and the scale as presented along the base line on Fig. 2 will be a medium by which the other dimensions required can be quickly ascertained.

The seating is for four adults or three besides the operator. The cushion part of the operator's seat is made to tilt up as indicated by the arrow marks and the dotted lines on Fig. 2; this will permit of access from either side. The back of this seat is stationary, however, and the seat has the necessary stiffness and security to satisfy the driver.

This body can be made either with wood frame and metal panels or with wood panels, as the design is suitable for either form of construction. At the front the glass is divided and the upper half is made to swing outward to form a visor shield, and the door and back side glass frames are made to drop.

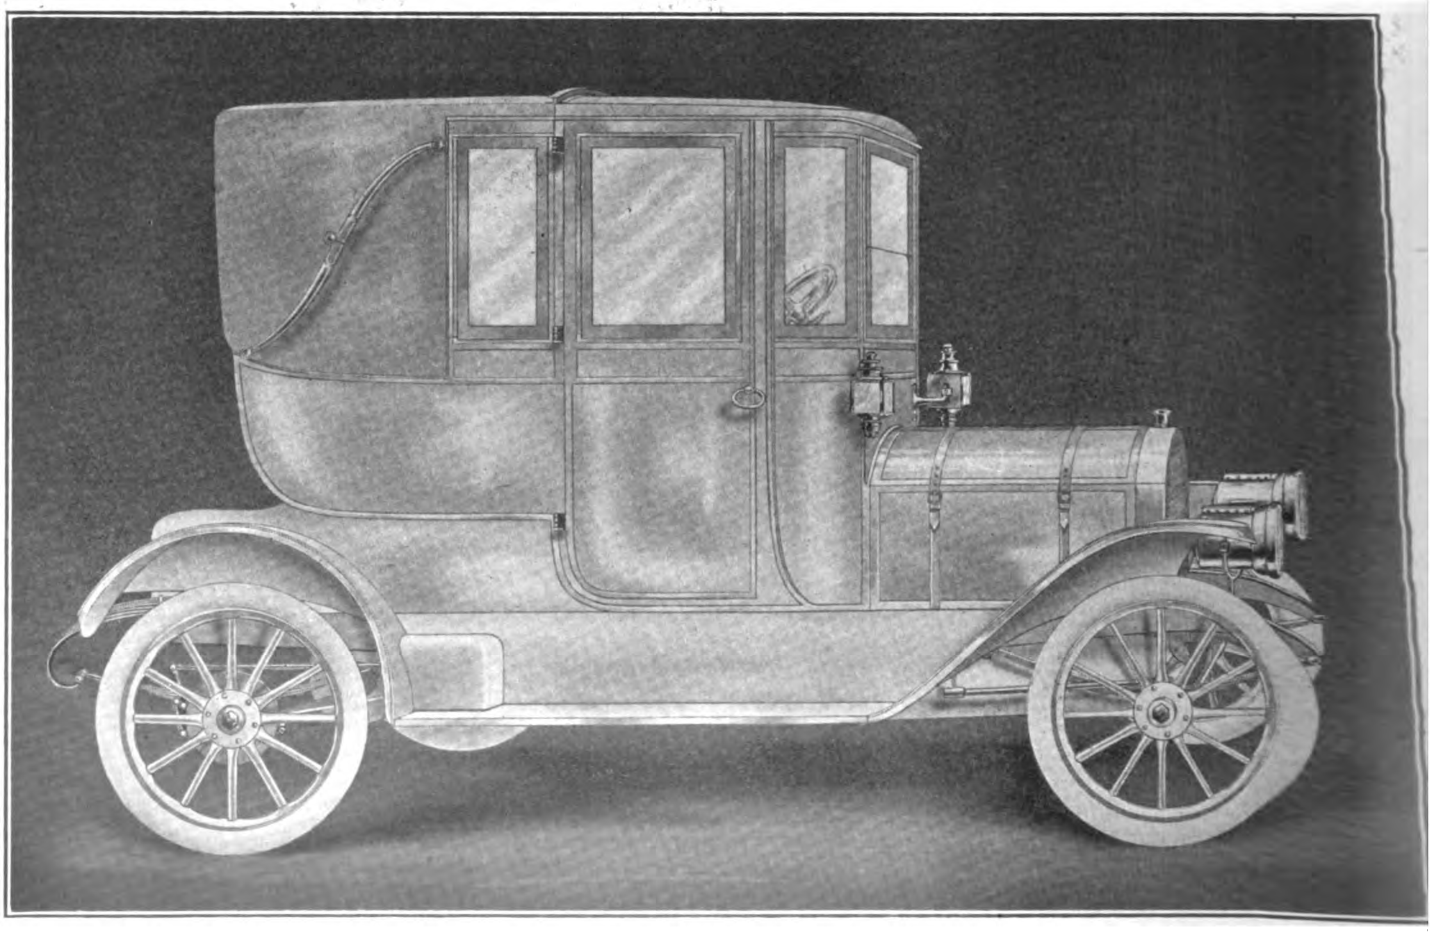


FIG. 1—SHOWING A NEW TYPE OF BODY ESPECIALLY ADAPTED TO WINTER DRIVING AND TOWN-CAR WORK

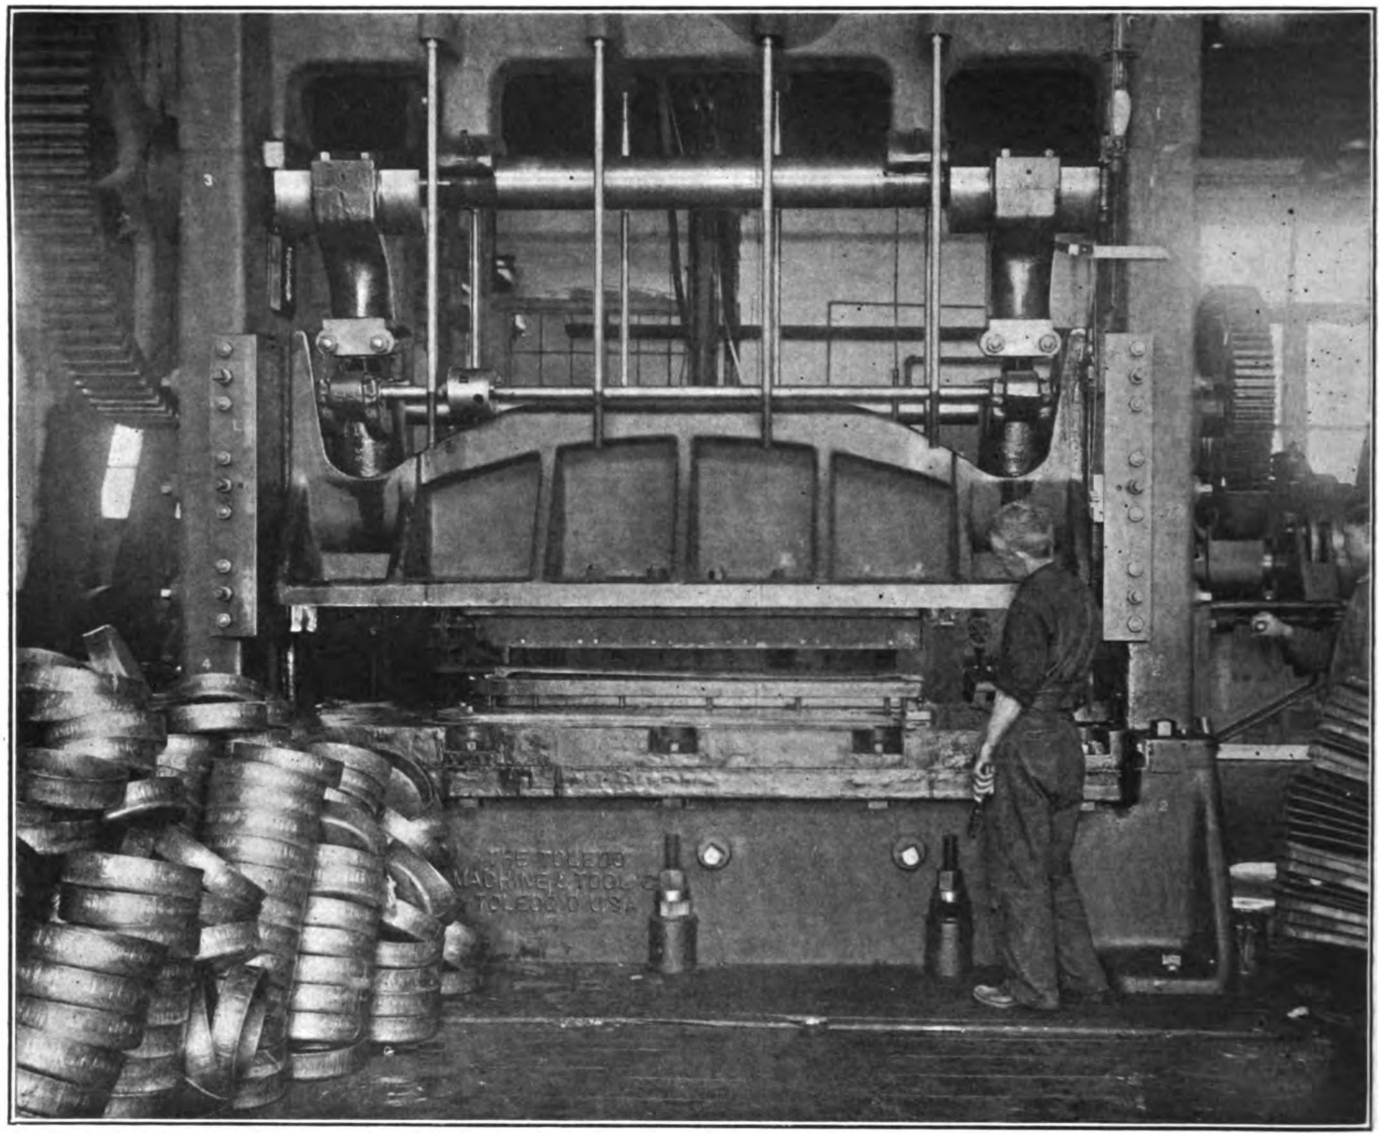
Among the Makers

EXCELLENT PROSPECTS FOR WINTER AUTOMOBILING—DETAILS OF THE 1911 CHADWICK SHOW A MATERIAL ADVANCE IN EXCELLENCE —THE NEW SPEEDWELL LINE



HOW BRAKEDRUMS ARE FORMED OUT OF SHEET STEEL—TAKEN AT THE MAXWELL PLANT AT TARRYTOWN

FOR a time it looked as if the 1911 models of automobiles would be much retarded, due to bad automobile weather last Spring and the enormous number of 1910 automobiles that were then contemplated. The present spell of good automobiling weather covers substantially the whole American continent, and this year differs from any previous year from the builders' point of view, from the fact that the demand for automobiles, ostensibly for Winter use, is greater than it ever was before. While it is true that the weather and the promise of a mild Autumn have much to do by way of encouraging automobilists, the fact remains that the new fore-door types of bodies, coupled with larger diameter wheels and better motor performance, remove the last obstacle that stood in the way of winter automobiling for pleasure.

But it is not the prospect of pleasure alone that serves as the motive for spending money on automobiles to be used in the winter time. When the snow is deepest and the weather conditions discourage every other form of transit to an absolute shut-down, thus stagnating business and serving as the basis for great commercial loss, the automobile is the one remaining type of vehicle for transportation purposes that has within itself the inherent qualities to combat the elements and deliver the lucky owner to his place of business on time in the morning and back to his place of abode in fettle for dinner, and ready to admit that he may have saved the price of a good automobile in a single day.

Even if it is not possible to trace so large a saving in so short a time, the economic advantage is sufficiently definite to be well worth taking into account, and to this is added the pleasure of living in comfort and in contentment.

The cost of living in the manner that requires the use of an automobile is reduced to a low ebb when account is taken of the greater amount of work that the owner can do.

The Chadwick for 1911

ALL FOUR MODELS ARE MECHANICALLY IDENTICAL—WHEELBASE OF THE RUNABOUT SHORTENED TO FACILITATE EASY HANDLING AT HIGH SPEEDS

MECHANICALLY and in general details of engineering design the 1911 models of the Chadwick, made by the Chadwick Engineering Works, of Pottstown, Pa., are identical, the only difference between the five- and seven-passenger types being the weight of the springs and the set of the steering gear. In the Runabout, or two-passenger model, the wheelbase has been considerably shortened to facilitate handling at high speeds and in addition it is equipped with special long-distance oil and gasoline tanks.

The Touring Car model is a 133-inch wheelbase chassis fitted with 36 x 4 tires in the front and 37 x 5 in the rear. The tonneau is large and comfortable, and the auxiliary seats when folded up occupy very small space in the tonneau. The rake of the steering gear, the finish and upholstering are all that can be desired. The standard colors are Brewster green and Chadwick red, upholstering to match. The standard equipment consists of demountable rims, tire brackets, robe rail, a foot rail, full set of tools, a 10-inch searchlight, with Prest-O-Lite tank, combination electric and oil side and tail lights, and storage battery.

There will be two Tourabout models offered. The miniature tonneau Tourabout, seating four passengers comfortably or five closely, the body design being extremely low and rakish with extreme rake to the steering gear, is furnished in Royal blue and Brewster green. Tire equipment is 36 x 4 1-2 front and rear, demountable rims. The standard Tourabout, a full five-passenger car, with detachable tonneau with double side doors, will prove unusually interesting to those who do not desire the carrying capacity of a large touring car. In this model has been accomplished that which has so long been striven for, the production of a five-passenger car which will possess the easy riding qualities of the larger model.

The Runabout model is a 112-inch wheelbase chassis and has identically the same engine as the Tourabout and Touring Car models, the only difference throughout the construction being the shortening up to allow placing it in the shorter wheelbase. Possessing power, speed, flexibility, and ease of operation to the greatest possible extent, and having on the high gear the ability to throttle to six miles an hour with an ultimate speed of ninety miles, this car is equipped with a luxurious and carefully worked-out body whose lines are graceful, attractive and symmetrical. It is not only adapted for high speed work, but is equally available for park or city driving or long-distance touring. The carrying capacity of gasoline is 50 gallons and of lubricating oil 23 gallons, enabling one to be independent of the base of supplies.

The type-19 engine shows the following improvements and refinements. The carbureter has been increased in size; around the inlet manifold has been placed a heating attachment not only enclosing the manifold, but the heater pipe also passes directly through the center. This will enable the low grades of gasoline now obtainable on the market to be used satisfactorily, and when the car is throttled down very low on direct drive there will be no difficulty experienced from condensation of the gas in the inlet manifold. The heating arrangement is so designed that the temperature of the inlet manifold can be maintained at any point up to the temperature of the heating water, enabling it to be instantly adjusted to meet the conditions found in different parts of the country. A special flooding device and air shutter have been installed for the purpose of easy starting. The spiral advance on the magneto used in former models will be maintained, with a slight increase in size and the addition of an outboard bearing in order to reduce to a minimum the wear and lost motion, and tending to greater quietness. The inlet valves have been largely increased in size and placed in the head of the motor, actuated by push rods and rocker arms, their connecting valve lifts being made instantly adjustable in order to insure noiseless operation. All points and working parts are carefully ground and case-hardened to insure long life. Inlet and exhaust springs are carefully faced square and have been slightly stiffened. There has been a slight increase in the size of waterjacket, due to the changing of the valve position, and the jackets in conjunction with the radiator carry nine gallons of cooling water. The pump has been placed on the left side of the engine, inserted in the oiler drive line with an Oldham coupling, and is easily removed. The oiler has been increased in capacity and is now furnished with a large filler hole, one of the small details that tend to greater satisfaction. The Herz distributor has been removed from the rear of the engine and placed in a most accessible and well-protected position on the left side, well to the front, being mounted vertically and driven from the pump line shaft and actuated by a spiral advance similar to that of the magneto. A separate set of plugs has been installed for the auxiliary system, which furnishes a complete double system of ignition and prevents trouble. The time gears are all of hardened steel, are carefully cut, and accurately ground and fitted to insure their quiet and smooth operation. The installing of hardened-steel time gears absolutely insures long life and durability.

The clutch is of the internal expanding type, actuated by a rack and pinion, and held into engagement by a very light spring pressure. The process of engagement is very smooth, being free from jerking or gripping. The flywheel is 18 inches in diameter, with six-inch face. The expanding band of the clutch is leather-faced at point of contact with flywheel. A strong feature of this clutch is the fact that by removing three nuts the band can be slipped out and the condition of the leather face examined or treated if desired, and band reinserted without disturbing in any one particular its adjustment. The foot lever operates the usual type of yoke, actuating a sleeve which carries a small rack operating a pinion and radial shaft inside of the clutch, the outer end of this clutch carrying a small crank surrounded by a hardened-steel roller. The rotation of this crank by the change of position of the clutch pedal forces the band in or out of engagement with the flywheel. There is attached to the body of the clutch a drum, and as the pedal is actuated to throw the clutch out, the small brake passes down beside the drum and prevents the clutch expanding. This brake is so designed as not to interfere with the clutch adjustment, and in case incorrect adjustment is made, it would not prevent the clutch being entirely disengaged.

The universal joint is not in the ordinary acceptance of the term a universal joint, but a flexible joint made of chrome nickel steel with pins, ball-shaped on the end, of chrome nickel steel, heat treated, the joint being respectively keyed to the drive shaft on the transmission and the connecting drive shaft between the clutch and the transmission. This joint, after many thousands of miles' operation in high-powered cars, has shown no signs of wear.

The drive shaft is of special heat-treated steel, flanged for carrying the clutch body integral.

The transmission is the Chadwick semi-selective type, three positions being located from the neutral, namely, first, second and reverse; the gear-shifting lever being equipped with a ratchet device which positively locks each gear shift in its correct relation and prevents passing through or improperly meshing gears. The principle of the Chadwick transmission lies in the large bevel gear in the rear, the intermediate drive being directly from the

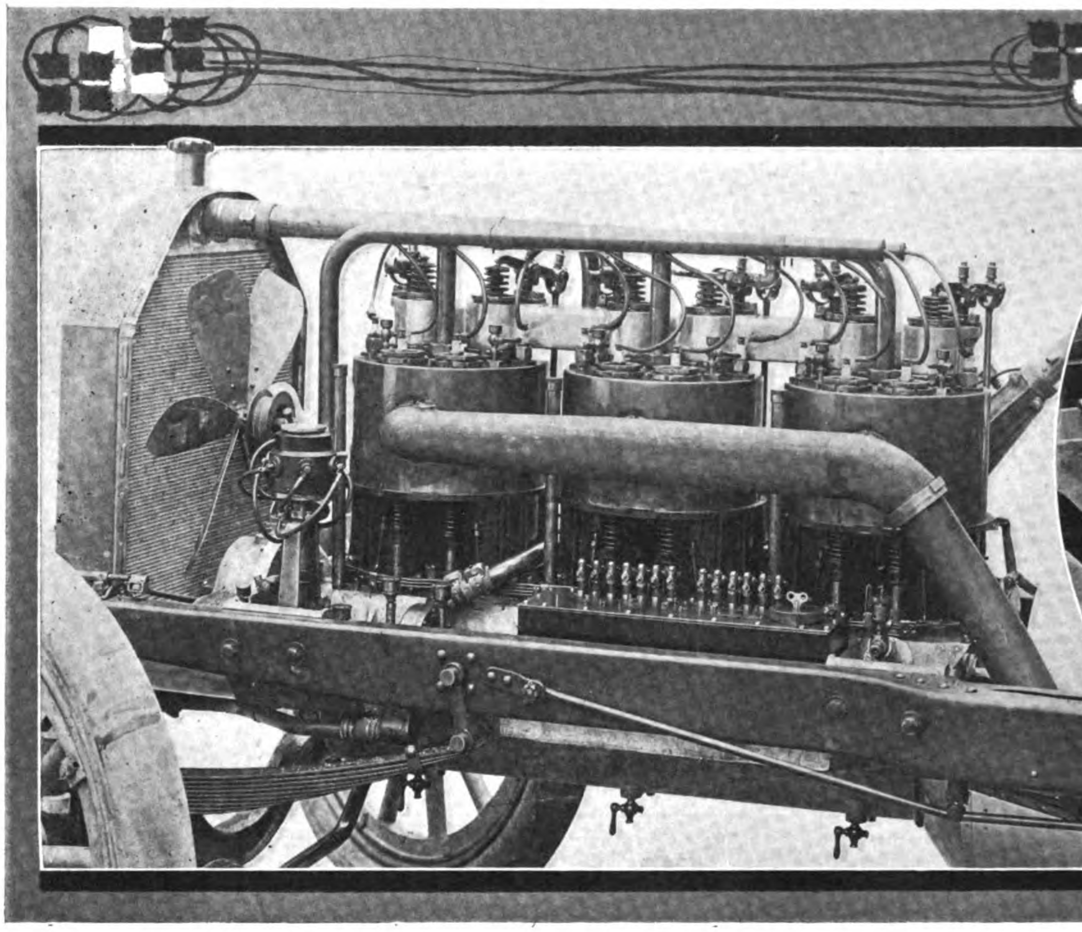


Fig. 1—Left-hand side of engine showing lubricator, timer and other details

Fig. 3—Detailed view of clutch mechanism, show

drive shaft to the counter shaft and to one set of double bevel gears, drive being through the line shaft directly to the other set of bevels, with direct drive on fourth. The gear ratio is 2.25 to 1 on the Touring Car and Tourabouts. Gears are of a special alloy, heat treated, and where possible the gears are forged integral with their shafts. The bearings are all unusually large, imported, all gears being carefully cut and accurately ground to insure their quietness of operation. A filler plate for grease is installed in top of transmission and at all points where shafts enter or leave the transmission carefully designed grease retaining devices are installed.

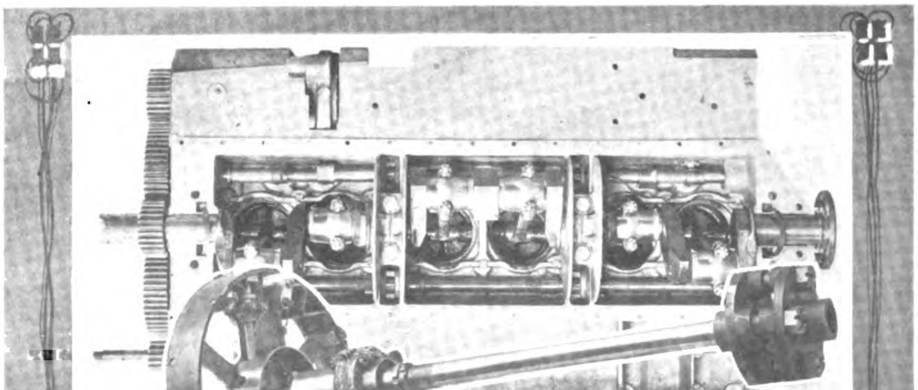

Fig. 2—Looking into the crankcase with its lower half removed

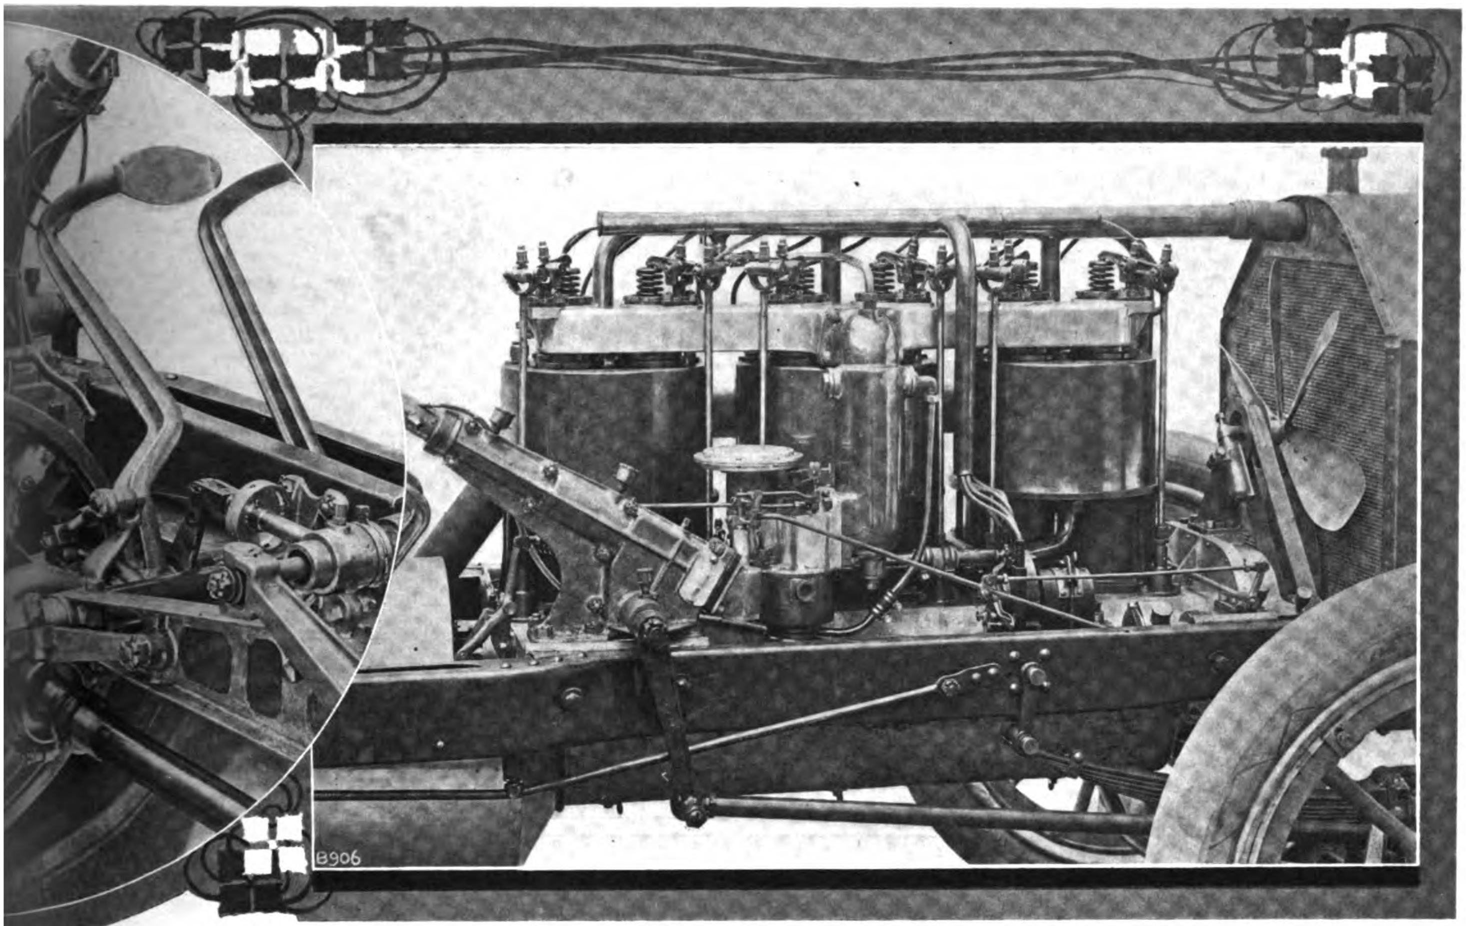
The chain drive is of the Chadwick type with enclosing chain case, whose principle lies in the employment of a radius rod forming the major portion of the chain case. This radius rod is a large, carefully designed manganese bronze casting, ribbed to obtain enormous strength with minimum weight.

The chain cases are dustproof to insure that the chain shall operate under the most favorable conditions, it being properly lubricated at all times and no opportunity allowed for dust or dirt to get on it to cut it out. This type of drive tends to work with the springs to secure greater ease of riding. The differential gear is incorporated with the transmission, and in the rear is employed an I-beam section axle of chrome nickel steel drop-forged in one piece, which possesses a wide mar-



substantial frame and part of propeller shaft

gin of safety and is not subject to distortion from road shocks. This type of construction transmits to the rear wheels the maximum amount of power, assures greater life and durability, with a wider margin of strength than has ever before been obtained, and also assists the designers in securing a car of minimum weight and maximum strength.

The braking systems are large and powerful, the main or service brake being actuated by a foot pedal and acting directly upon a large crucible-steel drum bolted directly to the compensating case. The brake shoes are equipped with cast-iron liners, the brake drum being 14 inches in diameter with 3-inch face, with cork inserts and producing instant locking action to the rear wheels if desired.

The placing of the brake upon the compensating case insures absolute compensated braking action, for at every turn the equalizing gears operate, with consequent assurance of their being in perfect condition. At high speeds it is of the utmost importance that brakes shall apply equally and there is no engineering design whatsoever that will give absolute assurance of this except the placing of a brake on the compensating case and braking through the equalizing gears. All adjustments are by hand, automatic locking devices being provided, these being some of the small refinements which must to-day be found on the high-powered, high-priced car. The rear or emergency brakes act directly upon the rear-wheel drums and are

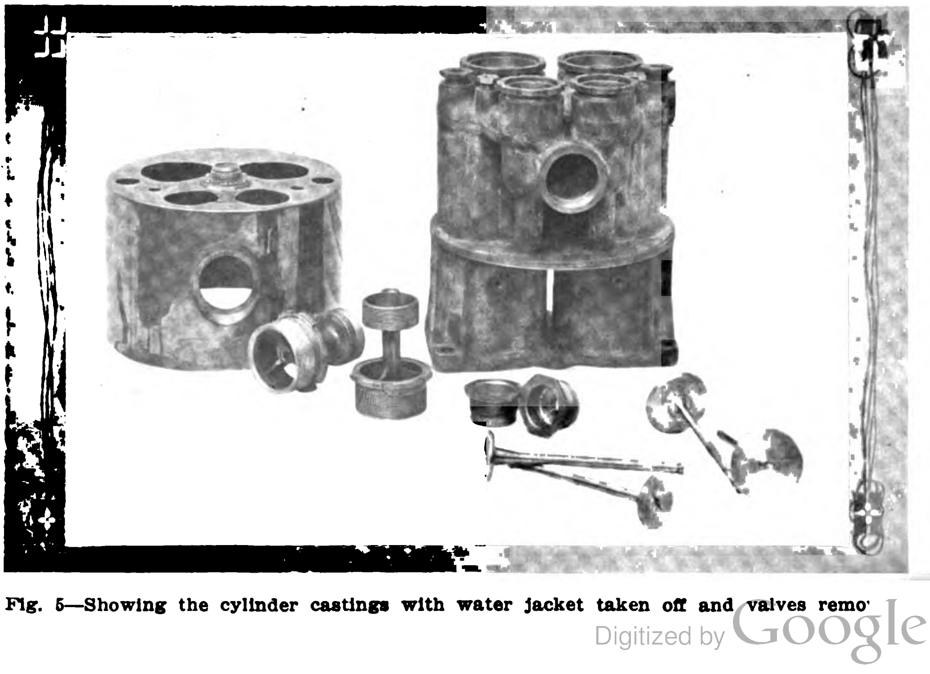

Fig. 5—Showing the cylinder castings with water jacket taken off and valves remo

operated by a hand lever. They are large in size, dustproof, manganese bronze to crucible steel, adjustments being made by hand.

In the Touring Car and Tourabout models the spring construction is semi-elliptic front and platform spring suspension rear. The front springs are equipped with a special safety link. This link is a patented Chadwick feature and absolutely provides against any danger of ditching due to loss of steering from front spring breakage. Owing to the engine being a dead load, the spring action in the front is further controlled by the equipment of Truffault-Hartford shock absorbers.

The platform spring extension in the rear has been carefully worked out, the springs are bushed, eyes being perfectly parallel and springs equipped with force-feed oilers, ample clearance being allowed for spring action. The Chadwick car has been noted for its unusual qualities of easy riding and this comes about largely from the carefully worked out and satisfactory spring suspension.

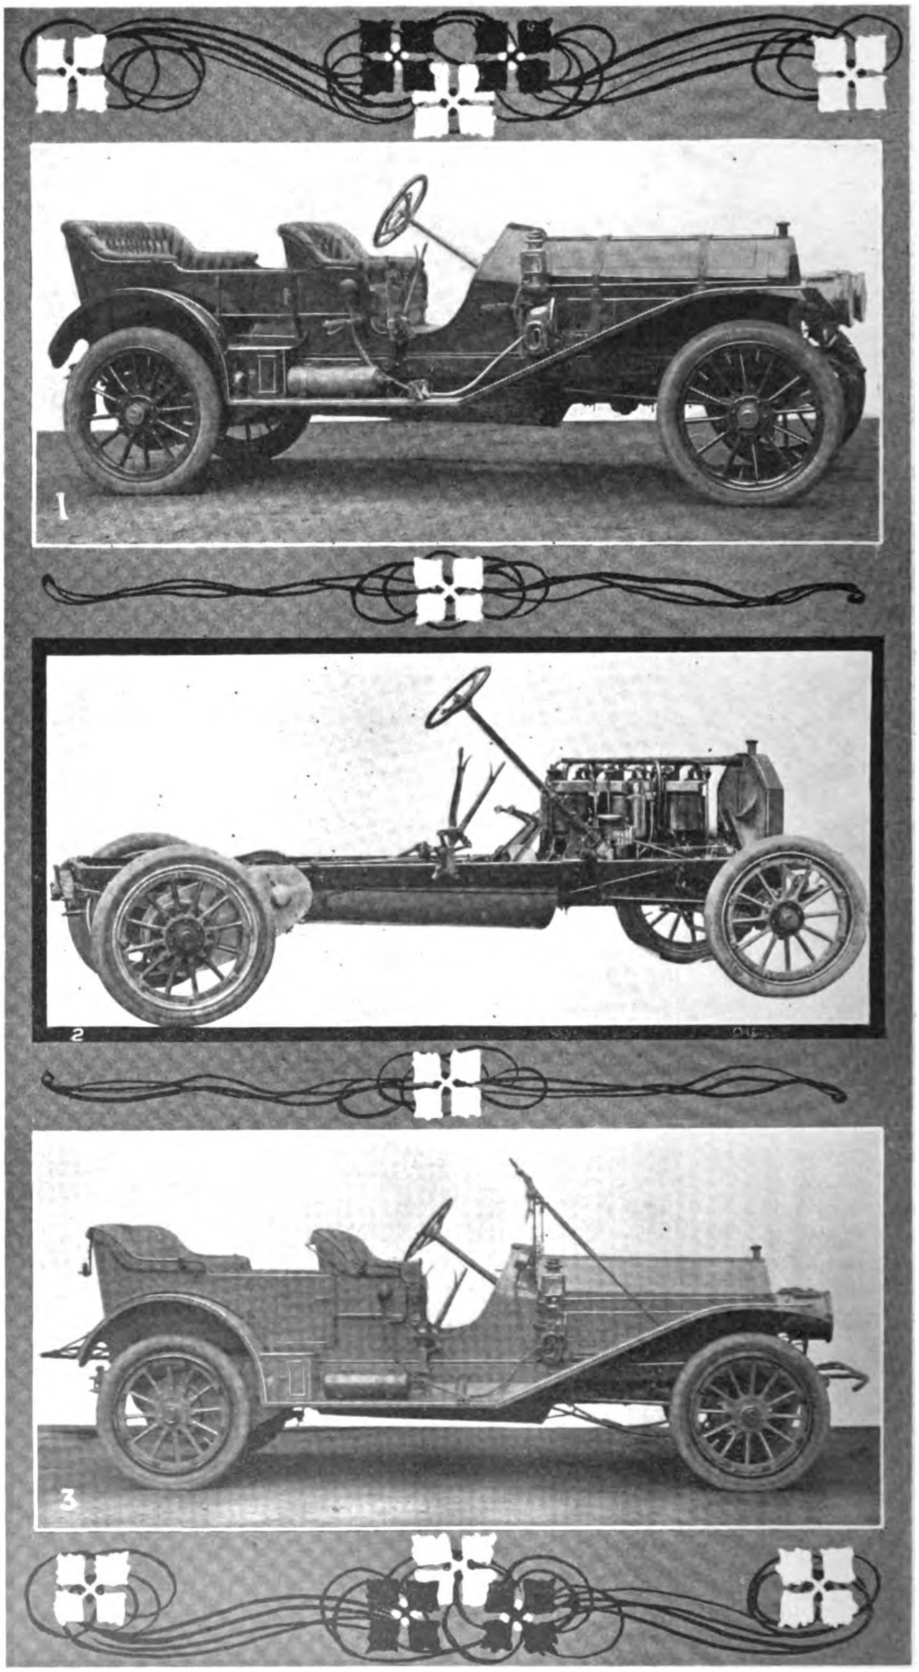
Runabout models are equipped with semi-elliptics front and rear. All springs are of vanadium steel with ample leaves, so that breakage is practically unknown.

The worm-and-screw steering gear is of the reversible type, equipped with 19-inch steering wheel, and remarkably quick in operation, giving a full sweep of the front wheel in 1 5-16 turns of the steering wheel. The steering gearcase is phosphor bronze and arched with a long supporting arm, so used that no dependence is placed on dash support to hold the steering column. To prevent road shocks being communicated to the gear, the steering axle bolts around which the front wheels revolve as a center are so inclined that shocks will be absorbed into the axles, and through the springs instead of through the steering gear connections—a most important point. Provision is made for adjustments which can be made without dissembling the gear. The side link connecting the steering knuckle arm, also the cross link which is at the rear of the front axle, are fitted with ball and socket ends so arranged that if the cap should unscrew and come out it would be impossible for the ball to come out of the socket, owing to the method of assembling.

Both front and rear axles are of I-beam section, chrome nickel steel, drop-forged in one piece. These are the type of forgings which are hammered and the constant pressure of the metal tends to make them enormously tough. They are heat-treated to give the maximum strength. The steering axles and steering axle levers are also of special alloy steel, as are the materials throughout the car.

The wheels are built of the finest grade hickory stock, having specially designed rosettes on the spokes for carrying the drums. The wheel bearings are all imported and several sizes larger than the loading would require and there are provided between the inside and outside bearings spacers so designed that if a ball should break, instead of grinding out the race the bearing will immediately change to a plain bearing and run upon the spacer. This spacer also serves the function of preventing the wheels from coming off.

The frame is of chrome nickel steel, channel section, heat



Miniature Tonneau Tourabout, seating chauffeur and four passengers
Right-hand side of 133-inch wheelbase chassis
Standard Chadwick Six Tourabout, seating capacity five

treated and bottle neck to allow short turning, and at the point where the frame is narrowed at the bottle neck there are supporting reinforcing gussets installed. All cross-members are of chrome nickel steel, heat treated.

Ignition is by means of Bosch high-tension magneto positively gear driven, the advance and retard being obtained by means of a spiral advance. The circuit-breaker is fixed in a permanent position to give a maximum intensity of spark at all positions of advance or retard, a fat, hot spark being obtained which enables the car to be throttled down very low on direct drive. The auxiliary system consists of a Herz low-tension timer with high-tension distributor and a single coil box on the dash with storage battery and a separate set of plugs, so that the two systems are entirely independent of each other, the auxiliary system being used for purposes of starting only and, where necessary, in an emergency. The car can be started on one-quarter turn of the crank on the magneto alone. The usual number of spark and control levers are provided on the wheel, except that they are very substantial and in addition to this the magneto cut-out button for the purpose of grounding the magneto is placed upon the steering wheel instead of upon the dash and in descending steep hills the engine can be used as a brake if desired. The magneto is held by means of a strap and winged nut, being located by dowel pins, so that it can be quickly removed for purposes of inspection.

Lubrication is by means of a Precision oiler, 14 feeds, there being an oil lead to each of the pistons, to each of the main bearings, to each of the crankcase compartments and to the compensating case in the back, the lead to the compensating gearcase passing through a bleeder test valve on the dash, which shows whether or not there is oil in the tank. The oil leads to the pistons lubricate the cylinder walls and also pass through the hollow wrist pins, lubricating the upper ends of the connecting rods. The leads to the main bearings lubricate these bearings and the oil passes through them to the connecting rod bearings, the crankshaft being equipped with a banjo oil catcher which throws oil in to feed the connecting rods. The front and rear bearings are also ring oiled, there being sufficient oil underneath to insure the delivery of the lubricant to them in addition to the force feed of the lubricator. In addition to this there is a receptacle in the base which furnishes a separate and distinct system of splash lubrication. After a lubricating oil has passed through a bearing its physical character is changed, and to insure as near perfect lubrication as can be secured fresh oil must be supplied to each and every bearing, which cannot be obtained other than by a positive force-feed lubricator supplying fresh oil. The lubricating system of the Chadwick engine has been most carefully worked out. The oiler is so designed as to furnish instant adjustment so that any desired quantity of oil can be fed to any particular point.

Considered from the price standpoint, the Chadwick 1911 proposition stands thus: Touring Car, Miniature Tonneau Tourabout and Standard Runabout each $5,500, f.o.b. Pottstown; Limousine, $6,500 f.o.b. Pottstown.

1911 Gemmer Gear Offering

THREE TYPES OF STEERING GEARS SHOWN; MODELS "O" AND "K" ARE WORM-AND-SECTOR TYPES; MODEL "G" IS THE CHARACTERISTIC GEMMER GEAR

AUTOISTS of experience now regard steering gears as entitled to the most exacting consideration, and they demand that the design, construction and material used in this part of automobiles be of the best. The requirement, from the necessity point of view, contrary to the usual way of looking at it, depends upon the conditions as follows:

(a) Considering the square of the speed of the automobile;

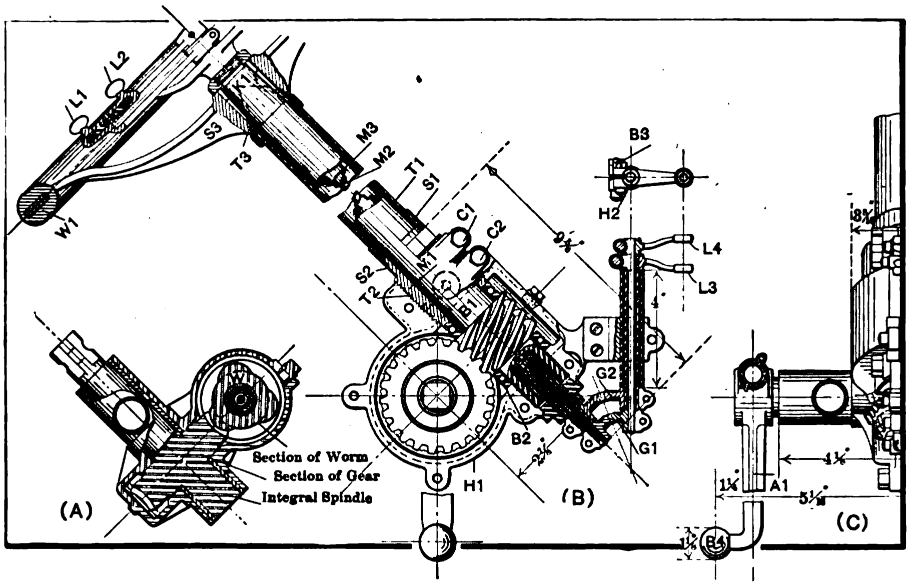

Fig. 1—Model K gear of the worm and gear type with ball thrust bearings above and below the worm and liberally proportioned plain bearings for the gear shaft

(b) Involving the weight of the car;

(c) Viewing the design of the front axle;

(d) Locating the center of gravity of the structure;

(e) Noting the fore-and-aft distribution of the weight;

(f) Influenced by the diameter of the road wheels used.

Just using what might be termed a good steering gear, not figuring upon all the influencing considerations, as will be plainly seen, is not the right way to arrive at the right conclusion, and as the Gemmer Manufacturing Co., of Detroit, Mich., has pointed out, the proper use of steering gear requires mature consideration. The company makes a specialty of this character of work, and in addition to a large and well equipped plant, it is provided with all the means for determining the best conditions to surround each of its makes of steering gear.

The illustrations here afforded of three of the Gemmer types of gear, while they do not cover the whole range, are sufficient to illustrate the points to be made, in which quality of material is the first requisite, but, as will be shown, there are other equally or more important details that must be attended to if the end is to be entirely satisfactory.

In Fig. 1 of the Model K gear reference will be made to a section of the worm and gear (A) with a view to making the point that the material used is of a fine grade of true cementing steel, and it is heat treated to render it glass hard, but the core is left in a state to resist shock. It is too frequently overlooked in this class of work that mere low-carbon steel is not sufficient for the purpose. True, it is possible to employ ordinary grades of low-carbon steel in cementing work, but when the product is finished it can not be claimed that safety is one of its properties, and when this important point is disregarded in steering gears it looks as if the greatest question is ignored. Considering (A) in Fig. 1, the worm is of the cementing steel referred to, and it is first machined to near size from bar-stock, then machined to accurate blanking size, after which the worm is hobbed, leaving "grinding finish" over the diameters of the two extremities of the integral spindle. The next step is to pack the worms in bone in a box, after which the cover is put on, and luted, to keep it tight against the introduction of any contaminating substance, also to keep the gases from the bone in long enough to cause carbon to penetrate below the surface of the metal for a suitable distance to afford the hard skin; but the fact that the metal is of true cementing stock assures that the penetration will be limited to that definite amount that is known to suffice for the purpose, leaving the core soft and dynamic.

Passing on to the remaining things to be noted, B1 is a thrust ball bearing above the worm, and B2 is a similar bearing below the worm, as shown in the section (B). The housing H1 is a close fit, made in the shape that affords the requisite strength, and is so designed that it goes readily into place in substantially every make of car; in other words, it is approximately universal. The steering post tube T1 is accurately fitted to the housing by means of a sleeve S1, butting up against the shoulder S2 of the member M1, and the housing H1 is split at this point so that, by means of the clamping bolts C1 and C2, a secure relation is realized, but this relation is aug-

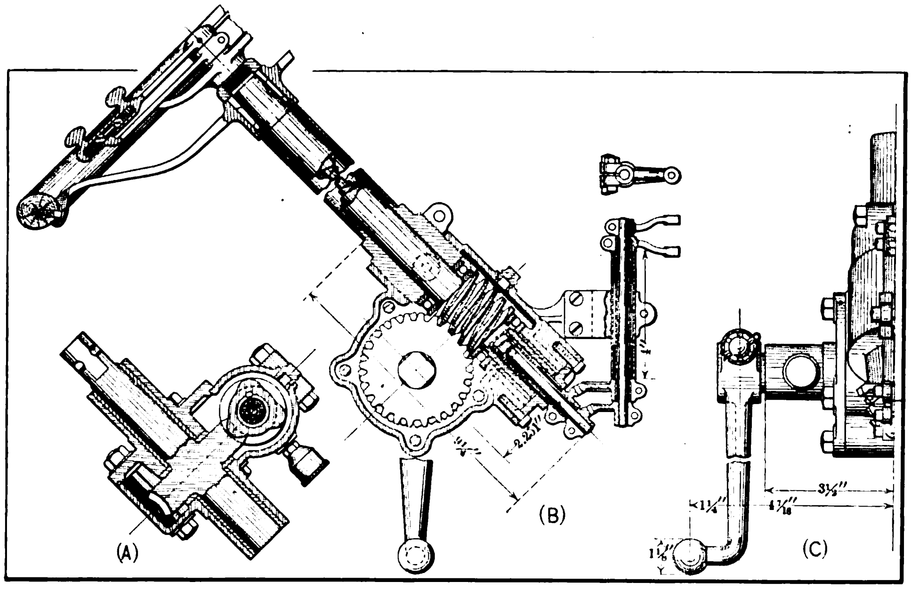

Fig. 2—Model O gear of the worm and sector type, differing from Model K system in detail

mented due to the use of threads T2 which are chased in the housing H1 and mated on the member M1. The spider S3 of the steering wheel W1 is fitted over a taper T3 and Woodruff keys K1 are employed to prevent the spider from rotating excepting with the tube. The spark and throttle levers L1 and L2 shown in part section are above the steering wheel and they impart motion to the torsion members M2 and M3, thence to the bevel sets G1 and G2, from where motion is directed to the mechanisms on the carbureter and magneto. Either the system G1 or G2 may be used for the magneto, the remaining system being for the carbureter control. An examination of the plan will show the nice designing of the small levers, which are made with split hubs H2 rendered secure by means of clamping bolts B3. Referring to Fig. C and to the steering gear arm A1 with its large diameter ball B4, the extension of the arm is square, and the hole in the arm is broached square.

For a certain class of work, notably on cars of lower power and speed than when the gear as above described is used, the gear as shown in Fig. 2, known as type O, is used. Fig. 3 is an illustration of the characteristic Gemmer gear.

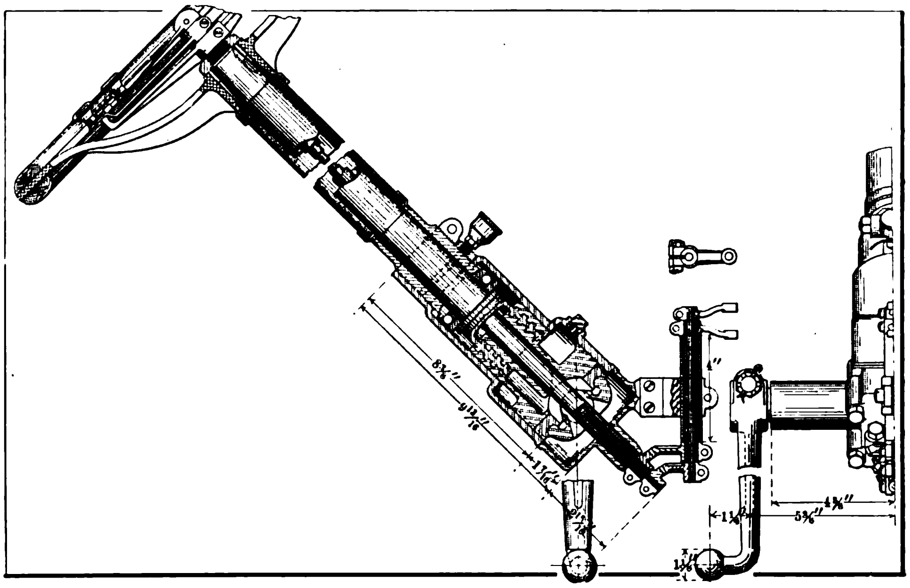

Fig. 3—Characteristic Gemmer gear as used under the most exacting conditions of service

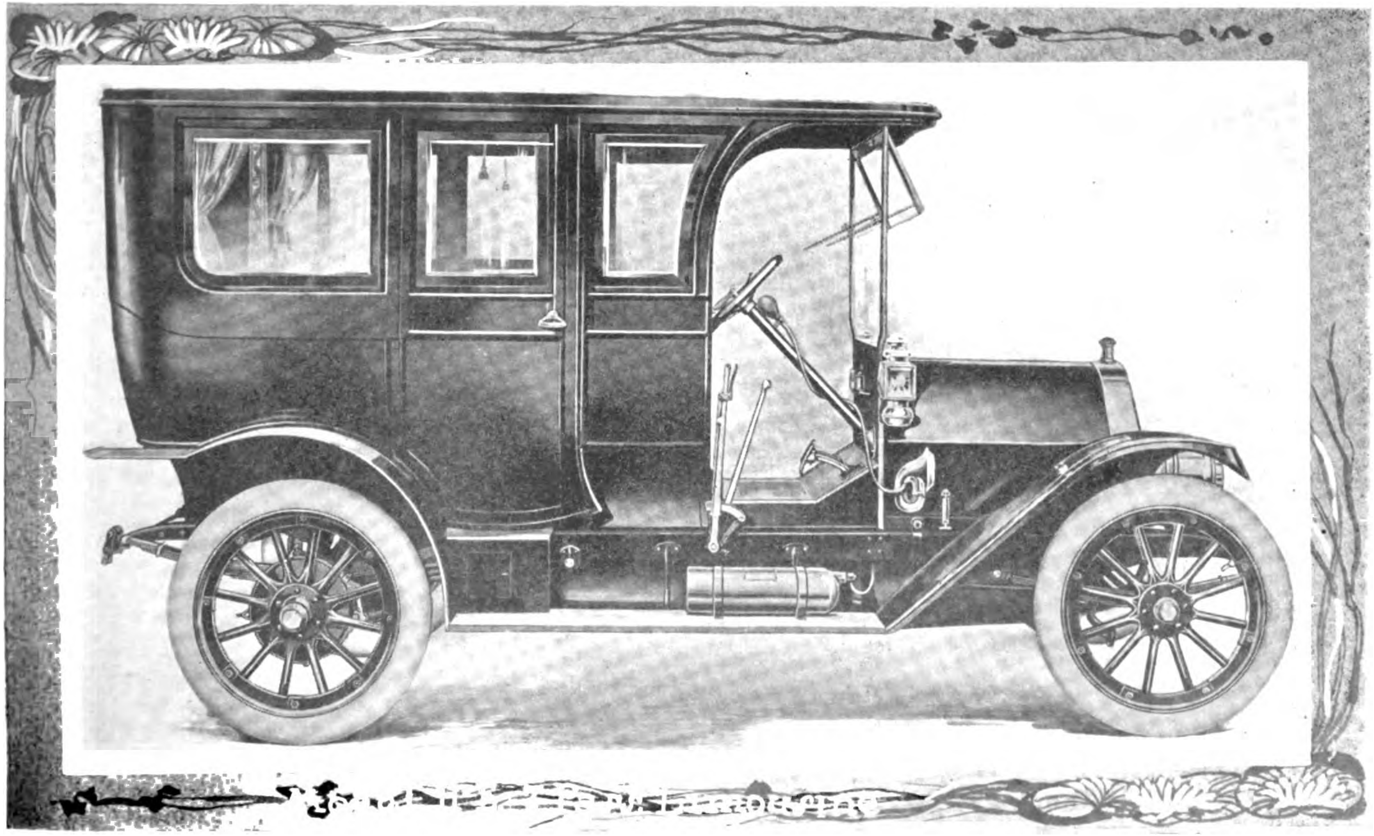
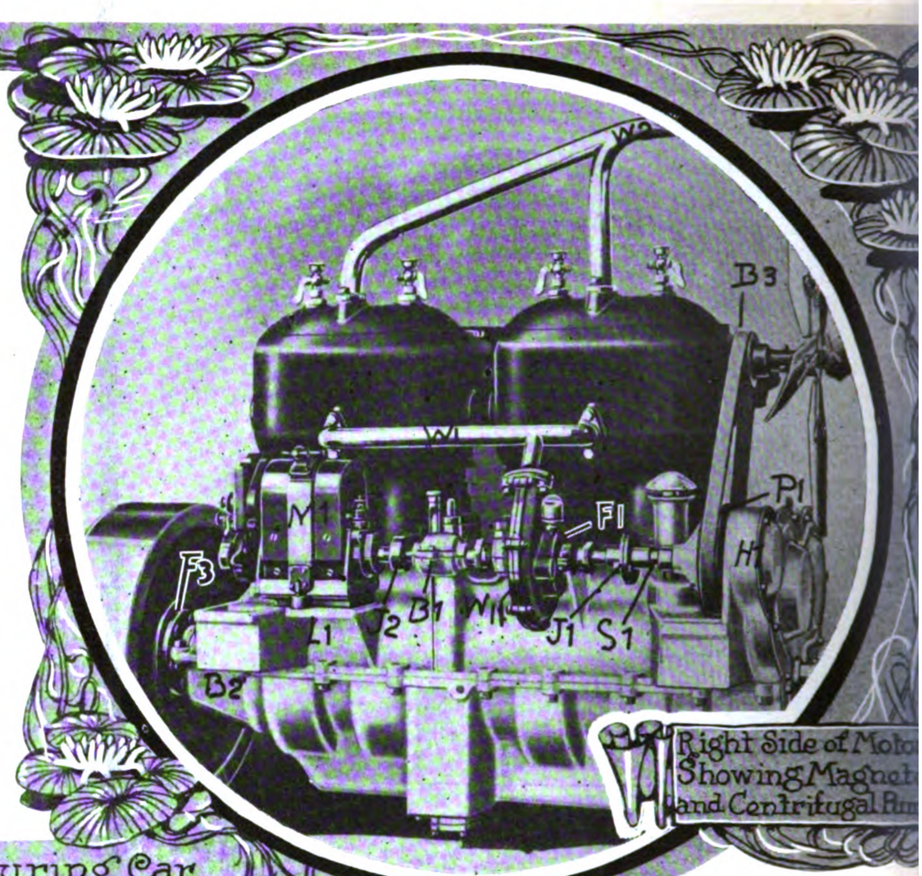
1911 Speedwell Automobiles

ELEVEN OPTIONS TO THE PURCHASER; POWER PLANT COMMON TO ALL; REFINEMENTS RATHER THAN CHANGES PREVAIL

TAKING a single power plant and fixed conditions of the chassis with a wheelbase of 121 inches and standard tread the Speedwell Motor Car Co., of Dayton, Ohio, provides eleven types of cars for the various classes of its clientèle, the lowest of which sells at $2,500 in the form of a fore-door roadster, and the highest priced car sells at $3,850 with a limousine body. The tabulation as here afforded gives the necessary information in relation to the several options. The tire equipment is 36 x 4 on all four wheels of the respective models, and referring to the view of the stripped chassis, the general arrangement of the





Right Side of Moto
Showing Magnet
and Centrifugal Pu

units is clearly indicated, with the radiator R1 on the center line of the front axle, and the motor M1 far enough back to make room for the fan F1. The clutch C1 is housed in the flywheel; it is of the cone type, and a universal joint U1 is placed between the clutch and the three-speed and reverse selective sliding gear system G1. A second universal joint U2 connects the clutch G1 with the propeller shaft S1, and a third universal joint U3 makes connections with the live rear axle A1. The service and emergency brakes B1 and B2 are in drums on the rear wheels. The chassis rides on semi-elliptic springs S2 and S3 at the rear and somewhat shorter semi-elliptic springs S4 and S5 at the front. The scheme of design throughout is straight line, and provision is made for the equalization of the braking pressure by means of equalizers E1 and E2. In the steering mechanism it will be observed that the drag rod D1 is straight, and the tie rod T2 is not only straight, but it is in a protected position to the rear of the front axle, the latter being a drop forging of the I-section in one piece. The chassis frame is of the channel section, with crossbars at points of greatest necessity, and the power plant is supported on a subframe which terminates at a crossbar to the rear of the transmission gear.

The live rear axle of the Timken type, with a shell-like one-piece housing H1 with the differential unit D1 removed, shows the jackshafts J1 and J2 with square ends to engage the differential set through the broached holes B1. Gear ratios are 2 10-19 to 1, 3 to 1 and 3 3-7 to 1. The spring perches P1 and P2 are free to rotate, thus relieving the axle of spring contortions, and the brake drums B2 and B3 are of large diameter with wide-faced brake bands, B1, B2 and B3 of the constricting type actuated by the level L1. The internal expanding brake shoes are actuated by the lever L2. The shell-like axle housing H1 is of great strength, but in order to guard against any possibility of sagging the bobstay S1 is also provided. Timken roller bearings B4 are placed on the spindles, and the drive is made from the jackshafts J1 and J2 through dog clutches C1 to the road wheels. This type of axle affords immunity from the class of trouble that comes from axle sagging and disalignment. The Timken roller bearings provide against thrust as well as caring for the radial load, and they may be adjusted at will to compensate for wear. In the differential unit the bevel drive is incorporated, and the entire outfit is mounted complete in its housing, after which it is inserted into place in the enlargement of

Apple Dynamo

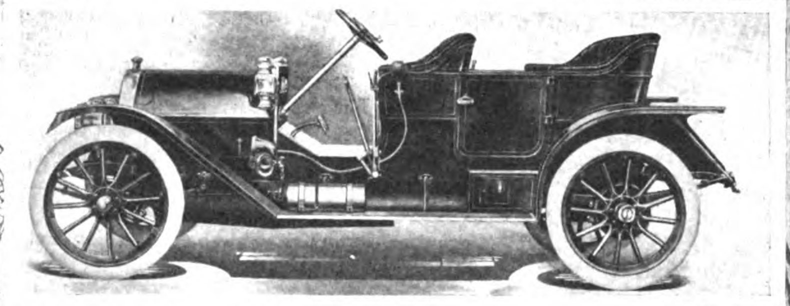
the shell, and noiseless performance is assured as well as ease of disassembling.

The 40-horsepower, four-cylinder, water-cooled motor has the cylinders cast in pairs with a 5-inch bore and stroke respectively; valves are on the left-hand side and are operated by a single camshaft. Referring to the illustration showing the left side of the motor, provision is made for an Apple lighting dynamo D1, resting on a ledge L1, driven by a pinion within the half-time housing H1, taking power from the half-time train, and the pinion is accessible through the cover C1. The carbureter is also placed on this side and is flanged to the manifold M1. The exhaust manifold E1 and the intake manifold M1 are held against flanged surfaces of the cylinders C2 and C3 by means of yokes Y1 and Y2, utilizing four studs S1, S2, S3 and S4, which are in a get-at-able position so that the time required to remove and replace the carbureter and the manifolds is reduced to a minimum. The lower half of the crankcase C4 is provided with an oil sump, and a plug P1 is so placed as to drain the sump and afford a means by which it may be flushed out. Referring to the view of the right-hand side of the motor, the magneto M1 is placed on a ledge L1 near the flywheel, and the water pump W11 is flanged to a face F1, it being the case that the magneto and the pump are driven by a shaft S1 taking power from the half-time gear case H1, and a flexible joint J1 is placed in front of the pump with a second joint J2 back of the bearing B1, but in front of the magneto M1. A flywheel F2 is flanged to the crankshaft at F3, and the rear end bearing B2 has a large projected area in order to support the weight and gyrations of the flywheel in addition to the torque of the motor. The water piping W1 is symmetrical and well made, and the water leading from the motor to the radiator is through a well-contrived water manifold W2 with a flexible hose coupling intervening. The fan F4 is substantially made, has a good propelling ability and is actuated by a flat belt B3, driven by a flanged pulley P1. The workmanship throughout is on a high plane and the general appearance of the motor accords with accepted practice along conservative lines.

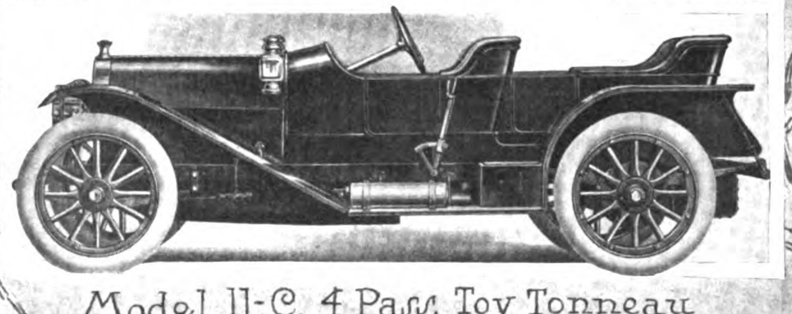
Ample cooling effect is given by an efficient cellular radiator, the water being circulated by a large centrifugal pump. Air is drawn through the radiator by a carefully-balanced fan, driven by an endless belt, any stretch in which may be taken up by an eccentric adjustment.

An 18-inch steering wheel with an aluminum web and Circassian walnut rim is used on all models. A worm and complete gear of vanadium

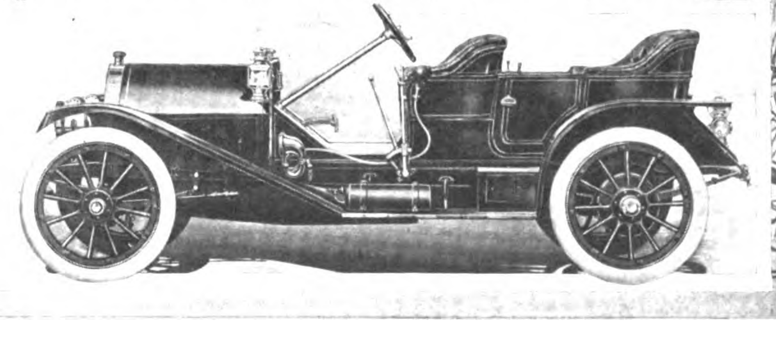
Model 11-K, Close Coupled 5 Pass. Car

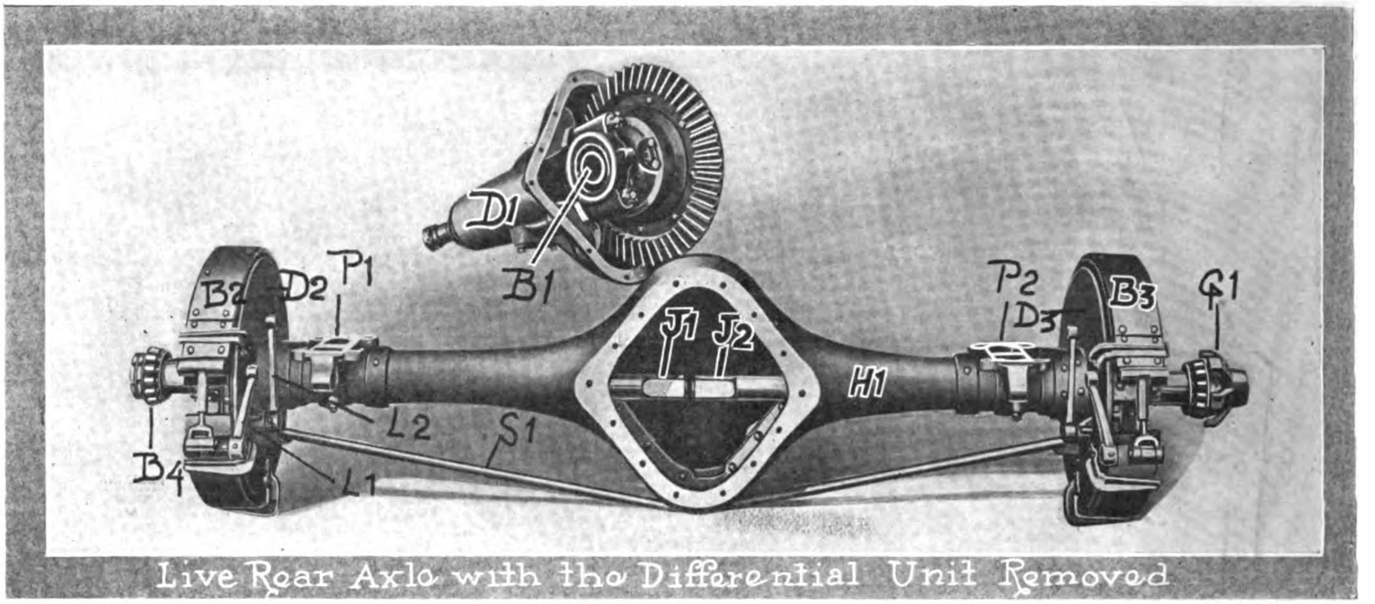


Model 11-H, With Toy Tonneau



Model 11-C, 4 Pass. Toy Tonneau





Live Rear Axle with the Differential Unit Removed

steel, carefully hardened and ground, are enclosed in a heavy housing with simple means of taking up wear in the bearings and between the worm and gear. A large force-feed grease-cup lubricates all frictional surfaces. The worm and complete gear type allows four changes of teeth, which is in strong contrast to all other types, which allow no change.

The semi-elliptic springs are made from the finest spring steel of special analysis, and are rigidly tested and inspected before being placed under the car. The springs are 2¼ inches wide and almost flat, very flexible, but of such toughness that breakage is almost impossible. The springs being flatter than in former models, the frame is 1½ inches closer to the ground. The front springs are 40 inches, the rear 56 inches long. Perfect alignment is maintained by small lips on each leaf. All spring eyes are provided with hardened steel bushings.

Unusually great braking power is provided—approximately one inch of braking surface to each seven pounds of car. The four brakes, of simple and heavy construction, act on rear wheel brake drums, an improved provision being made for all adjustments, although adjustments are seldom necessary. Both running and emergency brakes are provided with equalizers.

The Co-operator Favors Himself a Little

Methodic co-operation for industrial progress is fashionable among theorists only. The American citizen, native or naturalized, who fights for his country in times of peace fights a little more for himself than for the rest of us combined. But whatever he accomplishes, by making automobiles, for example, better suited for the needs of the masses or the classes, he has to share with all. He has to give value. Only his defeats are his own and remain so. They probably number ten, to one success, among the soldiers of peaceful progress. Yet only he who does not shoot is without honor—if he has gun and ammunition Methodic co-operation would save some of the misses, but, oh human nature unregenerated, the crown of reward for a bull's eye would descend upon the foxiest head in the combine, whose genus and whose genius no one wishes to have propagated or promoted to the seat of prestige. Gunning is as common as grass and prevails in co-operation, as in politics. It is gunning that is wanted, and a breed of gunners, fellows who can set their sights with little direction from the lieutenant and who can "go it" alone, having confidence in their own ability for discerning a target among the values of civilization. The journal of special purpose stands for all the co-operation the lone gunner wants, and he does not want it unless it shoots, too.

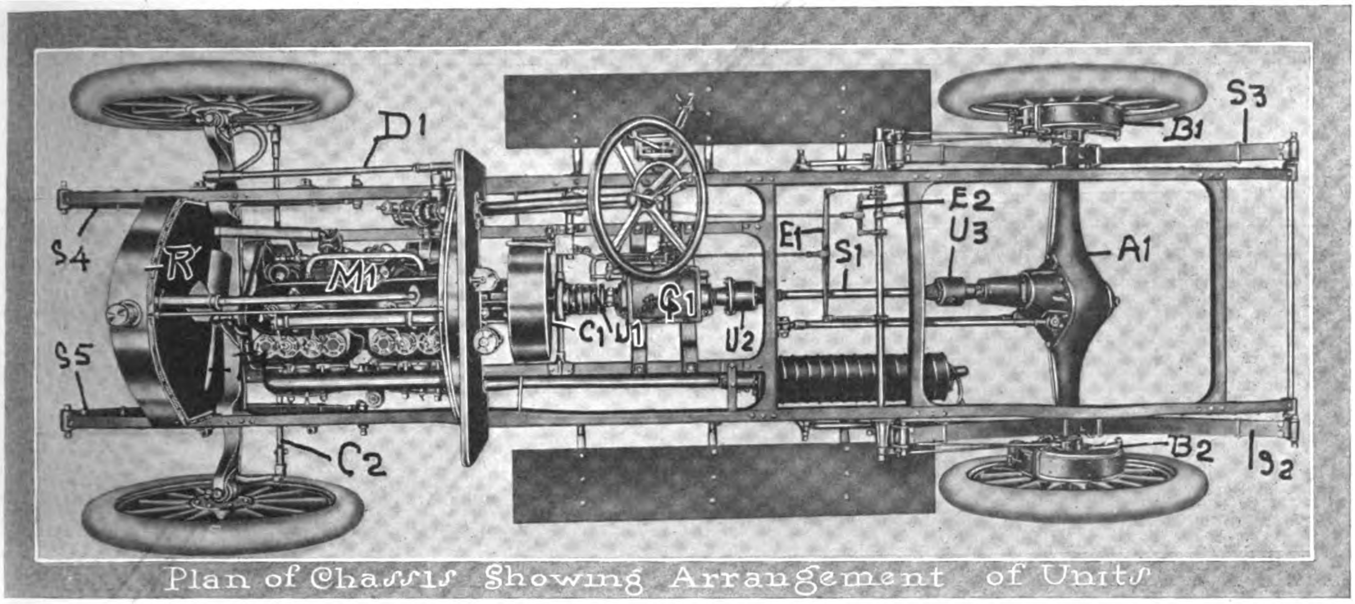
Will Coke Replace Benzine for Fuel ?

In the mechanical transportation of men and material on ordinary streets and roads the victory will be to that system, or those systems, where the cost of service and the duration of full efficiency without undue outlay for repairs are the lowest, and the degree of reliability the greatest.

The advocates of steam figure that a five-ton vehicle, running on streets and roads with over 10 per cent. grades, should be able to tow a 2-1-2 ton tender without trouble. A benzine motor to effect this would be of about 40 horsepower, and take 0.4 kilogram equals 4.88 pounds average of benzine per horsepower and per hour, which, at marks 30 per 100 kilograms equals $3.24 per 100 pounds average, would cost marks 4.88 or $1.14 per hour.

The steam-driven vehicle would, it is claimed, do the same thing all day with 400 liters equal 14.12 cubic feet of gas coke at mark 0.80 per 100 liters equals $5.39 per 100 cubic feet, costing only marks 3.20 = $0.76; that is, mark 0.32 = $.076 per hour.

The cylinders for the steam engine must withstand only 14 atmospheres pressure and a temperature of 190 deg. Cent. equal 384 deg. Fahr.; whereas those of the benzine motor need withstand a temperature of 800 deg. to 1,200 deg. Cent. equals 1,372 deg. to 2,192 deg. Fahr.



Plan of Chassis Showing Arrangement of Units

able rims are on all models but the 11-H, which has Goodrich quick detachable.

In the matter of price the Speedwell line offers an exceptionally wide range of choice. Commencing with Model 11-H, fore-door body roadster, at $2,500, there follow the 11-C toy tonneau, $2,625; 11-D touring car, $2,650; 11-K close-coupled, $2,650; 11-G "Torpedo," $2,700; 11-H Special, semi-racer, $2,700; 11-D special, $2,750; 11-F touring, $2,800; 11-F special, $2,900; 11-E Limousine, $3,850, and the "Cruiser," $3,500. The latter, a special 1911 effort, with a wheel-base of 132 inches, is a particularly rangy-looking car, and in addition to the regular equipment there are included a pigskin trunk and cover, cape top and shock absorbers.

CARS AS OFFERED FOR 1911

pe with toy tonneau rear.

Standard equipment includes a Prest-O-Lite tank with all models (except 11-H, which has a generator), two acetylene gas headlights, two side lamps, one tail lamp, horn, jack, tool kit, tire repair kit, pump, battery box, tool box, robe rail and Bosch magneto. Model 11-H Special has rear seats, same pitch as front, and pressure gasoline tank in rear.

Although it has never been the custom of the Speedwell concern to enter cars in road and track competitions, many individual owners have done so, and with marked success in some instances. In the Good Roads tour from Atlanta to New York a privately owned Speedwell was among the absolutely clean-score cars.

Losses in Economy with Alcohol Motors

The losses in economy with alcohol motors come under five heads: Those due to the work of drawing in and exhausting the gases of the charge; (2) those of friction of moving parts; (3) those caused by late and slow combustion, as shown by bad indicator diagrams; (4) loss of heat given out to the cooling water, and (5) passage of unconsumed alcohol through the machine. This latter, which is about the only loss in which the motors of various makes differ greatly, accounts for the enormous consumption of fuel of some motors under certain loads and conditions.

It must be noted in this connection that to insure complete combustion no more alcohol must be introduced into the ignition chamber than the air can properly supply with oxygen for combustion; and that the intermixture shall be so complete that even with exactly theoretically perfect proportions of alcohol and air, no uncombined air or alcohol shall be exhausted. A good instance of the truth of this is given by Meyer as the result of tests of two motors of equal size, and of the same builder, but in which the compression was in one case 5.91 times, and in the other 8.90. The first-named motor consumed 436 grams of 86.1 per cent. alcohol per horsepower per hour; the other, 364 per horsepower per hour under same conditions.

First Russian Touring Competition

The first Russian touring competition, from St. Petersburg to Witebsk, Gomel, Kiev, Moscow, Wischni Wolotschok and St. Petersburg, a distance of 1,900 miles, has been recently won by Willie Poege on a Mercedes, with Fritsch, also on a Mercedes, second; Valenski third on a Gaggenau, and Heine and Erle respectively fifth and sixth on Benz cars.

The five Mercedes cars taking part in the competition are similar to those which took part in the Prince Henry tour in Germany, their four-cylinder motors having a bore and stroke of 3 7-10 inches by 6 inches, with four valves in each cylinder. As the Gaggenau firm is practically a newcomer the winning of third place by it came as a surprise. Having come so successfully through the Prince Henry tour it was expected that the Benz would do better than fifth and sixth positions. A streak of ill-luck in the form of slight accidents, however, kept them back. At the start there were 43 cars; Germany supplied 26, France 8, England 3, Russia 3, Belgium 2 and Italy 1. Considering the state of the roads the rather high number of 35 cars which finished the tour is very satisfactory. Owing to the lack of hotel accommodations in the towns and villages passed through, a special train with dining and sleeping cars followed the competitors, carrying all their baggage.

Digest

EXTRACTS FROM CONTINENTAL JOURNALS ON SUBJECTS ALLIED TO AUTOMOBILE ENGINEERING: TWO CARBURETERS OF SPECIAL PURPOSE—AMERICAN KEROSENE NOT SUITABLE FOR MOTOR FUEL

Special adjustment of a carbureter for very low driving or for keeping the motor going while the automobile is at a standstill is provided by the German Daimler Company by means of the construction shown in the accompanying illustration, Fig. 1 A and B, with especial view to avoiding that fouling of spark plugs and combustion chamber which is likely to be the result of poor combustion when the motor, as ordinarily throttled, draws in a too-rich mixture. The jet *f*, fed from the float chamber *d*, terminates in the tube *b*, which is surrounded by the air chamber *a* and connected with the induction tube of the motor by the conduit *c*. In the cylindrical extension *g* is placed the sliding tube *h* which at its inner end carries a thin and bent tube *i*, open at both ends. In Fig. 1A, *h* is shown in the position for normal driving. The air channels are all open. In Fig. 1B, *h* is shown in the position which closes the connection between *b* and *c* and establishes instead the tiny tube *i*, one end of which is very close to the jet, as the only channel for the gas mixture.—*La France Automobile*, No. 35.

An improved constant-mixture carbureter, Fig. 2, has been designed by the French engineer Rebourg and has been tested with benzol as well as gasoline, in both cases resulting in greater flexibility of the motor. The jet *B* is surrounded with an air conduit shaped as a double cone and composed of a number of flexible brass strips which are twisted helically and overlap. These strips are secured at the bottom to a fixed ring *N* and at the top to the ring *D*, which is capable of a rotary as well as an up-and-down movement and provided with gear teeth. Centrally in the ring *D* there is secured a tube *E* whose lower portion telescopes around jet *B* when the ring *D* moves up or down and thereby covers or uncovers some of the apertures in *B* through which the fuel is discharged. When ring *D* is turned in the direction of the twisting of the brass strips, the central diameter of the air conduit *A*, is contracted, and at the same time its height is reduced and the ring *D* is lowered and a number of the apertures in *B* are closed by tube *E*. Turning of ring *D* in the opposite direction naturally has the opposite effect. The changes are worked automatically by the motor. To this end the diaphragm *G* operates ring *D* by means of the rack *C* meshing with the spur teeth of the latter. On the outer side of the diaphragm the atmosphere exerts its pressure through openings in *H*, and on the inner side the suction of the motor and the constant pressure of spring *R* take effect, the spring pressure being kept constant by means of the compensating device *LT*.—*La France Automobile*, No. 36.

Many persons believe that our constructors should develop a motor for automobiles adapted for burning the same kind of kerosene that we burn in our lamps. But in France we generally use the burner called Cosmos for our kerosene lamps and it gives a very good illumination, a flame which is quite white and of suitable height and which does not smoke, but it has these qualities only if the wick is fed with kerosene of American origin. This kerosene, so nearly perfect for our lamps, is very easily decomposed under the influence of heat and then deposits carbon and releases lighter hydrocarbons. For this reason its use in motors produces fouling by deposits of lampblack. The kerosenes of Russian, Roumanian or Austrian origin, on the other hand, are not easily decomposed by heat, and if their richness in carbon does not admit of using them unmixed for lighting purposes, they make up for this deficiency by being very suitable for motors, in which they cause little or no carbon deposit. The kerosene to be used for motors should not be the same as that used for lighting. It should not be very homogeneous, either. The grade which produces best results contains a certain percentage of volatile products serving to facilitate the ignition of the explosive mixture.—Georges Girou in *Technique Moderne*, June.

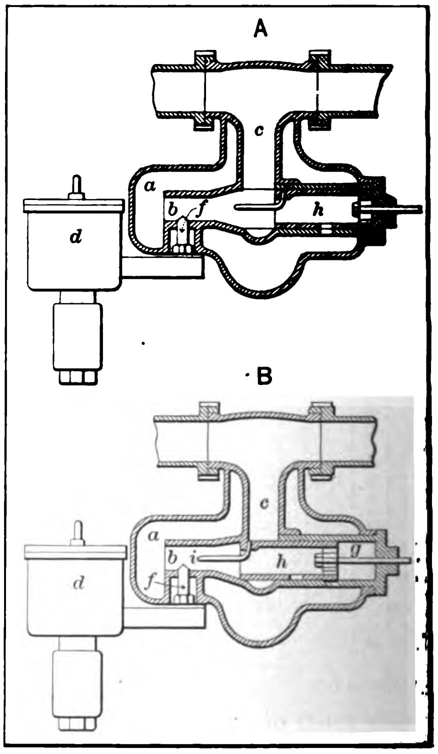

Fig. 1A and B—Carbureter device for minimum motor speed

In a recent article in *La Technique Automobil et Arienne* Mons. Claudel, the designer of the automatic carbureter of the same name, says that, theoretically. the best mixture develops a heat of 2,788 deg. Cent., 1,957 deg. with one and a half times more air, 1,488 deg. with twice and 1,010 deg. with thrice more air.—*Motor Trader.*

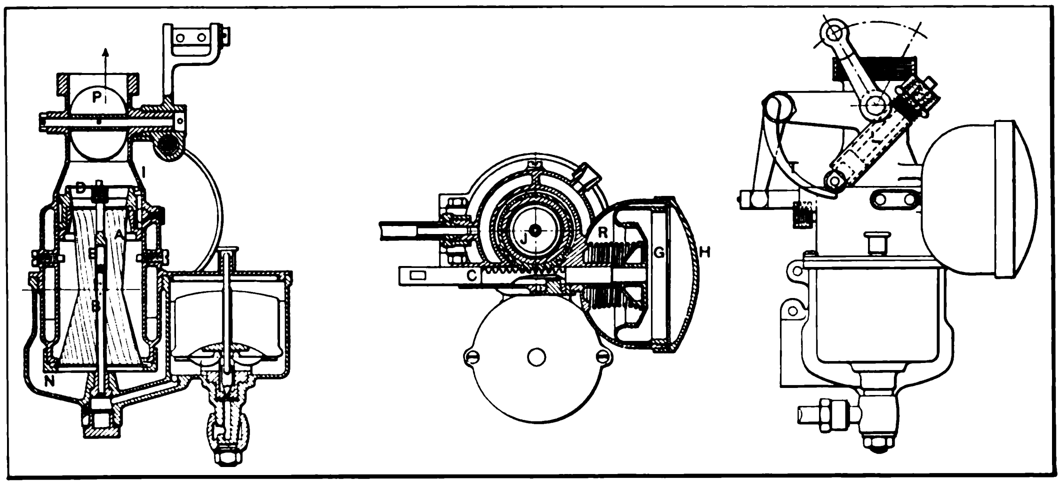

Fig. 2—Rebourg constant-mixture carbureter

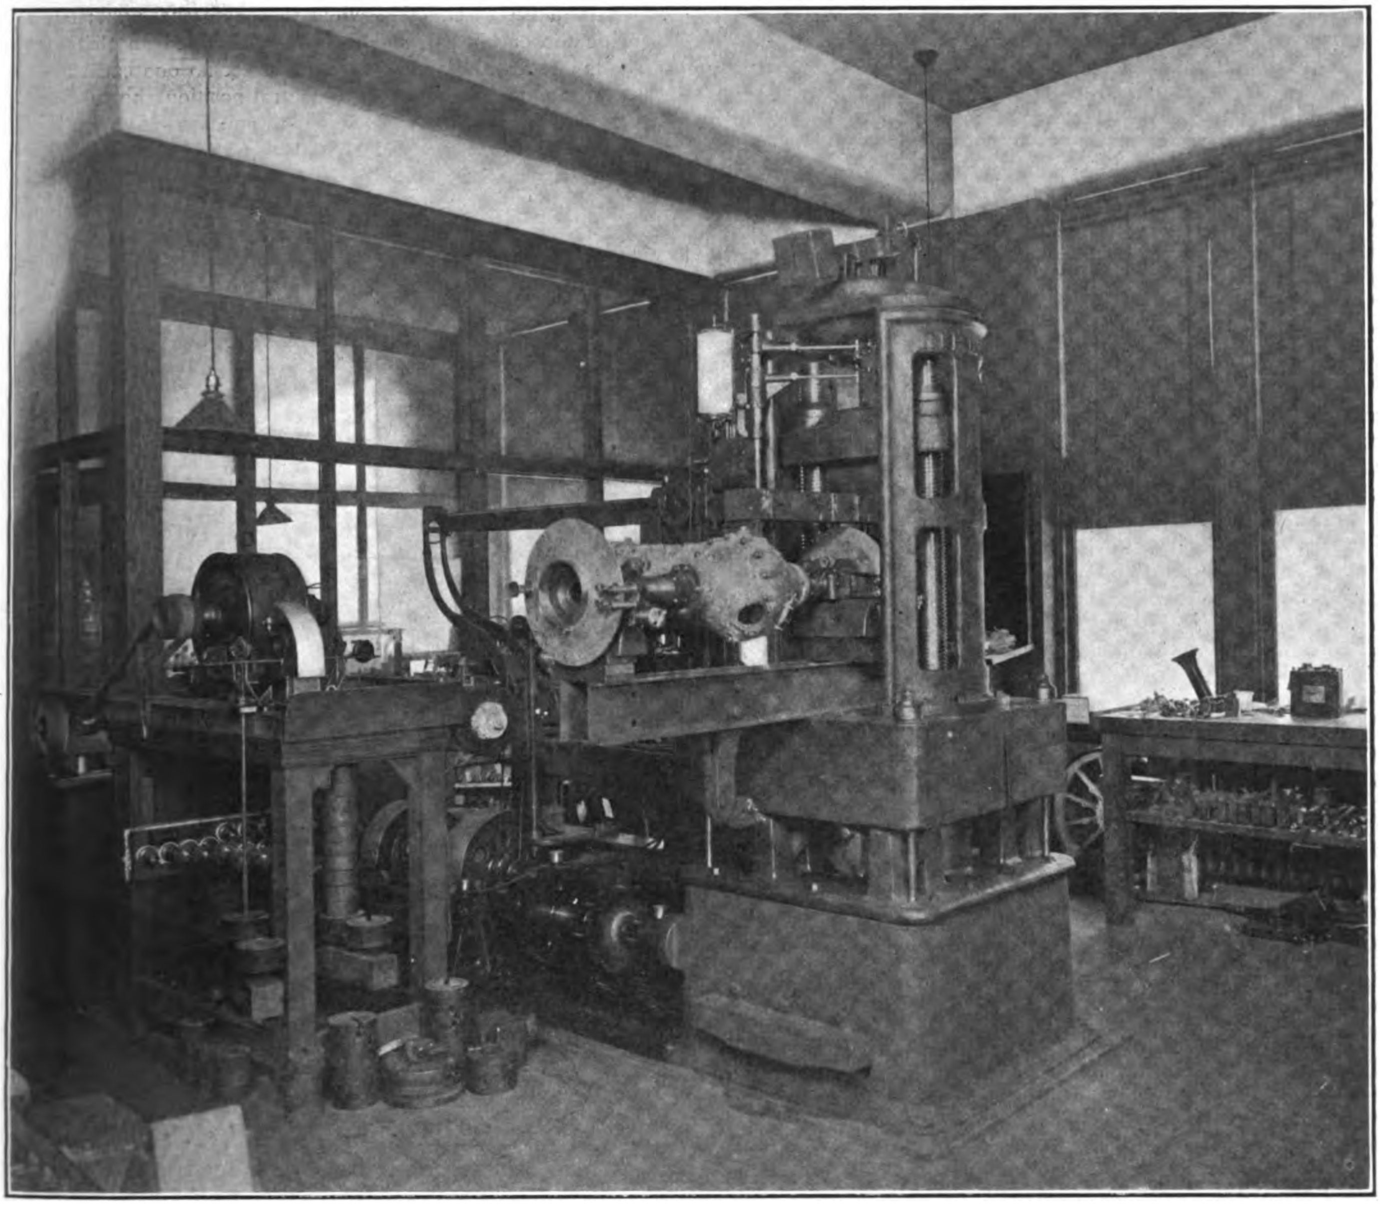
Engineering Section

DEVOTED TO THE DISCUSSION OF ENGINEERING PHASES OF AUTOMOBILING, INCLUDING DESIGNING AND CONSTRUCTION FEATURES OF PRODUCTS, AND INFORMATION TO AUTOISTS



THE LABORATORY IS A BUSY PLACE IN THE PLANT—EXAMPLE OF PACKARD PRACTICE

THE great problem from the point of view of the makers of automobiles, and from an economic point of view as well, thus interesting users of cars, comes in the consideration of what to do with more or less worn-out machines. The second-hand car gets in the way of the maker, to whatever extent it prevents the sale of a new automobile, and it stands in the light of the aspiring automobilist if it prevents him from buying a new car and fails to come up to his requirement, if he elects to invest in a second-hand automobile instead. The maker should have no good ground for complaint, provided the second-hand car is capable of doing useful work, but some method will have to be contrived in the long run by means of which it will be possible to determine when a second-hand car ceases to be of real value.

Every purchaser of a second-hand automobile, whether or not he has had the benefit of prolonged experience, realizes that the major portion of all offerings is far from what he wants. He goes forth contemplating the sweet-running qualities of a new automobile, and he hopes to enjoy these sweet-running qualities in a second-hand car. Admitting that perhaps 90 per cent. of all the second-hand cars to be had are strangers to sweet-running qualities, it remains for the intending purchaser to find what he wants in a grab-bag, as it were. This would be a serious matter for a veteran automobilist to undertake, but when a man who has never had anything to do with a problem such as this figures on coming out whole, he shows evidence of much bravery, with a chance of being called "foolhardy."

When the Owner Drives

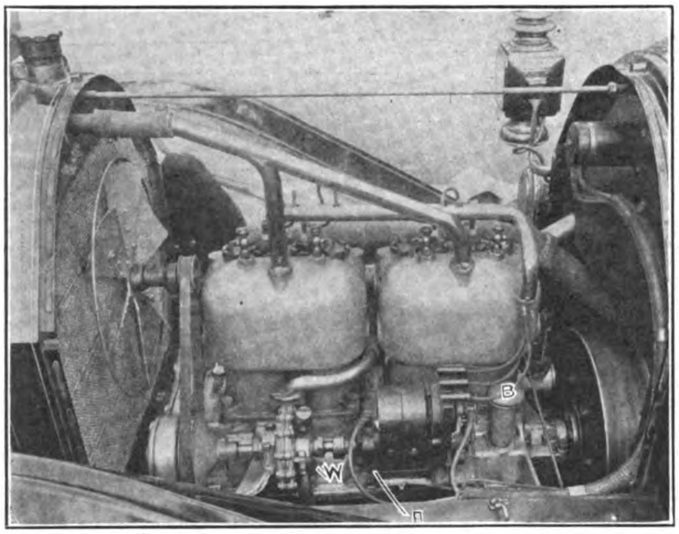


Fig. 1—Left-hand side of the motor, showing pump, magneto, oil level and oil filler cap

AFTER the first principles of the automobile have been mastered—and it is essential that this should be done before the owner thinks of taking the car in hand—he should familiarize himself with the different operations of the car. It is difficult at first to make the hands and feet work simultaneously. Before an attempt is made to start the car the different ingredients, viz., water, oil and gasoline, must be verified. The level of the oil is shown in a glass gauge placed beneath the magneto and marked A in Fig. 1.

The gasoline tank is situated under the front seats and the filler will be found under the passenger seat. To turn on the gasoline lift the floor board and turn on the tap above the gasoline feed pipe. There is also a tap to empty all the gas in the tank, and this should be drained off every 2,000 miles to rid the tank of any impurities that may find their way in.

The tension of the fan belt should always be such that there is no slack. To take up slackness, undo nut C in Fig. 5, lift fan bracket and tighten nut C again.

After these details have been attended to, which does not take more time than it does to read these few words, the needle valve of the carbureter should be raised to flood the carbureter marked D in Fig. 5 and the switch turned to the right; this is placed on the dashboard and has a key, G, fitted so that when the car is left in the garage or in the street no one can start it.

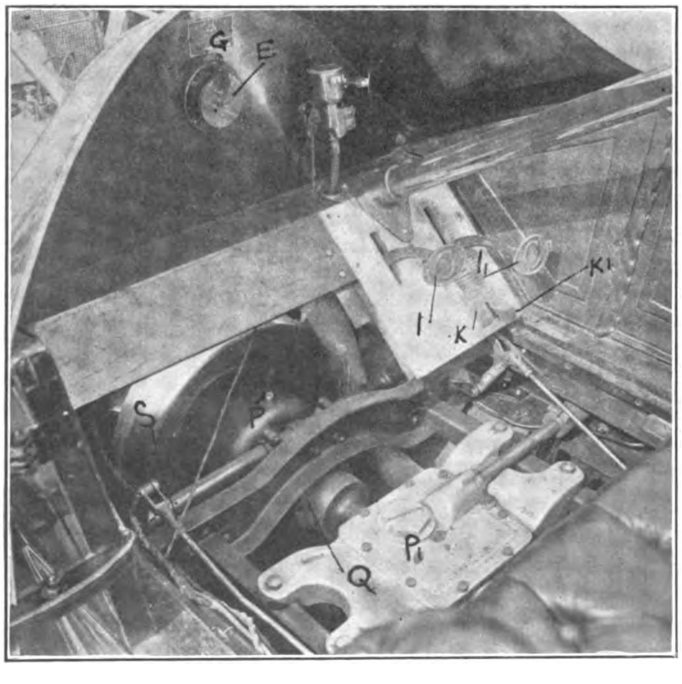

Fig. 2—Showing clutch mechanism, filler plug, switch and locking key, control pedals, gear box suspension and brake adjustment

See that the gear lever is in the neutral position shown in Fig. 6. This can be verified by moving it to and fro sideways. The levers on the steering wheel should then be set for starting. The top lever marked H in Fig. 6 is the ignition lever. This should be set about halfway between the bottom and its position as shown in the illustration. The throttle lever, the lower one marked H_1, should be set about two inches from the bottom.

After the engine has once been started, turn switch over to M, which means magneto; it should be possible to restart it again during the day by turning the switch to the right and pressing button E in the center of the switch marked G.

Fig. 3—Correct position for sitting while driving and method of holding this particular change speed lever

Now take your seat at the wheel, depress the clutch I (Fig. 2) to the full extent of its travel, which is not much, and wait for the primary gear shaft to slow down to engage the first speed, which is done by pressing the lever T sideways toward you and drawing same backwards to position marked L on quadrant—in Fig. 6. The ignition lever H should now be placed as in the position in Fig. 6. By depressing the accelerator pedal K slightly to speed the motor and letting the clutch pedal I up gently the car will move forward. Wait for the clutch to take proper hold before pressing the pedal K down again to increase the speed; to change to second speed release the pressure from the pedal K and declutch; take the gear lever T and push it forward with a slight outward pressure so that when it arrives at the gate it will lay over to the right and the continuation of the forward pressure will make it drop into the second speed, the position on the quadrant being marked M for medium. This operation of changing should be done deliberately and without waiting in the gate; otherwise the engine shaft will have time to slow down and may cause the gears to engage badly. The same operation is to be followed as from first to second speed until a momentum

HOW TO MANAGE A CARHARTT CAR, WITH INSTRUCTIONS AS TO LUBRICATION, TIMING, CARBURETION, AND COOLING

of ten to twelve miles per hour has been attained. To change to third or high gear, take the gear lever in the hand, ready to pull back to its full extent, but do not press the clutch more than half its travel; otherwise the dogs of the high gear will not mesh easily. If the lever does not move easily through quadrant and across the gate oil at O, Fig. 6. This requires frequent oiling, as dust gets into it.

After the car has attained a speed of, say, twenty miles per hour move the spark lever H three parts the way up the quadrant and then it requires very little touching.

To change from high to second speed care should be taken that the speed of the engine shaft is not allowed to drop too low, and after the clutch is released the lever should be pushed forward as far as it will go, to M, quickly. The same applies to changing from second to low.

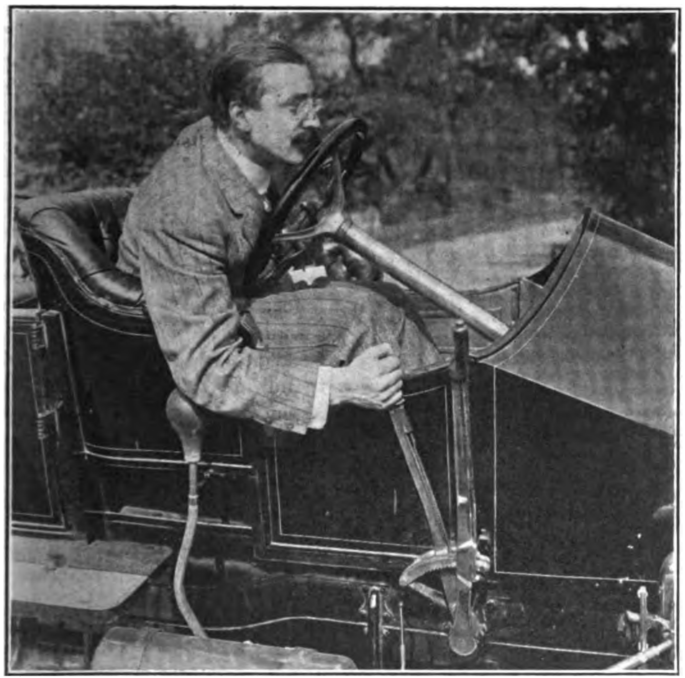

Fig. 4—This position may look racy, but is very tiring and perfect control over the pedals and wheel is lost. Note wrong way of holding knob type lever

The brake, which is operated by the pedal I, in Fig. 2, is powerful and if properly adjusted is sufficient to hold the car under any conditions. The handbrake is conveniently situated (T, Fig. 6) and should be used on hills and in gently slowing up, so as not to give the footbrake too much work and to accustom one's self to using it when an emergency necessitates a quick stop.

The throttle lever H_1 should be left in such a position that the engine just turns over when the clutch pedal is depressed.

To drain the water undo the plug under the radiator; also the tap W (Fig. 1.) If this is not done some water will remain in the pump, and if it freezes a broken pump spindle will be the result. The greaser on the pump should be given a turn every day. To remove the magneto undo four holding-down bolts under the bed plate, but first mark the dog-clutch coupling.

The air valve A_1, Fig. 5, needs cleaning from time to time. Do this by pouring a little gasoline on it and turn it round on its seat by the adjusting nut. Slackness in the steering can be taken up by giving a slight turn to nut X. Undo nut Z to lubricate the steering box. To release the inlet manifold undo nuts B_1.

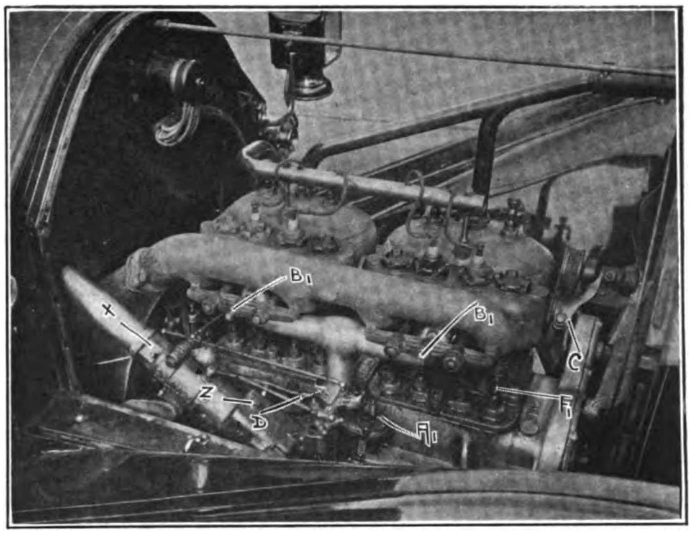

Fig. 5—Intake side of motor, showing carbureter, steering adjustment, fan belt, tightening nut and adjusters for valves

When the valves are worn the distance between the lifters and valve stems can be regulated by adjusting nuts F_1, so that a visiting card will just slide between the two surfaces.

Fig. 3 shows how to sit at the wheel and change speed and Fig. 4 how not to do it. There is no necessity to move from the comfortable position shown in Fig. 3. The gear lever should be taken in the hand as indicated so that when you want to use the reverse the index finger is ready to press the knob T_2. If the position in Fig. 4 is followed command of the steering is lost.

The clutch fork Q, Fig. 2, under curved chassis member needs lubricating every day. P is a plug on the plate clutch boss. Undo this every week and insert a mixture of one-third kerosene and two-thirds lubricating oil.

K_1 is the exhaust cut-out pedal, to operate which press down till it catches in a notch; to release, press it upward with the toe of the right shoe.

To fill gear box with oil the cap P_1 should be undone. Behind the gear box a ring with a milled edge will be found to lubricate the universal joint and this requires frequent filling with grease; unscrew the ring and the special cap will slide back.

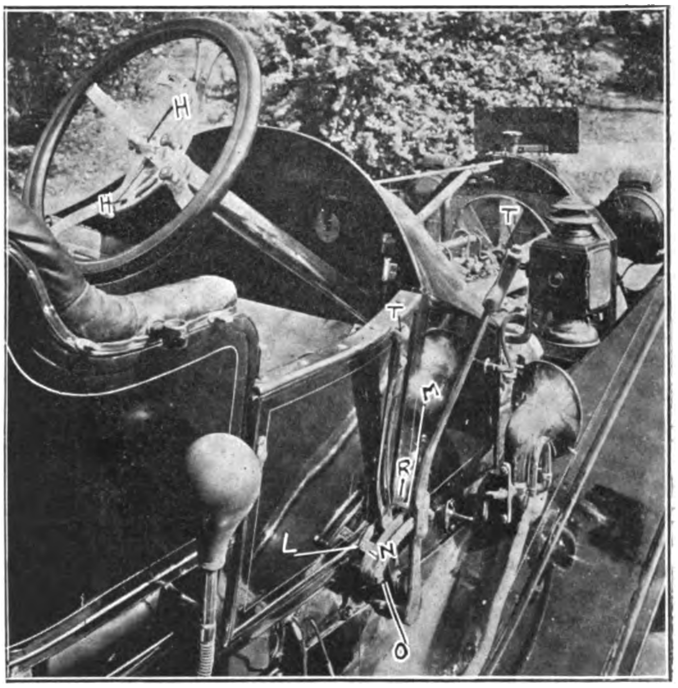

Fig. 6—Control levers on steering for ignition and throttle gear and brake

Injunctions.

Don't decide before you see the car whether or not you will like it; the wish should not be father to the thought.

Don't look with a prejudiced eye; you might as well not look at all if you refuse to see.

Don't let some other pair of eyes do the looking for you; what is the matter with your own? Moreover, the other eyes might be near-sighted.

Don't look at the paint on the body while you are thinking of the carbureter.

Don't examine the striping on the wheels while you are wondering whether or not a magneto is used in the ignition system.

Don't become fascinated with the brightness of the lamps and forget to observe the method of lubricating.

Don't spend all your time admiring the straight lines of the body; the cooling system remains to be looked at.

Don't go hunting around for a place to put your baggage until you find the place where the tools are stored.

Don't just glance at the place where the tools are supposed to be; count them; give a thought to the character of them; a bundle of wire is worth about a nickel; credit the "kit" with all that it has in its make-up, but no more.

Don't try to figure out where the spare tire is to be stored on the car; let the maker of the car dispose of such details for you.

Don't assume that the lubricating oil can be carried in your hand; let the maker of the car provide a place for it.

Don't usurp the position of designer of the automobile that attracts your notice; buy a car that has been designed.

Don't assume that a car that looks bad is good. True, beauty is as beauty does; equally true, beauty is an outward sign of an orderly interior.

Don't fool with the carbureter and after you put it out of joint assume that it is no good; the chances are that it is as bad as you make it; the equal chances are that any other carbureter will be in the same fix after you get through tinkering with it.

Don't expect to go too far on a gallon of gasoline; some of the distances covered (theoretically) on this amount of fuel are past practical mention.

Don't start out with a little lubricating oil; have as much as there is storage room for; it is marvelous how much damage that can result from the absence of lubricant for just five minutes.

Don't fall in love with the magneto to the extent of neglecting the battery ignition; an old friend comes handy in a pinch.

Don't expect a battery to be in good working order after it has stood in idleness for a year and a day; it may be a wizened old man incapable of active service when you get to it.

Don't neglect the wiring; it should be examined at regular intervals; poor joints offer a high electrical resistance and defeat service.

Don't assume that the wiring is perfect simply because the joints are in good order; there may be a fault in the wire under the insulation at some point; feel along the insulation until you come to a spot that indicates lack of continuity, just as a doctor examines for a fractured bone in the arm.

Don't neglect the contacts in the magneto and timer; they have to stand a large amount of rubbing and in time the effect is to wear them out; replace them at the right time.

Don't allow grease to remain on the surfaces of the insulation of the wiring; grease and rubber, of which the insulation is made, are far from good friends; unfortunately, grease gets the better of the argument.

Don't, under any circumstances, fail to grease all the little joints around the chassis; grease is the keeper of the bearings.

Don't allow mud to dispossess the grease that is placed to lubricate and protect the bearings; if the grease is present in quantity sufficient to fill the space mud cannot get in.

Hints on Care of Tires

After four years' experience I am confident that the solution of the automobile tire problem will not be found in discarding the pneumatic tire for some other kind, but in selecting the best pneumatic on the market and giving it proper use and care.

When an owner finds that two sets of tires do not give the same amount of wear, he frequently concludes there is defective material or workmanship in that make of tires, forgetting that conditions of service vary so widely, and that drivers are often heedless about starting suddenly, and careless about the many little things that seem insignificant to them, but which affect tremendously the life of his tires. The service received depends as much on the proper care as on the quality of the rubber and workmanship.

Observe carefully the different automobiles you pass and you will notice that a large percentage of tires are used without being properly inflated. Ask the driver, whose tires disintegrate rapidly, and who is constantly complaining about blow-outs, if he keeps his tires as highly inflated as the manufacturers request and invariably he replies, "No." Usually he has no knowledge as to the amount of air his tires contain.

Often the driver never thinks of his tires until he observes they are nearly flat; or else he is ignorant of the fact that when a tire is imperfectly inflated the walls bend back and forth, with the same result as when you bend a piece of wire back and forth in your hands; it weakens and breaks. Few tires are strong enough to stand the heat engendered in the threads, the weight of the car, combined with the air pressure and gross carelessness. The most remarkable thing about the pneumatic tires is that they last so long in view of the ill-use and improper care they so often receive.

If drivers would be sure that their tires are properly inflated before starting they would find that rim cutting, which is caused by the play between the rubber and metal of the wheel, would seldom occur before they are fully satisfied with the mileage received. Remember you cannot always tell from appearances whether or not your tires are perfectly inflated. A good gauge should be secured, and then it will be the exception when a good tire will not travel five thousand miles.

Another improper use to which pneumatic tires are put is constant overloading. Every car should be carefully weighed and the equipment and load carefully considered, in order that the driver may have a margin of safety and not carry more than the tires were made to stand.

You do not expect your boy to do as much work as you do because he does not possess your strength; neither should you be so unfair as to insist that your tires shall do more work than their strength warrants.

Again, owners are careless about tire shoes when the car is in the garage. Often the car will not be used for long periods of time. Instead of jacking up the car and taking the weight off the tires and partially deflating them, they stand just as the car was placed when the last trip ended. This exerts a continual and unnecessary strain on the walls of the shoe.

But if time is taken to jack up the car and partially deflate the tires the life of the shoes will be materially lengthened; as then they will be called upon to bear only the pressure of the air with which they are inflated. This is slight compared to the strain they must bear when they support the weight of the car. And if one will follow this course the life of the tires will be increased by about one-half the time the car stands idle.

Care should be taken that the car does not stand with deflated tires without being jacked up. Watch carefully that the tires

REV. PERCY R. FERRIS SAYS: "SOLUTION OF THE PROBLEM DOES NOT LIE IN DISCARDING OF PNEUMATICS; SELECT THE BEST AND GIVE THEM CARE"

do not stand in oil or grease and wipe off any oil that may drop on the tires. Oil greatly softens rubber and takes away its resistance and elasticity.

In cold weather, if it is desired to lay up the car, the tires should be removed from the wheels and after carefully wiping off all oil or water wrap them up in a soft cotton cloth to keep out the light; then put them where the temperature will be moderate. If you leave your tires in the direct rays of the sun, or in a very warm place, the rubber will quickly lose its elasticity and become hard and cracked. A few months of such treatment will destroy the life of the best tires.

Be careful in driving your car for the sake of your tires if for no other reason! Careless driving causes more harm to tires than we dream of. Start your car gently and with your mind on what you are doing. Take every corner at a moderate pace and do not stop suddenly unless unavoidable. When curves are taken at high speed the strain on the sides of the tires is detrimental. Carry tire chains for wet roads to prevent skidding, which is a very dangerous experience to tire, car and driver.

In driving up to a curb never let your wheels rub against the curbing as you come to a stop, for it will wear out the rubber at the thin point of contact and is liable to bend the rim and pinch the shoulder of the shoe. If possible to prevent it, do not permit your car to run in a rut, as it is liable to greatly injure the tires; and never apply your brakes suddenly unless forced to do so by some emergency, because when the wheels cease rotating before the car stops the tires drag and wear tremendously.

Examine your tires at frequent intervals for cuts, which as soon as found should be washed out with gasoline and rubber cement or plastic put in the gash. Then bind with tape and leave it wrapped with the tape until the car is to be used again. At the first opportunity the cut should be vulcanized to prevent mud-boils and sand-blisters. The maker is the proper one to repair the tires, as it is to his interest to see that the work is well done.

Just as soon as the fabric is exposed the shoe should be sent to the factory, if the owner desires to preserve the fabric, and present permanent injury. When proper care is given, and the tires are not weakened by bending or by extra strains, the fabric should retain its strength indefinitely. But let the moisture penetrate the tire and at once the fabric begins to disintegrate and lose its power of resistance. As long as the fabric can be preserved blow-outs will not occur, though it tears comparatively easy once it is cut or injured. Kept in proper condition it will resist severe strains for a long time.

Remember the wheels of every car should be examined occasionally to see that they run parallel to each other in order that the tires may not be subjected to a grinding action which wears out the tread rapidly. Look over the rims at frequent intervals to detect dents or rust. It is quite easy to dent some rims and often the edges wear down to such a sharp edge that rim cuts result.

Just a word about the care of extra casings. It is so much easier to change tires in case of trouble than to repair old ones that few owners drive without carrying the extra shoe.

It is the part of wisdom to change your tires from left to right and vice versa at least once a year to distribute the wear as evenly as possible. Place good covers over your casings and secure them on the car so that there is no danger of chafing. Put the cover over them so carefully that no water can enter.

And when you place your tubes in the shoes sprinkle plenty of soapstone within, so that friction may be reduced between the casing and the tube, and the heat which is so often generated by this friction prevented.

Instructions.

When the carbureter becomes unruly the difficulty may be:

(a) Nozzle too large.
(b) Nozzle too restricted.
(c) Needle in nozzle not properly set.
(d) Depression too low.
(e) Depression too high.
(f) Too little initial air.
(g) Too much initial air.
(h) Too much auxiliary air.
(i) Too little auxiliary air.
(j) Float too high.
(k) Float too low.
(l) Passageways stopped up.
(m) Air locked.
(n) Pocket of water.
(o) Float punctured.
(p) Mechanical interferences.
(q) Leak around manifold flanging.
(r) Adjustment awry.
(s) Filter stopped up.
(t) Low pressure.
(u) Control system awry.
(v) Carbureter too small.
(w) Carbureter too large.
(x) Manifold not right.
(y) Poor gasoline.
(z) Gasoline not turned on.

Remedies for A to Z Carbureter Troubles—

(a) Fit smaller jet or solder up orifice and redrill.
(b) Use taper reamer.
(c) Adjust till correct position is found.
(d) Fit lead washer beneath jet base.
(e) File top of jet or better reset needle valve.
(f) Drill a few additional holes at convenient places.
(g) Fit shutter, locked by a set screw.
(h) Increase tension on spring or block up ports.
(i) Decrease tension of spring, enlarge slot and ports.
(j) Unsolder balance weight holder ring, lower same on needle and solder or weight down float equally with a little solder.
(k) Unsolder balance weight holder ring and raise same.
(l) Unscrew same and clean them, using air pressure (tire pump); don't use pins in the jet.
(m) Unscrew gasoline pipe from carbureter and allow gas to flow through, look to stoppage in hole of filler cap in gravity-fed cars.
(n) Same as (l).
(o) Drill another small hole, blow or boil gasoline out and solder.
(p) Disconnect carbureter entirely, thoroughly clean out, verify everything, and if it does not then work have some one put it in order that understands how to.
(q) Replace old joint by a new one; if you haven't a new one make one from stout brown paper and boiled oil or white lead.
(r) Readjust but leave jet alone; if it ran all right once it will do so again unless the motor is worn badly.
(s) Disconnect and clean out; should be cleaned once a month.
(t) Clean pressure valve and go over all connections, copper pipes sometimes split at the seam.
(u) Readjust and tighten up, or if worn take up play.
(v) Fit larger carbureter.
(w) Try adjusting jet and closing ordinary air intake; if it will not work, fit smaller carbureter.
(x) Consult makers of car or engine and have a new one made, patched induction pipes do not work well.
(y) Empty out every drain of old gasoline anl pay more money and get better quality, or if the dealer has only one quality go to another dealer, or better still, buy direct and store it yourself if you have the convenience.
(z) Turn it on.

Order of Six-Cylinder Firing

Editor The Automobile:

[2,398]—I am a subscriber for years. Please inform me how a six-cylinder motor should fire. I have one that fires 1-3-5-6-4-2.

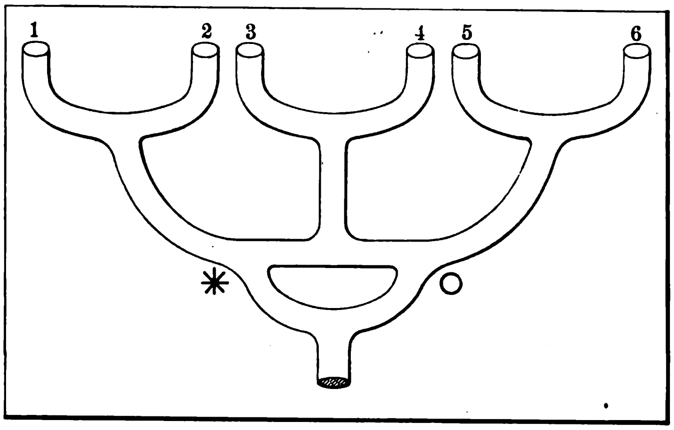

Fig. 1—Showing one type of six-cylinder induction pipe

A mechanic claims it should fire 1-4-2-6-3-5, as the gas can be gotten to the cylinders with more uniformity. The intake is designed so as to have 1 and 2 draw together, 3 and 4 together and 5 and 6 together. When this auto is on a State road going 25 to 30 miles, it runs smooth and good, but when on rough roads going slow the cylinders fire irregular and bother. Another claims faulty construction of intake manifold (Fig. 1).

Is it best and of proper design? If not please give me information to have a better one made. I do not mention maker's name. If you can assist me please inform me. The auto is very satisfactory, but engine, six-cylinder 4½ x 5 geared 3½:1, does not give good results; weight 2,800 pounds. It does not do near as well as my four-cylinder, 4½ x 5¼; weight 2,950 pounds.

Forgot to state that a duplicate of this six-cylinder. in a boat, was helped by closing the pipe marked O and drawing supply through place marked * (Fig. 1).

Can you assist me?

Syracuse, N. Y. **Edwards.**

Without knowing the make of car it is impossible to tell you the firing order, as the following table will show that different makes of six-cylinder engines fire differently. Perhaps you will find your engine in the list:

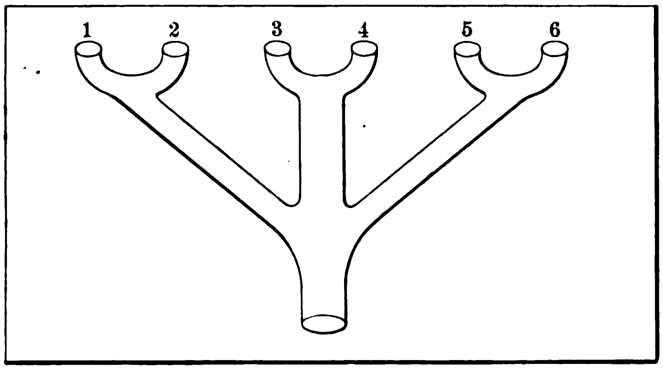

Fig. 2—Suggested alteration in shape of induction pipe

Pierce-Arrow	fires	1-5-3-6-2-4
Winton	"	1-5-3-6-2-4
Lozier	"	1-2-3-6-5-4
Peerless	"	1-3-2-6-4-5
Matheson	"	1-4-2-6-3-5
Stevens-Duryea	"	1-4-2-6-3-5
Knox	"	1-5-3-6-2-4
Alco	"	1-4-2-6-3-5
Thomas (K)	"	1-4-2-6-3-5
" (L)	"	1-3-5-6-4-2
Franklin	"	1-4-2-6-3-5

It will be seen that there is only one engine that fires in the sequence that you give.

With regard to the induction pipe this appears too complicated, besides having too many elbows against which the rush of gas has a chance of condensing before reaching the cylinders.

The shape of induction pipes is dependent on the sequence of firing, and is more a matter of trial and error than actual theory. The majority of six-cylinder motors have their cylinders cast in pairs with only three ports to feed, and it is then a very simple matter. The method shown in Fig. 2 is a suggestion that might suit your engine, but without more data we cannot recommend it as being a sure cure for your troubles.

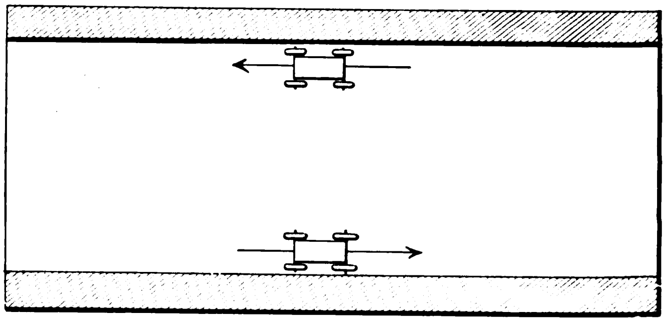

Fig. 3—Slow moving freight automobiles passing each other, both keeping to the right in order not to obstruct the positions that belong to quick moving automobiles

Wanted: A Disinterested Party

Editor The Automobile:

[2,399]—Am now trying to decide which car (Roadster type) to buy and was very much interested in your "dont's" of last week. They really do not help an inexperienced buyer very much in selecting the best car for the money. Could you refer me to some disinterested person to whom I can apply for advice and have him answer a couple of questions like these: "What car costing under $1,000 or $1,200 in your judgment would give me best service (Roadster)?" Also: "What car costing less than $1,500, etc.?" and have him tell me why. Whether this scheme would work I do not know, but would like your opinion. Would be willing to pay a reasonable price for the advice, of course. Thanking you in advance, I am, yours very respectfully,

Wm. Ryan.

Muskogee, Okla.

With reference to your esteemed favor of the 5th inst., we think that you will have a difficulty in finding a disinterested party to advise you. We are glad you are interested in the "Don'ts" that appear in The Automobile, but the choice of the car is dependent upon certain local conditions and the work that you intend to put the car to.

You can find several people who will give you advice upon a second-hand car as to its wear and value, but with a new car the case is not the same.

Personal demonstrations and opinions of users of the car are the best criterion.

Starting a Car Without a Crank

Editor The Automobile:

[2,400]—Is it possible to start a car if the starting handle has been damaged or lost?

Endeavoring to turn the motor by the flywheel is a very dangerous operation and should not be resorted to. If there is any one else in the car put the car in the high gear, inject a small quantity of gasoline in the cylinders and let the car be pushed with the clutch out. After a little momentum has been attained let the clutch in softly and the engine should start even on magneto. If alone, however, jack up the rear wheel, put in the high gear and turn in the forward direction.

H. W. M.

Trenton, N. J.

Slow Moving Automobiles to the Side of the Road

Editor The Automobile:

[2,401]—Is there any law that makes it mandatory for slow-moving automobiles to get out of the way of speeding cars?

H. L. S.

New York City.

Questions such as this are handled under the head of "police regulations," and the police power of the respective States is sufficient for the purpose. If the police are instructed in accordance with the spirit of city ordinances, and have among their instructions those which require them to so regulate traffic that freight automobiles are directed to keep to the sides of the street, for the purpose of making way for the faster passenger automobiles, it may be regarded as well within the law. Figs. 3 and 4 show the right positions for freight and passenger automobiles under such conditions, it being assumed that the freight automobiles will be slow moving, relative to the speed of passenger automobiles, but it will be understood, however, that passenger automobiles are not given the right to violate the fundamental speed laws simply because they are given the right of way.

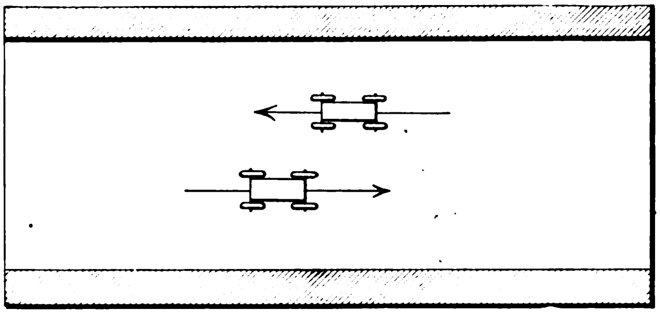

Fig. 4—Quick moving passenger automobiles passing each other, occupying a center position in the street, leaving room for slow moving automobiles at the sides of the street

Moving Wire Not Necessary

Editor The Automobile:

[2,402]—I am much interested in magneto ignition work, and would like to have you state whether or not it is necessary to employ armatures with moving wire, provided some means is utilized for varying the magnetism.

Erie, Pa. C. R. S.

An electromotive force will be induced into the wire whether or not the same is placed upon the rotor, provided the magnetic fluxes vary. Flux variations may be brought about by making and breaking the magnetic circuit. This is a mere matter of utilizing the rotor, one form of which is shown in Fig. 5. In this example, the coils of wire are placed on cores formed out of the polar horns. The cores are in the path of the magnetic flux, and the magnetic circuit is interrupted by the rotor, due to its shape. This form of magneto will be highly efficient if the general design is properly looked after, provided the permanent magnets of the magneto are made of a proper grade of tungsten steel, and are suitably magnetized for the purpose.

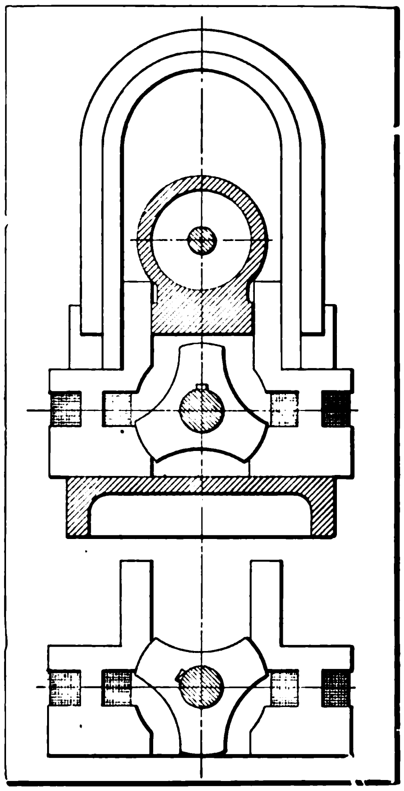

Fig. 5—Cross-section of a rotor type of magneto with fixed coils embedded in the soft pole pieces, eliminating the use of wire on the moving parts

As to the Use of the Pyrometer

Editor The Automobile:

[2,403]—What is the best way to use the pyrometer in connection with furnaces? O. J. M.

White Plains, N. Y.

The illustration Fig. 6 as here given will be sufficiently clear to require no further explanation, unless to point out that the measuring instrument is very delicate, and should be placed in a well lighted room so that the observer will be able to note the readings with precision. Attention should be given to the means at hand for maintaining the proper temperature of the cold end.

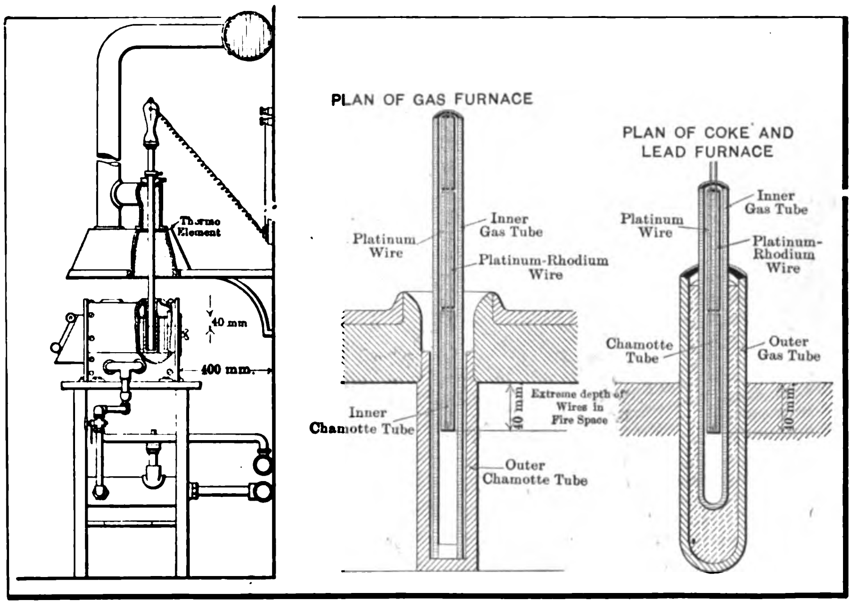

Fig. 6—Illustrating the installation of pyrometers in gas furnaces for heat treatment work

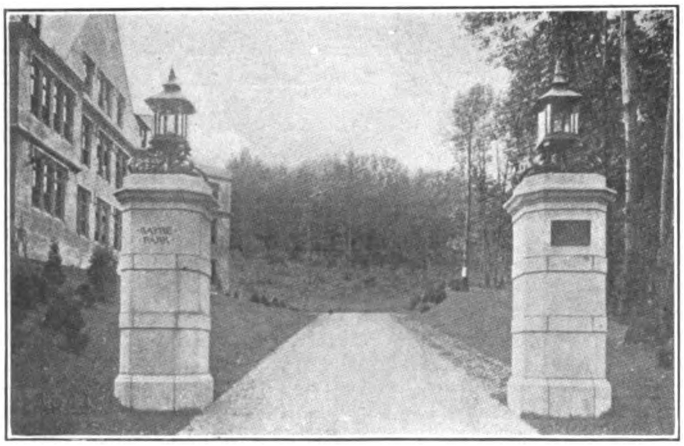
Touring in a Runabout

JAMES S. MADISON RELATES SOME EXPERIENCES WHILE TOURING IN A RUNABOUT THAT ARE PLEASANT TO READ AND INSTRUCTIVE AS WELL

THE average runabout of small wheels and light weight is not intended for touring purposes and is poorly adapted to such use. No matter how ambitious the owner of such a car may be or how much confidence he may have in his car he should be rather wary about attempting a tour unless he is entirely willing to take chances and meet his trouble philosophically when it comes. The most serious objections to all the popular runabouts are their short wheelbase, light weight, small wheels and consequently small tires. Each of these factors helps to render them unsuited for long trips over all conditions—good, bad and indifferent—of roadbed. The total combined effect is to transmit a very large proportion of all road shocks, from whatever cause, to the power-plant, transmission, body of the car and to the passengers. Under these conditions touring more nearly approaches a torture than a pleasure. The storage space on a runabout is also limited to a very small amount so that one cannot take with him the necessary spare parts for emergencies, or suitable wearing apparel.

It should always be remembered that the runabout, as its name implies, is intended for town use, and for such portions of the country as have advanced to the point of good roads. I have in mind a popular 20-horsepower, four-cylinder runabout that on the splendid, level, oiled roads of eastern New Jersey would give most excellent satisfaction as a touring car. But if this same car were used for the same purpose in the western part of the State or on the average roads of Maryland or Pennsylvania the result would be disastrous. There are, however, runabouts that may be used with great satisfaction for long tours. In the writer's judgment the necessary requirements are these: The wheels should be at least 30 inches in diameter, the tires should be large, not less than 3½ inches in diameter—a 4-inch tire would be better—the car should be provided with excellent springs—springs that are merely "good springs" will not answer—and it must be sturdily built throughout. It ought to weigh not less than 1,400-1,600 pounds, and have an engine capable of developing 15 to 18 horsepower at the wheels. There must also be plenty of storage space. With a car of this type one may take tours of any desired length with but very little trouble.

Following is an account of one of many trips the writer has taken. The car is equipped with unusually large tires, 31 x 4 in.; for this reason partly and also partly because the car is usually not driven faster than 16 miles an hour there has been remarkably little tire trouble—two punctures and one blow-out in 7,500 miles. On this account it has not seemed necessary to be bothered with carrying a spare casing. A blow-out sleeve and two extra inner tubes have answered perfectly all demands up to the present.



Entrance to Sayre Park, Lehigh University, South Bethlehem, Pa.

A June Trip from the Delaware to Gettysburg

The party consisting of one and one other started from Easton, Pa., in a two-cylinder, air-cooled, fifteen (manufacturer's rating twenty, by A. L. A. M.) horsepower runabout, provided with a commodious rear box, in which were stored chains, curtains, spare parts and our personal belongings. Instead of placing these in the usual suit case, they were wrapped in a linen folder about five feet long by three feet wide, containing a number of pockets of different sizes for various articles, combs, brushes, cuffs, etc. We expected to be gone three or four days and our requirements were strictly limited to the articles absolutely necessary for that length of time. One of the indispensables was an eye-cup and bottle of eye-wash. The writer always finds after a day's run in the sunlight, over dusty roads, with the constantly changing focus of the eyes on the road, that they become inflamed and uncomfortable. The eye-cup and wash bring much relief.

The day was June 29; the sky was clear, the temperature 68 degrees. The first stop was made at Bethlehem after an exhilarating run of seventeen miles over a fine State road oiled all the way. At the corner of Broad and New streets, Bethlehem, we turned to the left (south) on New street, followed it across the Lehigh River (excellent view of the enormous plant of the Bethlehem Steel Co. from the bridge) into South Bethlehem. Continuing straight ahead for about one-third mile we entered the beautiful campus of Lehigh University. The roads inside the grounds are of the most approved macadam construction. All of them lead to Sayre Park, a vast tract of wild, but most beautiful mountain land that the university has cared for so successfully that it is one of the show places of eastern Pennsylvania. A perfect macadam road of about a mile and half in length goes right through the heart of it, affording at many places a view of a magnificent panorama extending for thirty miles or more. The tourist going through Bethlehem who fails to take in this side trip of about five miles in all is missing a rare opportunity.

Spectators congregate to see the trouble

From Bethlehem we ran on to Allentown over five miles of oiled macadam. The next stop was Reading, thirty-seven miles from Allentown, over a road that was fair dirt for much of the way, and good pike the remainder; the last five miles of it was of the same quality as the glistening white sand roads of New Jersey. On approaching the city we saw the now famous sign painted on a large white square board surface: "Automobilists Speak Well of Reading. May We Speak Well of You?" We drove to the square in the center of the town, where we had a light luncheon in a department store—a plan we followed wherever possible. We found the food satisfactory and the expense lower than at the usual restaurant.

During the afternoon we ran on to Lancaster, thirty-six miles, good road most of the way, and then on to Columbia, ten miles farther. Here I made the first mistake in deciding to spend the night. The town is not attractive and the accommodations poor. It would be much better to go on to York—fourteen miles farther.

At Adamstown, a small village between Lancaster and Columbia, it was necessary to take on gasoline. After fifteen minutes' diligent search, a man was found who had some. He filled a four-gallon can by means of a quart measure; the can, measure and funnel were originally tinned, but long use and exposure had obliterated every sign of tin and left only a coating of iron rust. Since the oval funnel with gauze screen which had been purchased especially for such occasions had been forgotten, a handkerchief was used for a filter and the gasoline poured through that—a wise precaution, for there was about a quarter teaspoonful of sediment caught.

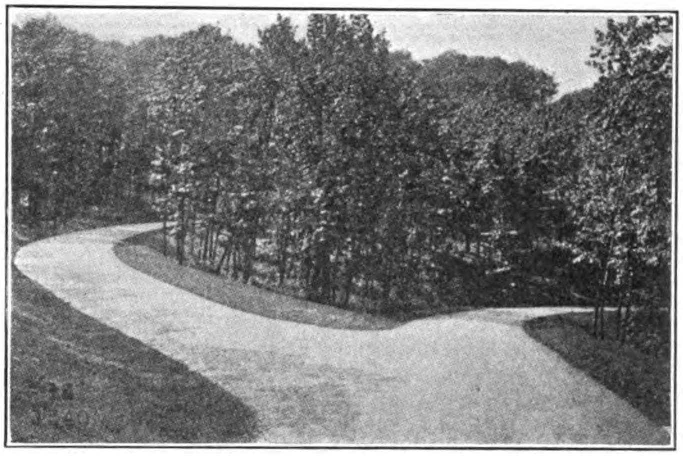
A little oil to keep things going

On the morning of June 30 we left Columbia, passing through York and arriving at Gettysburg about noon, a run of fifty-two miles. The road up to the last ten miles was good, but that is the worst road in eastern Pennsylvania. The average driver's remarks about that particular piece of deviltry are unprintable. I must content myself by saying that it is a disgrace to any civilized community. The fact that it is a toll road and one is obliged to pay for the privilege of going over it makes the imposition all the more shameful.

We spent the afternoon in Gettysburg seeing as much of the battlefield and of the National Cemetery as possible. In spite of the magnet that draws over a hundred thousand visitors there every season, Gettysburg is not a pleasant place to visit. It is a provincial community whose principal industry is taking care indifferently of the strangers who want to know about the battle fought there forty-seven years ago.

The hotel at which we stopped was so burdened with flies that each guest in the dining room was supplied with a fan to keep them off the food and out of his mouth. The waiters, when not busy, stood back of one's chair and aided in keeping the pests at a safe distance.

We left early next morning (having been awakened by squealing pigs and crowing chickens) with great enthusiasm for the thirty-eight mile run to Harrisburg. For twenty-eight miles this road out of Gettysburg was also very bad. Water bars, deep ruts, rough surface, loose stones, etc., tell the unpleasant tale. When within ten miles of Harrisburg the signs became encouraging—we knew we were getting out of the backwoods into civilization. The last lap to Harrisburg was delightful. The city itself is most attractive, with many miles of modern streets and many beautiful parks. From this point we ran on to Warnersville, where we spent the night, forty-four miles over what was at one time a fine pike. At present it is badly worn in spots. The method of repairing the roads is a senseless one, although it seems to be general in Pennsylvania towns and counties. When a soft spot appears in the surface, it is allowed to go until it becomes a hole or rut and it is then closed up by dumping broken limestone in it; the passing vehicles are expected to crush it—and they do, except what they scatter to the side and ahead. This sort of repairing is primitive and and stupid, and also exasperating to the man who is trying to make a set of tires guaranteed for 3,500 miles give him that mileage. The next morning we ran to Reading, ten miles; from there we followed the same route by which we came back to Easton. The total mileage for the entire trip was 311; the gasoline consumed, 24 gallons; the total expense was $35. Of this amount $2.65 was paid for toll, most of it in small sums. The toll gates in Pennsylvania are a relic of the dark ages. They are a great nuisance to the motorist; not the matter of the expense, but the frequent stopping. Many times one has to wait for a woman to leave her washtub or other household duties to come for the toll. As a general principle I should say it would be decidedly more economical and certainly more satisfactory for the average tourist to avoid Pennsylvania, and take out a yearly license in New Jersey. The cost of the toll will almost pay the annual fee, and I calculate that the damage to tires will be about ten times greater in Pennsylvania than in New Jersey. Upon examining the tires after returning, the tread of each casing was found to be hopelessly cut up by the loose stones, and while all the casings were old, having been driven 4,400 miles, it was evident that nothing would save them except a retread for each at a cost of $14 apiece.



The Junction, Sayre Park, South Bethlehem, Pa.

A Word of Advice as to Tires

Concerning tires, have the best that money can buy, and by this it does not necessarily mean the dearest; but a tire that has given good results to others should give the same to you if you treat them properly. It is better in the long run to have a larger size tire fitted to the car even at an extra cost than to run on tires that are overburdened, and in this particular communicate with several tire companies and find out what they consider the correct size should be for a given weight, and while speaking about weight insist upon a specific weight being given you by the maker of a car and not "Oh! about so and so many pounds." Sometimes through lack of knowledge and sometimes through desire to make the weight appear as small as possible the question is evaded in this manner. You can get anything in the way of information if you insist.

Salesman Made a Grave Mistake

Purchaser: "Say, man, there is a mistake in this bill."

Salesman: "Oh, no! You are quite mistaken, the bill is right."

Purchaser: "I tell you there is a mistake in this bill."

Salesman: "I tell you there ain't! The bill is right."

Purchaser: "I tell you there is. I've got more money than that!"

Questions That Arise

CONCERNING THE BEST PROCESS IN MAKING A NOISELESS MOTOR; USE OF PRUSSIAN BLUE IN SCRAPING CRANKSHAFT BEARINGS; INFLATING TIRES WITH CARBONIC ACID GAS

[251]—What are the choices in the process of making a noiseless motor?

The first choice would be in favor of a design that does not utilize gears of any kind. The second choice would be in favor of a design that utilizes the least number of gears, and advancing this reasoning further, it would be proper to point out that selecting the types of gears that are most noiseless in their performance would be rational. Fig. 1 will help in the reasoning process; it shows two schemes of gearing considering a motor with two camshafts. The scheme at the top presents the pinion on the crankshaft, and the two halftime gears on the respective camshafts with center distances *a a*. Should there be but one camshaft, as in the L-cylinder designs, the halftime gear system and one large gear only would suffice. The lower diagram of Fig. 1 shows the pinion on the crankshaft, a lay gear above, and the two halftime gears in mesh with the lay gear. This is probably the most extravagant use of square cut gears that can be found in practice. The question of noise as it relates to these plans is very much involved in the center distances *a* between the meshing gears. If these distances are exactly right, and the gears are accurately cut, noise is reduced to the point where the muffling effect of the enclosing case renders the performance quite saisfactory. If the distance *a* is not right, no one of these plans would be worth considering, and so it would appear that noiseless performance does not depend so much upon the scheme employed, as it does upon accuracy of workmanship. If jigs are used in each case, it is no more difficult to use the plan with the two camshafts and the lay gear than it would be with one camshaft and one halftime gear meshing directly with the pinion.

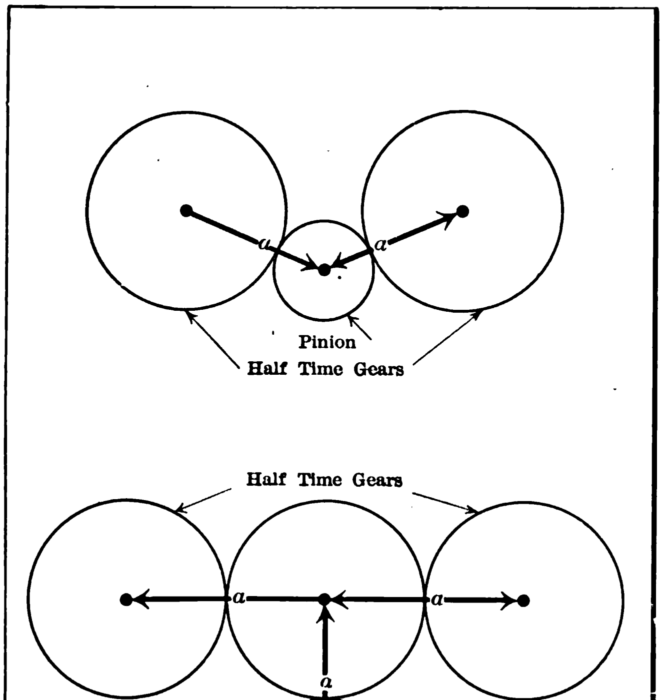


Fig. 1—Diagrams of the schemes of halftime gearing as used in automobile motors

Fig. 2 shows a plan that was used on the Moore motor, employing spiral gears, they being quite noiseless. The spiral pinion on the end of the crankshaft drives a laterally disposed shaft and the two camshafts are driven through pairs of spiral gears, one of which on the lateral shaft and the other on the end of the camshaft in each case. This lateral shaft also affords the driving means for the magnetos, of which there are two shown, and while this is an example of the profuse use of gearing, the fact remains that the performance was noiseless and satisfactory.

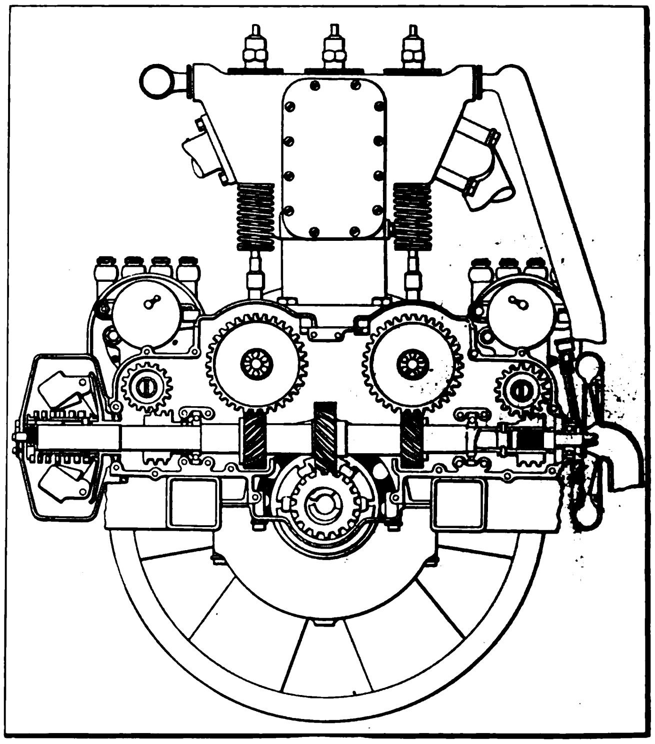

Fig. 2—Spiral gear system used on the Moore motor for driving the camshafts and magnetos

[252]—What is the character of the blue pigment which is used by machinists when they are scraping in crankshaft bearings?

Text books give for "Prussian blue" the name ferric ferrocyanide. Commercially, no such material is known. The blue that comes in tubes is made of Williamson's blue with perhaps other iron-alkali or cyanides, and perhaps aluminum-iron. The best way is to purchase this blue in these small tubes, very little being required in the scraping in of the motor. The mistake that the average workman makes lies in the profuse application of Prussian blue during the scraping operation; a perfectly even perceptible smear is all that is required.

[253]—Does inflating tires with carbonic acid gas have a detrimental effect on the rubber of the tires?

This method has been employed a good deal and no harm seems to come from the use of CO_2, but with heat generated by the friction with the road surface the gas expands and in Summer allowance must be made for this. What must be guarded against in pumping up tires is the use of exhaust gases from the engine; these have a detrimental effect.

A Tenement House Quarrel

MOTOR DRINKS TOO MUCH GASOLINE; MAGNETO COMPLAINS ABOUT OVERWORK; SPARK PLUG IS MISSING

"DRINKING gasoline cocktails," said Mrs. Magneto to Mr. Motor, "will bring you to an early grave; it takes all my time, no matter how much of a cat I become, spitting fire continuously, to keep you from having your system all clogged up with the carbon that gasoline tracks on its nasty feet; I told that fellow, Carbureter, who lives on the other side of you, to close the door which leads from his gasoline cellar, but he seems to be a most unaccommodating neighbor at best."

"Come now, Mrs. Magneto, please don't scold," said Mr. Motor. "You know very well that Dr. Quack prescribes gasoline cocktails as a regular diet for me."

"True," said Mrs. Magneto, "but you forget that Dr. Quack did not tell you to drink so hard; don't you know that you always have stomach trouble every time you take too much?"

"Aye, it is just as you say," said Mr. Motor. "I must get after that tenant of mine, Carbureter, and give him to understand that it is against the law to keep open after hours. Even if I am his most persistent customer; the best way to reform myself is to compel Old Carbureter to obey the excise law."

Now, little Miss Timer was listening to all this talk; she lives in a most inaccessible flat just back of Mr. Motor, facing Squire Flywheel's place. When conversation died out, little Miss Timer made bold to have a say: "Oh, Mr. Motor, aren't you afraid to put the law on Old Carbureter? Just suppose, for a moment, that you were to be cut off from your regular diet of gasoline cocktails, then what?"

Mr. Motor, never thinking that little Miss Timer was anything but a most giddy little child of poor parentage, awakened from his lethargy (having indulged in too much gasoline for over a week) and, touched by the solicitude of the girl, said, "Good for you; who would have thought it? I feared that you were so busy flirting with Willy Contact that you didn't know beans."

"Just to think of it, me flirting with Willy Contact? Never; I gave him his marching orders last week," said Miss Time. "Willy was limping around for several hours, kind a sour like; he seemed to be afraid of me, and the result was that I was all covered with the black dust that he kicked up every time he fell over something. I made up my mind that his spring was not working properly, and seeing Dr. Quack down there talking to Judge Battery, I called and he sauntered up to see me. Well, I told him of my suspicions and he agreed with me. He grabbed Willy Contact, took off his coat, and after looking him over carefully said: 'Willy, you certainly are in need of a bath; for the present I will be content to give you a new spring, but if I come around here again and find you with a dirty face, I will give you the bath of your life.' Willy said, 'Dr. Quack, Ounce-of-Prevention knows more about it than you do: had he been around I would not have had to eat my spring when I got hungry; he would have fed me some vaseline.' "

Just then a great commotion was heard up in Magneto alley; Willy Contact and the rest rushed away to see what was the matter, and just as they rounded the curve leading by Centrifugal Pump's house, they heard Fauntleroy Startingcrank say, "What do you think? Them Sparkplug boys have been sparking so long that every one concluded that they would marry and settle down, and now one of them is missing."

Helping a Novice Start His Engine

The other day I ran across Carrington on the train. Carrington lives near me and owns a Hurriup runabout and a touring car. Naturally we talked automobiles.

"It is a funny thing," said Carrington, reflectively, "how much a greenhorn can do to make trouble for himself. Yesterday I went to call on Gray, who lately bought a runabout like mine and is learning to run it. I got to Gray's house a quarter after three and was welcomed with more enthusiasm than if I had risen from the dead. I soon learned why. Since ten o'clock that morning Gray's man, aided by a chauffeur and helper in the garage nearby, had been trying fruitlessly to start the engine of Gray's runabout. Glad to see me? I should say they were!

"As Gray's runabout was of the same make as my own, I had a good idea of how to begin. For the fun of the thing I turned the crank two or three times, but of course without result. I noticed, however, that there was no compression whatever, absolutely not the faintest suspicion of it. On asking what they had done, I learned that in their efforts to prime the cylinders they had squirted gasoline by the cupful through the spark plug holes, and the gasoline naturally had cut every vestige of oil from the pistons. I took out the spark plugs to inject oil on top of the pistons, and found that the points of the plugs had been spread apart, I am positive, a quarter of an inch. Who did it, or why, I failed to learn; but of course no spark would jump that gap under compression. With oil supplied, the chauffeurs who had been cranking all day made themselves useful by cranking a little more, till the piston rings were properly oiled and would hold compression. Meanwhile I had set the points of the spark plugs a thirty-second of an inch apart, as they should be. I then tested the batteries and found them O. K.

"With the surplus gasoline worked out of the cylinders, and with proper compression and good sparks, I expected to see the engine start. I primed the carbureter and the crank was turned. The engine gave two or three spits and stopped. I turned the crank again. Two or three spits followed, and again the engine stopped. The third attempt resulted likewise."

"'Sounds as if the gasoline pipe was partly stopped,' said I. "Stopped? The gasoline was running a stream every time the float was depressed! The trouble was just the other way—too much gasoline. I asked Gray if he had changed the adjustment of the needle valve. He said he did not know, but he guessed he had, as he had done about everything else. I took a screwdriver and turned the needle valve down. It should have touched bottom in half a turn or less. It did not touch in a full turn, and I began to open my eyes. Fearing I might be turning in the wrong direction, I turned the needle back to its first position and marked it so I could return to the same position. Then I turned it again—one turn—two turns—and still no bottom. Three turns—still no bottom. 'Ye gods,' I thought, 'am I crazy?' Half a turn more, and it touched. I turned it back a scant half turn, cranked the engine a few minutes with the switch opened to expel the rich mixture, and it started and kept going. A slight adjustment, and the carbureter was O. K.

"The engine was running on the battery. I switched it over to magneto and the explosions stopped instantly. I looked at Gray. 'What have you been doing with the magneto?' I asked.

" 'I don't know,' said Gray, 'but the engine has been running on the battery for the past three days.'

"Well, I myself cannot imagine what that fellow had been doing, but when I looked at the magneto contacts I found pieces of his brake band mixed up with the contact points. I picked them out and cleaned the points, and the engine ran on the magneto as if nothing had happened.

"Before leaving Gray I warned him to dump out every bit of oil from his crankcase and replenish with fresh oil, as there was no way of telling how far the oil in the crankcase had been thinned by the gasoline squirted in to prime the cylinders."

Sec.

LOUISVILLE, KY., Oct. 10—The history of the Louisville Automobile Club is a record of ups and downs; of hopes and disappointments; of shadowy enterprises dimly outlined; a ray of light; a step forward in the march of progress; increasing confidence; added powers; notable achievements—success.

With a handful of charter members, the club was formed at the Galt House on February 27, 1903. This was in the early days of the automobile. In fact scarcely a year before, the first car ever brought to Louisville had been unloaded from a river packet.

At that time the automobile was an uncertain quantity and its quality was hardly comparable with modern types. It was a question whether or not it could be perfected to the point of general utility, or whether it would remain a toy. But these men who gathered around the big table in the blue room at the Galt House nearly eight years ago saw the light and prepared the way. They realized that the motor car had come to stay and that the influence of the automobile was destined to grow.

The rapidity of the growth of the club is shown by the fact that at the first meeting there were fifteen motorists present. At the second meeting, two weeks later, there were twenty-four and the constitution and by-laws were adopted. The organization was formally launched under the direction of the following officers: Ira S. Barnett, president; Biscoe Hindman, vice-president; and G. Wilbur Hubley, secretary.

There were in the early days of the automobile in Louisville few successes and many disappointments. Everybody was against the motor car to about the same degree that every one is now in favor of it. There was one bill introduced into the Legislature which had for its purpose the complete destruction of the motor car so far as Kentucky was concerned. It required that a man be sent in advance of the automobile to herald its approach.

Following its organization, the club immediately got busy with the pleasure end of its usefulness and a run to Shelbyville was made on May 30 of that year. That was the first run and a forerunner of the present day reliability run. The forty-five entries made the trip without serious inconvenience.

On St. John's Day, in 1903, the first auto races ever run in Louisville were conducted at Fontaine Ferry Park. The meet was successful, but, of course, none of the exciting trimmings—such as accidents and the like—marked the occasion, because the "speed god" had not risen to his present state of power.

In the early part of 1904, the club approved an ordinance for the regulation of automobiles on the streets of the city, fixing a speed limit in the central section of eight miles an hour and of twelve miles in the less thickly populated districts. This ordinance was passed by the General Council and is in effect today, but not frequently enforced.

Members of the club entertained the poor and sick of the city with an auto ride through the public parks of the city on July 4 of the same year. This was the origin of the annual orphans' day outing, which has been taken up by automobile clubs in practically every large city in the country.

About this time the question of a clubhouse was considered, but lack of funds made the project impracticable, and with much regret the matter was dropped. A few weeks later the organization adopted a club emblem, consisting of a wheel with an auto horn in the center. On the wheel was inscribed "Louisville Auto Club," but afterwards this design was changed so as to include the national emblem, including two wheels interlocked, with the name of the Louisville Club on the wheels.

The club in 1904 first turned its attention to keeping the streets free of glass and a stop was put to the nuisance. The organization also threw its weight against the Moral bill, then pending before Congress, which sought to tax motor cars $50. A committee was then appointed to secure better streets, and its labors resulted in great improvement.

The first automobile parade was held during the Summer of 1905, and it is chronicled as a success. Every year saw remarkable improvement and on June 13, 1906, during the presidency of George H. Wilson, who served as such from 1904 to 1908, the club gave a floral parade. There were thirty-five cars bedecked with flowers and the affair reflected much credit on those who had charge of arrangements.

A run to Shelbyville enlivened the program of the club the same year. However, there had been a waning interest in club affairs, the membership having fallen from 91 to 75 and things were going badly.

On June 7, 1906, the Kentucky Automobile Club was formed at the instance of the local club, and in the following year the club aided in the defeat of the Thompson bill.

The bill was aimed for the practical extinction of the automobile, following the lines of the Traction bill, requiring that a man be sent ahead of the machine on the public roads.

Early in 1908, the following officers were elected: Pike Campbell, president; J. F. Ross, vice-president; Eugene Straus, secretary, and Walter Kohn, treasurer. "Toots," the official organ of the club, came into existence during the year and at the close of the fiscal year, April, 1909, the organization had a membership of 111.

During the last year the activities of the club were more pronounced than ever before, and just now the Louisville Automobile Club is in a state of prosperity never before thought possible. The organization arranged several good road meetings and a standing reward was posted for information leading to the arrest and conviction of any person stealing or tampering with a machine. Radiator emblems were adopted and any car carrying the insignia of the organization receives the protection of the club.

A successful race meet was held during the Shriners' convention, under the auspices of the club. The activities of the year wound up with the first annual reliability and economy contest. The tour covered about 250 miles through the fairest section of the State and was run October 8 and 9.

For six years the club paid no salaries and the work was done by the officers, but since the elevation of Eugene Straus to the presidency, the organization has had a paid secretary. The rooms of the club were recently moved from the Louisville Hotel to the Commercial building.

The usual orphans' day outing was held on June 4. When the Glidden tourists passed through Louisville the same month they were right royally entertained by members of the club. Recently a chauffeurs' register was arranged at the club for the benefit of the motorists. It contains the names of all professional chauffeurs in the city and information concerning them.

The membership of the organization is now 412 and before the close of the year it is the aim of W. H. Argabrite, secretary of the club, to increase the number to 500.

Taxicab Furnishes the Requisite Speed

It is not too much to expect that caddies, at least the most apt of them, ultimately become adepts at golf. In bold relief with this acquired skill is the lack of it as it is portrayed by the amateur. It is not uncommon to note that the caddie is the better at the game, nor would it cause surprise were one of the rascals to put it over some of the talent whose clubs they carry.

This rather natural situation leads to strained relations at times; the player of little experience feels that the caddie holds him in a certain contempt.

As the story goes (with which some liberty is being taken here) a swell young beginner, in a swaggering makeup, accompanied by a stunning girl, no less made up, was sporting a caddie of the sort that knew the game.

They played a while (in a manner to arouse the ire of the caddie) and, making but little progress, turned to the caddie and said: "Do you think we will be able to get around the course before dark?" "If you hire a taxicab, sir," said the youngster.

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL-CLIMBS, ETC.

Oct. 18	New York City, Madison Square Garden, Electric Car Day at the Electric Show.
Dec. 1	Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Dec. 31-Jan. 7, '11	New York City, Grand Central Palace, Eleventh Annual International Automobile Show.
Jan. 7-14, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Manufacturers.
Jan. 15-21, 1911	Detroit, Wayne Gardens, Detroit Automobile Dealers' Association.
Jan. 16-21, 1911	New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4,'11	Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories, Exclusively.
Feb. 6-Feb. 11,'11	Chicago Coliseum, Tenth National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.
Mch. 4-11, 1911	Boston, Mechanics' Building, Ninth Annual Show, Licensed Automobile Dealers' Association.

Races, Hill-Climbs, Etc.

Oct. 21-22	Commercial Vehicle Test of Boston "American."
Oct. 21-25	Washington-Richmond Reliability Run of Washington "Post."
Oct. 22-30	Belmont Park, New York, International Aviation Tournament and Show of Licensed Automobile Dealers of New York City.
Oct. 27-29	Dallas, Tex., Track Meet.
Oct. 28-29	New York City, New York "American's" Motor Truck Contest.
Oct	Exhibition Auto vs. Aeroplane, Dutchess County Fair, Poughkeepsie, N. Y.
Nov. 3-5	Atlanta, Ga., Speedway Meet, Atlanta A. A.
Nov. 5-6	New Orleans, La., Track Meet.
Nov. 5-7	Los Angeles-Phœnix Road Race, Maricopa Automobile Club.
Nov. 7-11	Five-day Reliability Run of Chicago Motor Club, 200 Miles a Day.
Nov. 10-12-13	San Antonio, Tex., Track Meet.
Nov. 11-12	Savannah, Ga., Road Race, Savannah Automobile Club, and Grand Prix, Automobile Club of America.
Nov. 24	Santa Monica Road Race, Los Angeles, Cal.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

SOME confusion seems to have been brought about by the rather good performance of the long-stroke, single-cylinder motors as they are now being designed abroad. These motors perform extremely well and they are economical of fuel, which is the important point in France in particular, and in Germany to some extent.

* * *

IT is not believed that the long-stroke, single-cylinder motor is much in demand in this country; the question of fuel economy is not as yet a serious factor here, nor is there any likelihood of a fuel shortage for some time to come. The American automobilist, take him as a general proposition, abhors a "one-lunger."

* * *

THERE is a certain demand for relatively low-priced, single-cylinder automobiles, and this need is being adequately cared for by builders who appreciate the fact that the American automobilist who selects a one-cylinder car wants it for a more or less utility purpose, nor would he thank any maker or person for information which would permit him to speed the car up beyond its normal capability.

* * *

THE fact that the long-stroke, single-cylinder cars, as they are made in France and Germany, are so designed that they will travel at a high speed and accomplish other road stunts puts them beyond the pale of use under the conditions as they have to be met in America.

* * *

THERE is one other foreign situation that is being commented upon, involving the use of wire wheels, and it is not uncommon to hear automobilists say that the wire wheel is likely to come to America and be a factor in automobile work. The probabilities are that the wire wheel, as it obtains in England, will gain favor in America when the hickory forests of Missouri are depleted, and not before.

* * *

PROPERLY made wood wheels are so eminently satisfactory that they have been used in vehicles from 4000 B. C. down to the present time, and the only countries that do not prefer them are those which are without a native supply of hickory. This wire-wheel question is in the same category as the single-cylinder, long-stroke motor. Local economic situations favor the special line of products that will best accomplish the purposes, compensating for a famine of material of the right kind in the respective cases. In France they are short of gasoline, and in England hickory is scarce.

* * *

COMFORT and convenience are ruling considerations in body work at the present time, and in a new design as presented in THE AUTOMOBILE this week the convenience of the owner is consulted.

* * *

THIS particular body is of the enclosed type with inside control, and if the owner elects to drive, the seating capacity from his point of view is for three persons, but if a chauffeur is employed the seating capacity is then limited to the occupants of the commodious rear seat. The space alongside of the driver's seat is reserved for the entrance, making the same unusually inviting, the idea being to afford the absolute limit of comfort and agreeableness of the surroundings in town car work.

* * *

THERE seems to be an unusual degree of complication in connection with the A. A. A. sanction, which was finally given for the Bay State racing event involving the presence of outlawed drivers. Whether or not the reviewing committee will be able to get at the bottom facts remains to be seen; in the meantime, it looks like a blow at clean sport, coming rather too soon behind the late Brighton Beach affair, which, from the point of view of the spectators who paid the bill, reflected discredit upon the sanction, and should have discouraged "rubber stamp" methods of issuing sanctions. If it can be shown that unruly outlaws are out of control for the moment, nothing remains but to suppress them; but if it is a clean case of "the means for the end" there is work for an honest investigating committee to do.

* * *

PERHAPS there is nothing of such vital importance to the owner of an automobile as the condition that will induce longevity in the tires, and in an article that appears elsewhere in the paper this week this problem is handled fittingly; instead of taking up space in complaining about the deterioration in tire quality, the entire article is devoted to a clear and lucid statement of the facts as they confront the man who must pay the bill.

News of the Shows

PLANNING FOR THE IMPORTERS' DISPLAY—EXHIBITION OF CARS AT AVIATION TOURNAMENT—ELECTRIC SHOW CLOSES—DECORATIVE FEATURES AT THE GARDEN

THE importers of foreign automobiles have planned the most comprehensive show of their wares that has ever been held on this side of the ocean. The show will be held in the ballroom of the Hotel Astor from January 2 to 7, 1911.

Nine concerns have signed up for space to date and similar action on the part of six other companies is looked for in the immediate future. Space allotments will be made October 24.

Arrangements for the show are in the hands of the following committee: Paul La Croix, chairman, and Messrs. Demorest and Lascaris.

The big ballroom of the Astor will be divided into fifteen spaces for exhibition purposes, if a full representation is secured. The following cars have signed up: Darracq, S. P. O., Renault, De Dion, Itala, English Daimler, Benz, Panhard and C. G. V. Like action is expected of the following: Hotchkiss, Fiat, De Deitrich, Mercedes, Isotta and Zust.

In the list are eight French cars, four Italian, two German and one British automobile.

Classic Fountain at Garden Show

One of the strikingly attractive features of the coming Eleventh National Automobile Show, which is to be conducted at Madison Square Garden from January 7 to 21 by the A. L. A. M., will be the pergola fountain, in the shape of an arc at the entrance to the amphitheater.

The fountain is in the form of a low abutment of gray stone, in the front of which is carved a long settee. It will have a trough-like basin and at each end water will spray from the mouths of griffins and gargoyles. The falling water will be electrically radiant, made so by iridescent and cunningly hidden lights. Artificial water plants from which will radiate vari-colored lights will be in the pool and natural water lilies and gold fish will be mingled with them.

The fountain is overhung with wistaria, which clings to a netting of lattice work and gracefully entwines itself about the eight marble-white Doric columns which support the pergola. Four bay trees adorn the front of the fountain.

Auto Show at Aviation Tournament

With a prize list totaling $72,300 and including $10,000 for the swiftest flight from the starting line at Belmont Park, around the Statue of Liberty and return, six other prizes averaging $5,000 each and a dozen others ranging from $1,000 to $4,000, the first International Aviation Tournament to be held in the United States will open Saturday and continue for nine days.

Many world-famous aviators with their machines will take part in the various events carded.

In connection with the tournament there will be an exhibition of automobiles and accessories. This part of the show will be held in the betting ring, which affords ample space for such an undertaking.

Among the cars that will be shown are the following. Cadillac, Peerless, Mitchell, Chalmers, Stevens-Duryea and Cole "30." The list of accessory makers includes the following: Livingston radiator; Henry Ducasse, motors; Simms magneto; Peter A. Frazee and Company; Bosch Magneto Company; Hartford Rubber Tire Works; Marburg Brothers; Mea magneto; Bliven & Carrington, greases; John A. Roebling Sons & Company, wire and tubes; Metz Aeroplane Company; Aerial Navigation Company, propellers; American Propeller Company, propellers.

Electrical Show Ends in Blaze of Glory

Literally in a blaze of glory the Fourth Annual New York Electrical Show came to a finish at Madison Square Garden Thursday evening. The great hall was packed at almost every session. Among the exhibitors were: The Anderson Carriage Company, Detroit Electrics; Babcock Electric Carriage Company; S. R. Bailey & Company; the Baker Motor-Vehicle Company; General Vehicle Company; the Lansden Company; Studebaker Brothers' Company, of New York; Edison Storage Battery Company; Electric Storage Battery Company; Gould Storage Battery Company; the New York Edison Company; Philadelphia Storage Battery Company; United States Light & Heating Company and the Westinghouse Electric & Manufacturing Company.

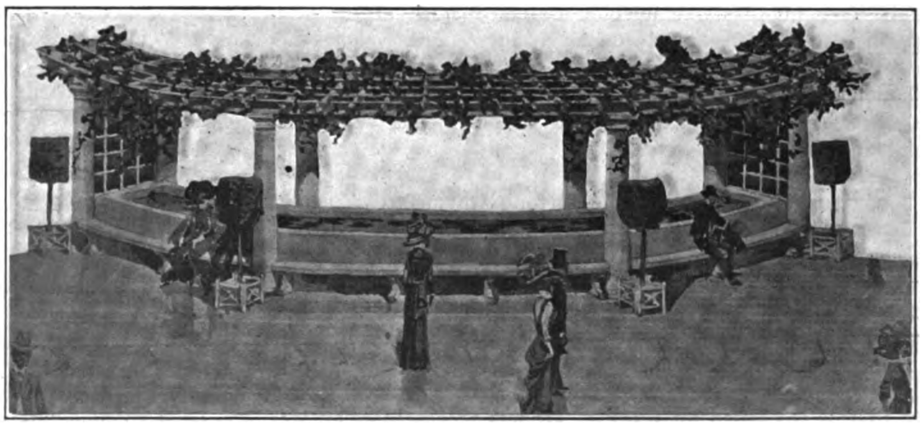
On Tuesday the First Annual Convention of the Electric Vehicle Association of America, a conference between the vehicle men and those identified with the installation and operation of central charging stations, was held in connection with the show. W. H. Blood, Jr., president of the association, presided.

Other addresses were by the president, W. P. Kennedy, L. A. Ferguson, S. C. Harris, Day Baker, F. M. Tait, J. T. Hutchins, G. M. Graham, Duncan Curry, Bruce Ford and Charles L. Eidlitz.

Oldfield, His Car and Partners Barred

Barney Oldfield, who was suspended by the Contest Board recently for advertising his participation in an unsanctioned automobile race meet, was formally disqualified by that board, Wednesday, in special session. This action was taken as the result of the race meeting at the Readville track last Friday, when he pushed his way through the officials and made two circuits of the track.

His car, a Benz, is also officially banned and barred indefinitely, and William H. Pickens and J. Alex. Sloane, manager and advance man for Oldfield, are disqualified from participation in any sanctioned meet either as owner, entrant, driver, manager or in any other capacity.



Design of fountain that will be a decorative feature of the A. L. A. M. show

The Week in Detroit

NEWS NOTES FROM MICHIGAN'S MOTORING CAPITAL—OWEN COMPANY TO TRANSFER ITS ACTIVITIES TO LANSING—CANADIAN COMMERCIAL COMPANY ORGANIZED

DETROIT, Oct. 17—The Owen Motor Car Co., of Detroit, has been absorbed by the Reo Motor Car Co., of Lansing, and it is announced that the high-class cars build in Detroit by the company since its formation a year or more ago will hereafter be turned out in Lansing. R. E. Olds states that the Owen company will be greatly strengthened financially, and that the output will be materially increased. From the outset the Owen Motor Car Co., invading the high-priced field, had been successful, and the Detroit plant had been run to capacity turning out cars.

The past week witnessed the organization of the first Canadian commercial motor car company. All the parties interested in the new enterprise, with one or two exceptions, are business men of Windsor, just across the river from this city. The company will be known as the Canadian Commercial Motor Car Co., and will manufacture the "Canadian Car," with a capacity of 1,800 pounds. The capital stock is $40,000. Celestine Thibault is the principal backer and president of the concern. The other officers are: Vice-president, J. G. Gagnier; secretary-treasurer, Charles R. Tuson; general manager, Charles F. Howse. Ernest D. Craig will be sales and advertising manager.

News comes from Hamilton, Ont., that a deal has been practically closed there for the merger of the Baynes Carriage Co., of that city; the American Road Machine Co., of Canada, located at Goderich, and two Detroit motor car companies under the name of the Acme Motor Carriage & Machinery Co., with a capital of $1,000,000.

Some 70 sales managers of the General Motors Co. met in Flint last Wednesday and Thursday to discuss plans for the selling campaign of 1911.

The Day Automobile Co. has been organized in Detroit, with a capital stock of $300,000, of which $200,000 is paid in, and will engage in the manufacture of the Day utility car, an automobile designed especially for the use of farmers, and which has a convertible body that makes it either a pleasure or commercial car. The present plans call for an output of 1,000 cars in 1911. Officers of the company are: President, Thomas W. Day; vice-president, Hugh Jennings; secretary, Cameron F. Roberts; treasurer, Wallace E. Brown.

How United States Motor Co. Will Share Profits

Benjamin Briscoe, president of the United States Motor Company, has announced the details of the co-operative plan by which the employes of the company are to be given an opportunity to share in the ownership of the company. The company offers its 7 per cent. cumulative preferred stock at the market price to be determined August 1, 1911. These shares are to be paid for in installments within two years. An amount of common stock equal to 1-4 of the preferred shares disposed of to employees will be trusteed and the dividends set off to the holders of the preferred shares and applied to the purchase. In cases of default through dismissal or resignation pending full payment for the shares, the forfeited dividends or annual bonuses will be placed in a fund to be known as the "Employees' Honor Fund," which will be divided *pro rata* among the employees whose showing during the year is satisfactory to the company. Subscription to the issue is limited arbitrarily to a scale based upon the pay of the various employees.

For the purpose of establishing an English motor car company, which will be affiliated with the United States Motor Company, Mr. Briscoe has sailed for Europe. He was accompanied by Mrs. Briscoe and will be in Europe five weeks.

It is likely that the English concern will be known as the United Kingdom Motor Company and will be located near London.

It is the intention of the United States Motor Company to transfer its designs and duplicate tools to England, but to purchase its machinery in that country.

The efforts of the United Kingdom Motor Company will at first be devoted to the United Kingdom, Germany, Russia. After branch houses have been established in these territories it is likely that the products of the organization will later be sent to all important European countries.

Automobile Activities in Pittsburg

PITTSBURG, PA., Oct. 17—The Automobile Dealers' Association of Pittsburg has named the following committee to arrange for the 1911 show at Duquesne Garden: Robert P. McCurdy, chairman; A. X. Phelan and F. D. Saupp. W. N. Murray, president of the Association, will be the ex-officio member.

The W. W. Bennett Motor Car Co. has been admitted to membership in the Automobile Dealers' Association of Pittsburg. It represents the following cars: Jackson, Buick, Waverly Electric, Franklin, Peerless, Belden, Woods Electric, Stoddard-Dayton, Overland, Maxwell, Cadillac, Pierce, B. & L. Electric, Marion, Hudson, Locomobile, Lozier, Packard, Pope-Hartford, Stevens-Duryea, White steam and gasoline, Elmore and Winton.

Big Jersey Home for Hudson and Peerless

NEWARK, N. J., Oct. 17—Work toward the construction of what will be the largest structure in this State devoted to automobiling interests has been started at 37-39 William street, this city. The building will be occupied by A. Elliott Ranney & Co., New York and New Jersey agents for the Hudson line, and the Peerless Motor Car Co., of New York. They will occupy the structure jointly. Both firms are at present located nearby.

Another Suit Filed by the A.L.A.M.

Announcement has been made that suit for infringement of the Selden patent had been filed against the W. A. Wood Automobile Manufacturing Company, of Kingston, N. Y., which is in the southern district of New York.

The bill of complaint states that the Wood company is manufacturing gasoline cars that infringe the patent.

Dexter Heads the Grout Company

At the annual meeting of the Grout Automobile Company, Orange, Mass., last week the following officers were elected: President and secretary, G. E. Dexter; treasurer, E. S. Hall; directors, E. S. Hall, G. E. Dexter, H. F. Misener; general manager, E. S. Hall; selling agent, Reginald Wade; superintendent of factory, H. F. Misener.

Cameron to Visit Olympia Show, London

W. H. Cameron, chief engineer of the Willys-Overland Automobile Company, sailed for Europe yesterday on the "Lusitania." Mr. Cameron will visit the Olympia show in London and will inspect the automobile situation generally on the continent. Mrs. Cameron accompanies him.

Aerial Events

BY MARIUS C. KRARUP. A CURRENT RECORD OF ESSENTIALS IN THE PERFORMANCES OF AVIATORS AND AERONAUTS. A WEEK FULL OF MOMENTOUS DOINGS

THE second stage of ballooning and the first stage of aviation are rapidly drawing to a finish. Almost every hour is historic. These days witness practical trials which must go far to settle convictions as to the actual state of progress in air craft. All theories withdraw to the background and await results, no less sure of themselves perhaps but less confident of a hearing. Last Saturday morning the motor balloon "America" was released from its shelter at Atlantic City, after many delays and popular disappointments, and Walter Wellman with Melvin Vaniman, his engineer, and four helpers finally set their course for somewhere in or at the Atlantic Ocean, preferably Europe. They landed 400 miles south of the starting point and 100 miles off Cape Hatteras. The event did little save to make the performance a notable event in financiering, sport and newspaper enterprise, sufficiently remarkable to excite wonderment and even enthusiasm from the standpoint of all who love modern adventure, and sufficiently complicated scientifically and mechanically to confuse conclusions and bolster new and treacherous hopes for the future of the elongated gas bag, nine-tenths drifting, one-tenth driven. Only 24 hours later, while the coast of Nantucket was busily conversing with the Marconi apparatus of the "America" somewhere in the offing, the Clément-Bayard motor balloon was started from Compiègne, northeast of Paris—it was 7.15 Sunday morning—and headed for London. A favorable wind sped the apparatus at the rate of 40 miles per hour in almost the right direction. The motors had easy work, and six hours later the daring deed was done and the pilot, Mr. Clément, Jr., deposited his crew of five and his delighed passenger, Arthur Du Cros, of the well-known British family identified with the history of automobile tires, among the gasping denizens of the largest city in the world. Almost at the same time—reckoning with the long minutes of history—and more precisely beginning Saturday, Oct. 22, some thirty noted aviators will demonstrate their art at Belmont Park on Long Island, and the interested public, comprising the entire civilized world, holds its breath in expectation. What new stunts will be done in this new loop-the-loop game in which the daring entertainers know not in advance when or where or how the loop comes? Who shall win the tempting prizes, aggregating at the present moment $72,000 and likely to be swelled further through the persuasive force of things doing? And—passing thought—whose shall be the names to be stricken with sad nonchalance from the roster of active conquerors of the atmosphere, that heroic list which keeps so remarkably constant in length of late, losing by cautious desertions, by disablement and by the final cross almost as many devotees as it gains from a sportsmanlike craving for new sensations or from lust for glory and its emoluments?

And from abroad comes the report that Henry Wynmaelen with the latest model of Henry Farman biplane, after a few days ago making a new altitude record of 9,185 feet with the same machine, succeeded in capturing a $35,000 prize by flying with a passenger from Paris to Brussels and return, a total by the air route of about 350 miles. Wynmaelen covered 234 miles on the first day and the rest on the second, Oct. 16. Legagneux, also with a Farman biplane, tried the same feat, but suffered a slight accident when descending 116 miles from the finish. Wynmaelen's time was 27 hours 50 minutes and 27 seconds, more than 12 hours being used for rest and care of the motor.

At St. Louis, Mo., ten spherical balloons set out for a longer international prize race on Oct. 17

The Wellman expedition, at the present moment, bids for comment rather than description.

The motor balloon can reach greater heights than the aeroplane, perhaps, and its motor troubles may be remedied en route. But it owes its reputation in this respect to the spherical balloon. No dirigible has carried power to great height. Constructed in enormous dimensions it can carry higher propulsive power than the aeroplane, but each additional horsepower is discounted in advance by the additional volume and areas to be forced against the air currents. It can stay in the air a long time, but not necessarily where wanted. All confidence in its possibilities should be measured in comparison with those of the aeroplane. As a destroyer in war and a maker of peace—and it is as a peacemaker that Wellman proposes to demonstrate its superiority, he says—its capacity for controlled operation at high altitudes is indispensable, and it seems unfortunate that the attachment of the so-called equilibrator to the "America," for the avowed purpose of holding the airship down to within 200 feet from the surface of the sea, has been considered necessary, since the employment of this device renders the whole demonstration null and void for its declared purposes.

Undertaken gaily and carried out with the dash which, for example, Moissant put into his flight from Paris to London, the crossing of the Atlantic in a dirigible would have been glorious sport, worth its price and its reward, in case of success, but as the last squeeze in a frantic search for conspicuous achievement and coupled with the profession of lofty purposes on one side and keen pecuniary arrangements on the other, it challenges a close examination of the pretensions with which it is heralded. Unfit to travel over land, as the preparations proved it to be; unfit to cross the ocean unless the winds favor it exceptionally, as proved by its coastwise course; unfit to reach the altitudes where lies the only perceivable utility of the motor balloon in competition with aeroplanes, the "America" outfit—so skillfully named to enlist a favorable sentiment—offers apparently no guarantee that anything which may be accomplished with it once may be accomplished again when wanted, or within a month after it is wanted, or that anything which can be done with it at any time will serve any useful purpose.

As between the aeroplane promised by Lilienthal, Chanute and others, which stays in the atmosphere for days by virtue of large areas, small weight and perfected devices for utilizing air currents for its support, and the motor balloon rendered capable of similar service though at much lower speed by enormous size and scientific equipment, the choice, with regard to the probability of seeing either of these creations of hope and imagination materialized, seems to favor the former among those who reason for engineering purposes rather than for publicity.

How to Make a New Altitude Record.

Start from Leadville. This city has a recorded altitude of about 11,000 feet. The country is fairly level for several miles both southerly in the direction of Malta and westerly toward Tennessee Pass on the "great divide." A recorded rise from the ground would be a world record. The gradual rise of the ground from the Missouri River to this plateau of the Rockies gives opportunities for trying out the carbureter adjustment required for best results; also for trying out the proportions between aeroplane area and motor power and the most favorable relation between speed and angle of incidence, and the angle of incidence or tilt which gives the best fore-and-aft balance of the machine, and therefore the smallest loss of efficiency from the use of an elevating rudder must also, other things equal, give the highest altitude.

At Quitman, Ga., on "Round-the-State" Run

Preparing for Grand Prize and Smaller Events

Savannah, Ga., Oct. 17—Entry blanks for the Grand Prize race and its auxiliary light-car races have been issued by the Savannah Automobile Club. Save for the substitution of the names of Harvey Granger, Frank C. Batty, Arthur W. Solomon and William B. Stillwell for those of the officials of the Motor Cups Holding Company, and of Savannah for the Motor Parkway, the blanks for the Grand Prize entrants are identical with those that had been prepared for the original Long Island contest.

Entries close November 5 and so far the indications are that the list will be considerably larger than had been expected. No limits are placed on the power and construction of the cars save that they are limited in width to 68.89 inches; must have their exhausts directed away from the ground; must have a motor-driven reverse gear and must be certified as safe by the Technical Committee of the Automobile Club of America.

The course as approved by the club is 18.50 miles long and the Grand Prize racers will circle it 22 times, making the total about 407 miles. The race will be held November 12.

On the preceding day two road races for light cars will be given. The route will be the same as that to be taken by the big racers, but the number of circuits will be cut down to 15 in one case and 10 in the other.

The cars eligible to entry in these classes correspond in a general way to Divisions 2 and 3 of Class B, according to the rules of the Contest Board, but there are a number of exceptions and options not included in the terms of the "stripped stock chassis" class.

The longer race scheduled for November 11 is for the Savannah Challenge Trophy, a cash prize of $1,000 and various minor awards. The cars eligible must have piston displacements ranging between 231 and 300 cubic inches, and conform with the requirements of the Automobile Club of America's rules. The distance for this race is approximately 277.5 miles.

The Tiedeman Trophy race is for cars of from 161 to 230 cubic inches displacement and the mileage of the course is 185. The entrance fee in either of these contests is $250 a car; two for $400 or three for $500.

Considerable work has been done to put the course in proper condition for racing and 100 loads of gravel have been used in repairing bad spots. The contract for oiling the entire 18.5 miles of the course has been let and this phase of the work will commence immediately.

The stands this year will be located on either side of the course, the grandstand on the outer side at Fifty-second street and Waters road and the press and official stand on the inside, connected by an elevated passage-way over the track. South of the main stands, the general admission stand will be built on the inside of the course. Each of the stands for the public will be 1,000 feet long and it is estimated that they will hold 40,000 persons.

"Round-the-State" Tour

Atlanta, Ga., Oct. 18—Unique in its conditions is the "Round-the-State" automobile run of nine days that started Monday morning. There were about 75 starters but the cars were not required to begin at a definite line, and the noon and night controls have been divided up so that it will be possible to entertain the big caravan.

In a general way the run is following this course: Atlanta to Macon; to Albany; to Bainbridge; to Valdosta; to Waycross; to Savannah; to Augusta; to Athens, and back to Atlanta. Sunday will be spent in Savannah. Road conditions during the first three days were excellent. The entered cars include: Two Halladays, one Ohio, three Maxwells, three Columbias, eight Buicks, two Primos, one McFarlan 6, two Thomas Flyers, one Lozier, one Franklin, three Knoxes, two Nationals, four Whites, two Coles, four Overlands, one Speedwell, two Cartercars, one Selden, one Hudson, one Everitt, two Chalmers, two Ramblers, three Haynes, five E-M-F's, one Abbott-Detroit, one Firestone, two Mitchells, one Olds Special, one Brush, one Pullman, two Hupmobiles, one Case, Oakland and Velie.

Mount Vernon Club to Stage Races

The second automobile race meet under the auspices of the Mount Vernon Automobile Club will be held Saturday afternoon, October 22, at the Empire City motor speedway. Seven events are carded and entries for each are said to have been received in satisfactory volume. The races include two 10-mile events under Class B; one 10-mile event under Class C; a 5-mile free-for-all handicap; an owners' race at 5 miles, limited to members of the Mount Vernon Automobile Club, to be driven by the owners; a club handicap at 10 miles and an hour race, limited to cars with piston displacements of from 231 to 300 cubic inches. This race, which will be the feature event, will bring to the winner the possession of the Splitdorf trophy.

Otto F. Rost, who successfully managed the former meeting of the club, is general manager of this meeting and is chairman of the contest committee.

The affair is fully sanctioned and recognized.

Big Entry List in American Truck Test

The commercial vehicle endurance and economy test scheduled for October 28-29 on the streets of New York City, under the auspices of the New York *American*, has attracted an unusually large and representative field. A. H. Whiting is to be referee;

Savannah, Ga., on "Round-the-State" Run

SEVENTY-FIVE STARTERS IN THE NINE-DAY RUN THAT LEFT THE GEORGIA METROPOLIS LAST MONDAY

E. L. Ferguson, manager, and the chairman of the Technical Committee is A. L. McMurtry.

Electrics entered in the contest shall be known as Class A, while the gasoline trucks are Class B. There are five divisions under each class, according to capacity. A running schedule of 5 1-2 hours for each day has been arranged for the group designated as the Distributing Group, which will travel with half loads and will stop frequently as if in service as distributors, while the Transfer Group will cover 65 miles a day.

Illinois to Have Good Roads Association

Springfield, Ill., Oct. 17—An important step in the matter of good roads in the State of Illinois has just been taken by the organization of a State-wide association at Bloomington, which will have for its avowed purpose the up-building, repairing and general care of every road in the State. The association will be known as the State Association of Township Highway Commissioners and Town Clerks of Illinois. Officers elected were as follows: President, George W. Haywood, Joliet; vice-president, Clayton Mays, Normal; secretary-treasurer, W. D. Hall, Joilet; members of executive board, B. H. Myers, Naperville, John Schloesser, Bloomington, F. H. Hannifield, Tremont, A. P. Ferguson, Griggsville, Thomas Lyman, Champaign, B. G. Gehrig, Centralia.

Santa Monica Race an Open Event

Los Angeles, Oct. 17—Entry blanks are out for the second annual Santa Monica Road Race which will be run Thanksgiving Day. Manager Dick Ferris has made the big car race an open event, and many entries are expected.

Ten thousand dollars in cash prizes have been guaranteed for these races in addition to the $1,000 Dick Ferris trophy and the $500 Leon Shettler cup. The entire list in each event is limited to sixteen, and the course is eight and two-tenths miles.

Five Miles of Cars in Cleveland Parade

Cleveland, Oct. 17—One of the features of the Cuyahoga County Centennial at Cleveland was an automobile parade on Tuesday, Oct. 11, to celebrate the opening of the new Rocky River Bridge, which is the largest concrete span in the world. There were about 1,500 cars in line, making a parade five miles long and which took two hours to pass a given point.

Savannah Races Stir Automobile Row

Scarcely a manufacturer represented along Automobile Row will admit that his car will not be entered in one or more of the contests to be staged at Savannah next month. The Coles and Falcars, winners in the light car races over the Vanderbilt Cup course this year, will try again, according to their makers. The victorious Pullman in its class at the Fairmount race will try to duplicate its excellent performance. A pair of Maxwell cars are promised as entrants in one of the smaller classes, and two Stoddard-Daytons are being prepared for the Grand Prize. The Benz and Fiat trios have been nominated for the big race, and so has the speedy Lozier. There is a possibility of a Correja, a Midland, and an Amplex. Three Abbott-Detroits are said to be ready for the Tiedeman Trophy race. The Marquette-Buick pair are being prepared for the Grand Prize. Two Marmons have been named for the big race and another for the Savannah Challenge Trophy. Three Nationals may try conclusions.

At Hudson headquarters it was said that a car was being made ready for racing and if its performance in preliminary work met with expectations it would be entered in one of the races. The Ford company declared that it would be represented. As a matter of fact only two definite statements were made among the handlers of automobiles on the row that their cars would not compete.

The additional foreign entries which have been mentioned have not yet been definitely made. Representatives of the Savannah Automobile Club will be present at and before the coming race meeting at Atlanta and will make an effort to swell the entry list from among the contestants at the Speedway meeting.

All indications point to record-breaking fields in all three events, the entry list already giving indications of surpassing in size the most sanguine expectations of the promoters, and including many of the fastest cars in the country.

Ford Wins Bloomington Reliability

Springfield, Ill., Oct. 17—T. A. Harper, driving a model T Ford, was awarded the cup for winner of first place in the reliability run of the Bloomington, Ill., Automobile Club, after two other drivers, J. L. Murray, Buick, and Velde, his partner, had withdrawn. The two other machines which had finished with perfect road scores, Orlo Price's Warren-Detroit, and Harry Arnold's Rambler, were penalized at the meeting of the contest committee, which ascertained that these drivers had failed to observe a rule which called for all machines to come to a stop at all railroad crossings.

This left Murray and Velde at the top of the list alone. Harper stood second. Because of the fact that this firm had been instrumental in promoting the affair, they withdrew their cars from the list of winners, and the first prize, a handsome silver loving cup, went to Harper.

First Successful Coast Ru

SAN FRANCISCO, Oct. 13—The Pacific Coast has had its first real endurance run, and motordom in this region is discussing the result of the contest and reviewing the work of the different entrants. The run was held under the auspices of the San Francisco Motor Club and covered a 470-mile course from San Francisco to Lake Tahoe and return. There were eleven entrants in the tour, nine of which checked in the finishing control with perfect scores. The tenth was penalized for failing to reach the fifth control on the homeward journey within the allotted time. The eleventh car met with a mishap on the last leg of the journey and was forced to retire from the contest, although up to the time it had crashed into a fence and broken a front axle it had held a perfect score.

The cars returning with perfect scores and the drivers were: Buick, Fred Gross; Buick, Frank Murray; Cartercar, E. C. Collins; Crawford, E. Stewart; Ford, E. L. Cutting; Knox, Bert Oaks; Maxwell, C. S. Harding; Rambler, Captain McCauley; Winton, H. L. Owesney.

The two cars failing to win perfect scores were the White steamer which was penalized for failing to reach one control on time, and the White gas car which slipped from the road into a ditch and broke the front axle.

The route was a well-selected one to test the reliability of the cars. Every conceivable sort of a road condition was encountered on some part of the trip. During the first portion of the trip fine boulevards were enjoyed; later dusty valley roads were experienced, then came stretches of rough foothill highways and later came the steep and heavy mountain roads with sharp curves that overlooked deep ravines. On the homeward trip rain fell and another road condition was encountered. The dusty sections of the road were converted into veritable seas of mud, and as most of the cars had not been equipped with chains the drivers had much trouble in keeping to the roads.

Winton crossing a bridge near the source of the Truckee river

The run started on Saturday morning at 7 o'clock, the cars being ferried to Oakland where the actual start began about 8 o'clock. Checked out at two-minute intervals the cars were given four hours and a half to make the city of Stockton, the first control, 84 miles from the start. The time allowance proved a generous one as the roads were good and all the cars were forced to loaf along toward the end of the journey so as not to check in ahead of time. After an hour's delay, during which time the tourists partook of lunch, the cars were again started. The second leg of the tour required the motor cars to make Sacramento, 52 miles away in 2 hours and 15 minutes. This schedule, while it was made by all the cars, required some stiff work as the roads in some places were in poor shape, undergoing repairs, and occasioned delays. A short rest of fifteen minutes was allowed at the Capital City and the cars were again set on their course to Auburn, 36 miles away. This route laid through the foothill region and the roads were in bad shape. Two hours were given to complete the distance, and again all the cars came into the control in the required time, but there was no loafing en route. At Auburn the cars were garaged for the night.

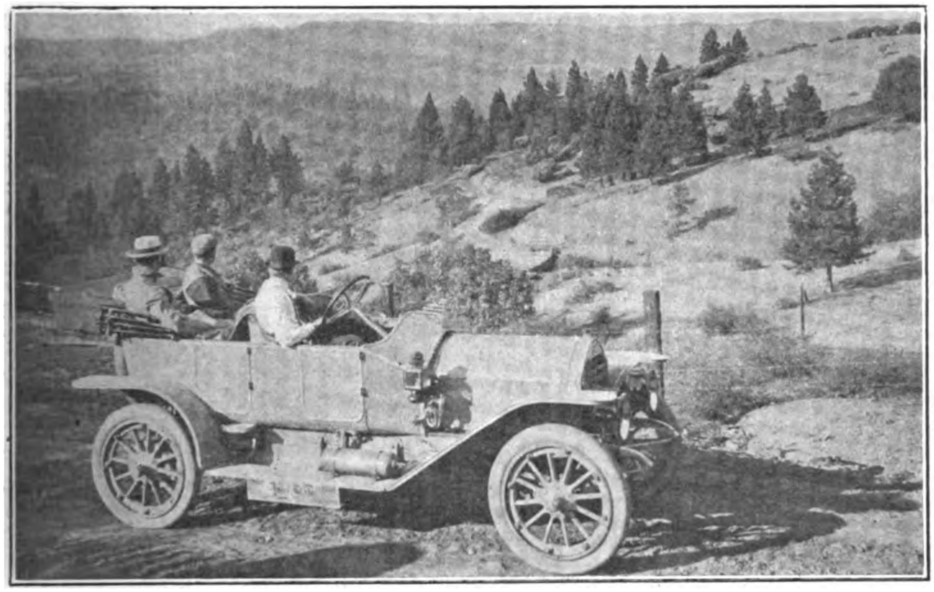
Rambler car on way to Summit, showing a well-made road and scenery that is magnificent

The second day's touring opened with the beginning of the real mountain portion of the journey, in which the cars were forced to ascend some seven thousand feet to drop some three thousand on the other side of the highest point to reach Truckee. The distance over the mountains was 68 miles and the cars were given six hours and thirty minutes to complete the distance. The same story regarding the ability of the entrants to negotiate the distance was noted here as at the other controls, all the cars reaching the goal in required time. The cars were checked out one hour later for Lake Tahoe, 16 miles off through the mountains. One hour and a half was given to make the distance, but this time was again too generous, and the cars made it within fifty minutes and had to remain outside the control until checking-in time.

ENDURANCE CONTEST OF SAN FRANCISCO MOTOR CLUB COVERS A 470-MILE COURSE OVER MOUNTAIN AND PLAIN

Sunday night was spent by the tourists at the Tavern on the lake. Some of the drivers took their cars off for small side trips on the lake shore and added to the mileage covered by their cars.

The home journey began Monday and took in the run from Lake Tahoe to Sacramento, a distance of 122 miles. The cars were given 13 hours to make the control and all, with the exception of the White steamer, which broke a brake shoe, reached the control successfully. The steamer, after making repairs, met with various other delays in the shape of being stalled by a mountain train that held the road for the good part of an hour until a section was reached which permitted the motor car passing. Then again a freight train prevented it from crossing through the snow shed for some thirty minutes. A rain and thunderstorm in the mountains which made the going dangerous reduced the running time, and later, in the darkness, losing the road increased the lost time to three or four hours until it reached the control.



Inter-State under scenic conditions in the Sierras that commands admiration

The last portion of the trip began Tuesday morning and embraced 136 miles from Sacramento to San Francisco through the San Joaquin and Livermore valleys, Dublin canyon, Hayward, Oakland, and by boat to Frisco. On its way to Livermore valley the White gasoline car slid from the road and crashed into a fence and was forced to remain out of the race. The other cars completed the journey in time to keep their winning scores, although the heavy rain that was falling caused the drivers much difficulty in getting over some of the grades.

All the contestants are enthusiastic over the tour and an effort is now under way to make it a yearly event. Scenically the course is without a peer in any section of the United States, and as far as the testing of the endurance powers of the cars is concerned it is without doubt equal to the best in the country.

A good look at Donner Lake from the road that skirts along the side of the mountains

Hilles Heads Delaware Association

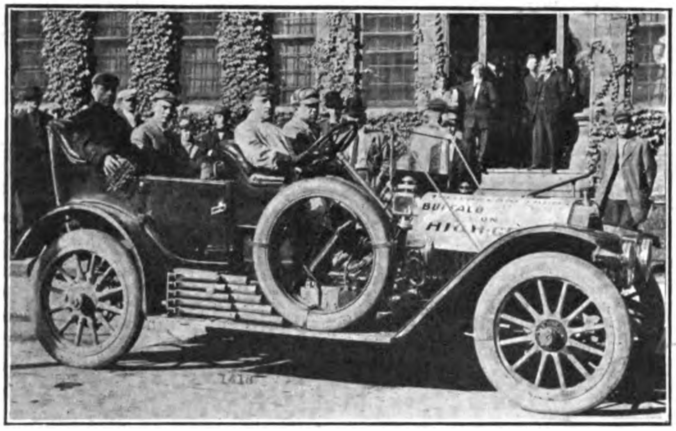
WILMINGTON, DEL., Oct. 15—The Delaware Automobile Association held its annual meeting here this week and elected the following officers: President, T. Allen Hilles, of Wilmington; first vice-president, Joseph Bancroft, of Wilmington; second vice-president, Wilson L. Cavender, of Smyrna; third vice-president, Joseph L. Cahall, of Georgetown; secretary, Charles G. Guyer, of Wilmington; treasurer, William Stanier, of Wilmington; executive committee, in addition to the above officers, John B. Martin, John B. Bird and Charles C. Kurtz, all of Wilmington.

Baltimore Club Elects Officers

BALTIMORE, MD., Oct. 16—The Automobile Club elected the following officers at the annual meeting: Dr. H. M. Rowe, president; Joel G. Nassauer, vice-president; H. M. Luzius, secretary; Thomas G. Young, treasurer; board of governors, John S. Bridges, C. Howard Millikin, James S. Reese, William A. Dickey, Joseph M. Zamoiski and Ernest J. Knabe. The club has adopted a progressive policy for the winter, pledging itself to increase the membership to 800, post road signs within 10 miles radius of the city hall, abolish bad street car and other crossings in the city and to establish with the Appeal Tax Court a uniform rate of taxation on various makes and models of autos. The club now has 421 members, an increase from 262 in May.

Stevens-Duryea Wins Prize

WILMINGTON, DEL., Oct. 15—In an automobile parade held in Chester, Pa., yesterday in connection with a "buy-at-home week" celebration a Stevens-Duryea car, owned and driven by Charles P. McCoy, of Wilmington, was awarded a silver cup valued at $100, the first prize, as the handsomest car in line. The machine had been decorated by Mr. McCoy's wife, who used 25,000 paper roses and 300 chrysanthemums.



1911 Model M 6-40 Thomas Flyer which is touring the east on high gear

—J. G. Miller, of Walla Walla, Wash., has the agency for the Elmore car.

—Burton A. Clark, of Boston, has joined the sales force of the E. R. Thomas Motor Branch Company, Boston.

—The White Automobile Company, of Baltimore, Md., has taken on the agency in that city for the Courier car.

—The F. H. Barshar Company, of Seattle, has obtained the agency for the Marion car in Washington, Idaho and British Columbia.

—LeRoy Van Patten, until recently with the Hudson Motor Car Company, is now advertising manager of the Alden-Sampson Detroit plant.

—W. H. Barnes, Rapid agent in Seattle, has secured a garage in Tacoma and will establish a resident sales and maintenance force during the next 30 days.

—The Frederick E. Murphy Automobile Company has begun operations at Third street and Third avenue, south, Minneapolis. The company will handle the Mitchell car.

—The Hudson agency in Baltimore, Md., is now in the hands of the Lambert Automobile Company which is also the representative for the Maxwell and National cars.

—The Monitor Automobile Works, of Janesville, Wis., is building three Monitor trucks for exhibition at the Chicago show. A hotel bus, an express wagon and a polished chassis will be shown.

—The Automobile Dealers' Association of Pittsburg has elected the following officers: President, W. N. Murray; vice-president, F. D. Saupp; secretary, Ed. C. McCurdy, and treasurer, G. P. Moore.

—The membership of the Seattle Automobile Club is now close to the five hundred mark, and it is expected that many members will have enrolled by the time when the annual meeting will be held.

—To demonstrate the utility of the Kelsey Motorettes manufactured in Hartford, Conn., by the C. W. Kelsey Manufacturing Company, two of these vehicles are to be sent across the country later in the season.

—The Velie Motor Vehicle Company has closed agencies with J. T. Curtiss & Company, Simsbury, Conn., and Frank E. Vallier, Lynn, Mass., for the right of sale of Velie cars during the season of 1911.

Short News of Interest

—The Goodyear Tire & Rubber Company has opened a branch salesroom in Toledo. The new concern is located at 909 Jefferson avenue, and will carry a complete line of automobile, motorcycle and bicycle tires.

—The capital stock of the Alton Motor Accessory Company, of Akron, Ohio, has been increased from $50,000 to $100,000, to provide for additional facilities in the plant. The plant is located on South street, Akron.

—The big garage and salesrooms at 310 Pike street, Seattle, are now occupied by W. H. Barnes, northwestern dealer for the Rapid Motor Vehicle Company, of Pontiac, Mich. A complete machine shop has been installed.

—An addition is being erected to the Empire factory in Indianapolis. The new building will have facilities for testing a number of completed chassis and will also be used for final assembling work and as a repository.

—John C. Speir has been appointed superintendent of the mechanical department of the Pennsylvania Auto Motor Company, Bryn Mawr, Pa., makers of the Pennsylvania car. Mr. Speir will assume control immediately.

Rambler "Hurry-Up" wagon recently purchased by the city of Sacramento, Cal.

—The Velie 40 has made its appearance in Portland, Ore. The John Deere Plow Company will distribute the line of automobiles in the Northwest, with headquarters at Portland. J. A. Crittenden is manager of the new branch.

—Hartford, Conn., is to have another show probably the last week in February, though the date has not been definitely determined. The attraction will be run under the auspices of the Hartford Automobile Dealers' Association.

—The George M. Merrill Automobile Company, of Spokane, Wash., have secured the agency for the Thomas Flyer for that territory, and will handle this car at 111 Pacific avenue.

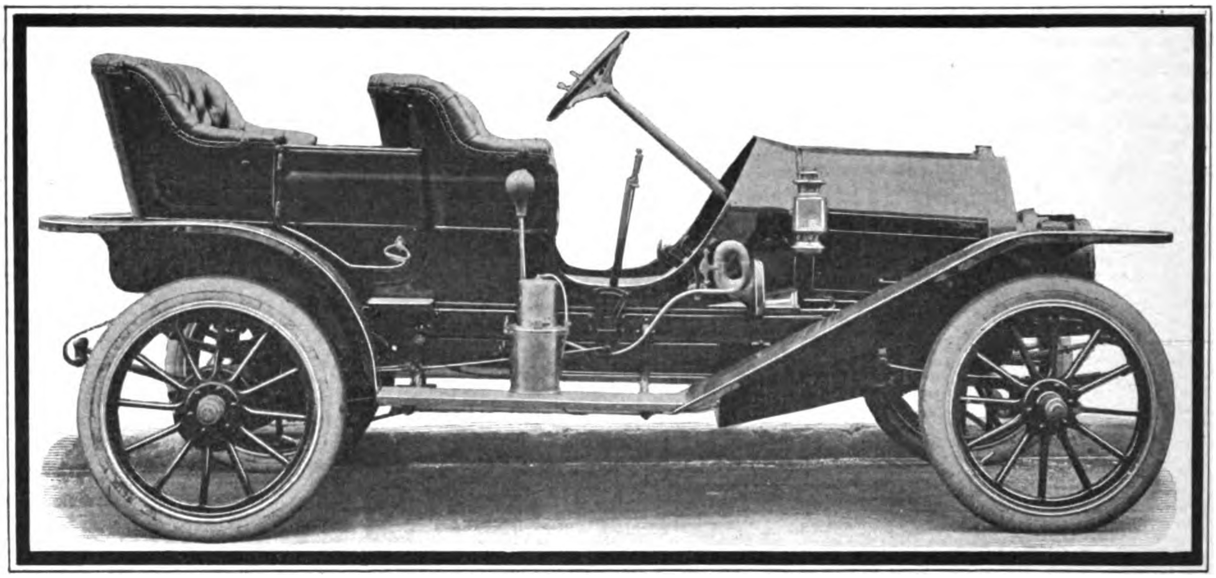
Among the Agencies

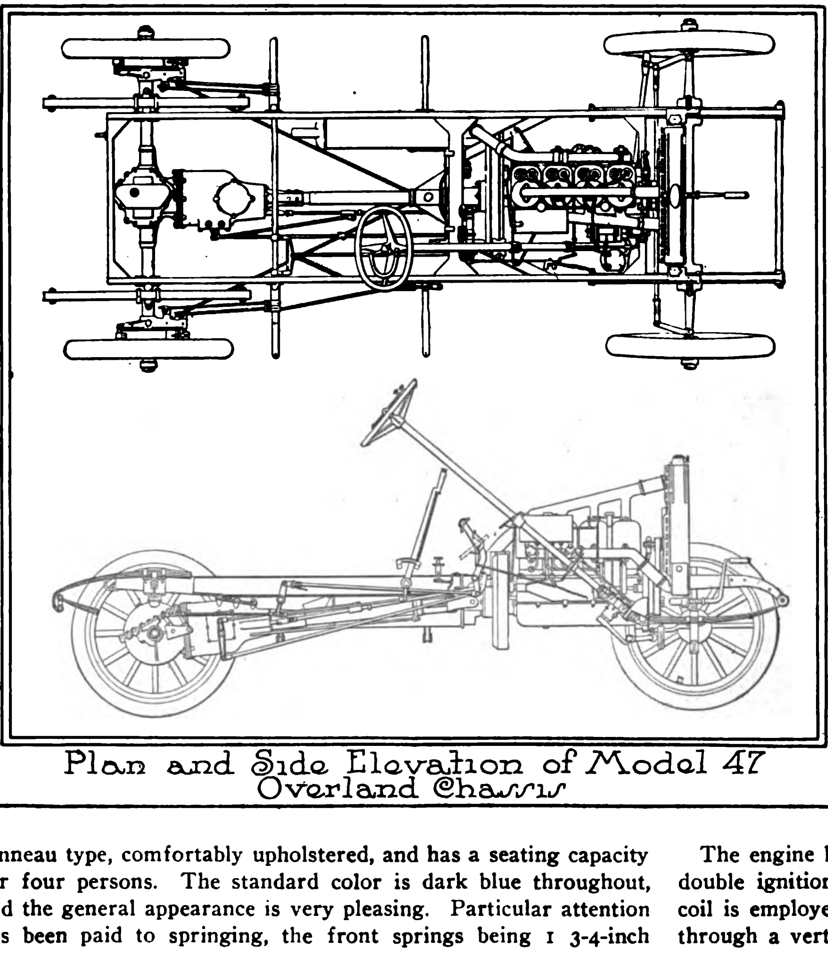
WILLYS-OVERLAND COMPANY HAS INTRODUCED A NEW MODEL, NO. 47, A LOW-PRICED DEMI-TONNEAU WITH A 19.6-HORSEPOWER MOTOR (A.L.A.M.)—OTHER AGENCY NEWS

THE Overland Sales Agency, 1657 Broadway, New York, has just received from the factory of the Willys-Overland Co., at Toledo, a new model which will be known as Model 47.

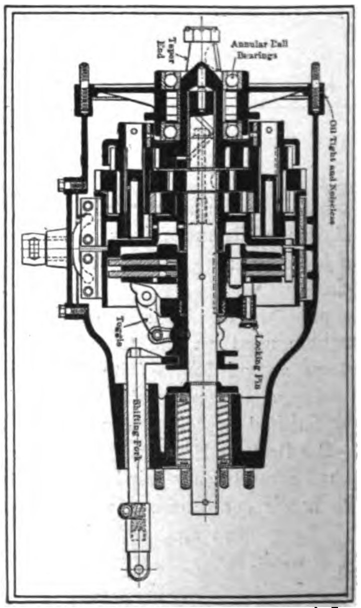
As will be seen from the illustration the body is of the demi-tonneau type, comfortably upholstered, and has a seating capacity for four persons. The standard color is dark blue throughout, and the general appearance is very pleasing. Particular attention has been paid to springing, the front springs being 1 3-4-inch semi-elliptic and the rear springs of similar dimensions but full-elliptic. The front axle is a stout drop-forging of I-section and the steering of the irreversible worm-and-sector type with ample lock for turning in narrow spaces.



Overland Model 47 Demi-Tonneau



Plan and Side Elevation of Model 47 Overland Chassis



Section View of Planetary Gear

The engine has a bore of 3 1-2 inches and a 4 1-2-inch stroke; double ignition by means of Remy magneto and dry cells and coil is employed, and the cooling is effected by a thermo-syphon through a vertical tube radiator, cooled by a belt-driven fan.

Multiple-disc clutch is used to transmit the engine power to the gears, which are of the planetary type, giving two speeds forward and reverse operated by foot pedals; the low gear and the reverse being operated by the same pedal. The gear and rear construction are in the same housing, the rear axle being of the semi-floating type.

Two independent sets of brakes are fitted and operate on the rear wheel hubs, the internal-expansion set being actuated by a lever placed convenient to the driver's right hand and the external-contraction set by a pedal. The wheelbase of the car is 102 inches and the tread can be 56 or 60 inches at the option of the purchaser; the wheels are of the artillery type, and 32 x 3 1-2 tires are fitted to all wheels.

Included in the price of the car, which is $900 f. o. b. factory, are two gas lamps and generator, two side and rear lamps, as well as a good kit of tools and a pump.

Many New Agencies are Being Established

—J. I. Daniel, a well-known Spokanite, has taken the agency for the Velie car in that city.

—Dr. F. M. White, of Klamath Falls, Ore., now has the agency for the Cole "30" in that section.

—The Gilbert & Vaughn Implement Company, of Hood River, Ore., has taken the Chalmers agency for that section.

—The Pacific Motor Car Company, of Tacoma, the past week took over the Overland agency, formerly handled by the Avenue Garage of that city.

—The United Automobile Company, of Portland, who handles the Maxwell car, have recently established agencies at Eugene, Medford, Ashland and Roseburg, Ore.

—Kaufmann Bros. have secured the agency for the Pittsburg territory for the Imperial tires made by the McGraw Tire Rubber Company, of East Palestine, Ohio.

—Wilson & Maurer are now acting as agents for the Buick line at Salem, Ore. They now have under construction in that city a thoroughly modern and up-to-date garage.

—The Columbia Garage, Spokane, of which Hodgkins & Fosdeck are agents, have been allowed 150 Chalmers for their territory of the 1911 cars. One hundred and twenty-five of these will be 30's and twenty-five of them 40's.

—W. S. Dulmage, sales manager of the Studebaker Brothers Company auto department, of Portland, has resigned to take over the agency for the Elmore car for Oregon.

—The W. King Smith Company is now handling the National and Matheson cars and the Gramm motor truck, and is removing from 109 South State street to the corner of West Willow and North Clinton streets, Syracuse.

—T. J. Toner, head of the Motor Car Maintenance Company, New York, who handles the Grabowsky power wagons, has entered two trucks for the New York *American* commercial vehicle contest to be held October 28 and 29.

—Carl Wallerich, formerly connected with the Overland Company at Indianapolis, and later sales manager for the Haynes Company of Kokomo, has again joined the Overland selling force. He has accepted a position as special agent with headquarters at Toledo, Ohio.

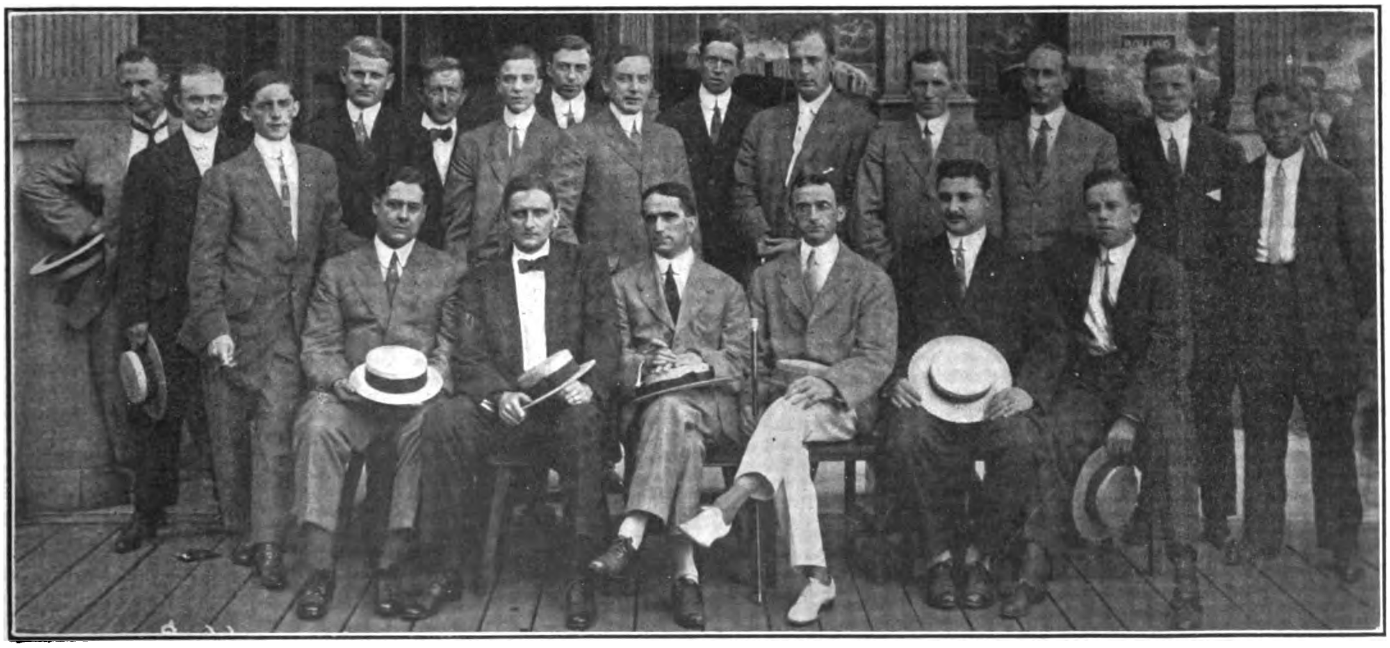
—The Metropolitan Motor Car Company, of Seattle, was last week made the Oregon and Washington Agency for the Alco car. C. S. Cummings, manager of the Metropolitan Motor Car Company, will have the agency for the entire line including taxicabs, touring and racing cars.

The Siegmund-Baylies Company, on Wabash avenue, Chicago, who have had the exclusive agency for the Rapid trucks for the past three years, have taken over the Reliance heavy-duty trucks. A new $75,000 commercial car garage and salesroom for the combined lines is in the course of construction and will be ready for occupancy about December 1.

—The Tip-Top Motor Car Company, of Hood River, Ore., is a recently organized firm to handle the Maxwell car in that vicinity, and the Lozier car in Oregon and Washington. Capt. C. P. McCan and W. T. Sleddon are the owners of the new concern. One of the many innovations introduced by Capt. McCan is the operating of a 5-8 mile track, where each purchaser of an automobile will be taught to run his car.

—During the past month an amalgamation of the Rapid and Reliance selling agencies in Kansas City has been perfected. H. C. and H. G. Shimp, formerly of the Kansas City Rapid Motor & Transportation Company, and Estell Scott, representing the Reliance Motor Truck Company, have joined forces in a new selling organization, to be known as the Rapid-Reliance Company of Kansas City.

—The Syracuse Automobile Dealers' Association has just elected John H. Valentine, president of The John H. Valentine Company, as its treasurer to succeed Harry L. Conde. The association's other officers are: C. Arthur Benjamin, president; M. W. Kerr, vice-president; George E. Messer, secretary. The organization is already busying itself with plans for its third annual show, which will be held in the Armory next March.

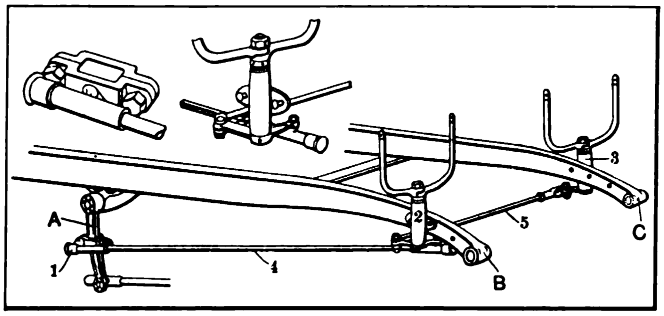


Gathering of the New York and Philadelphia selling organization of Gibney & Brother at the Marlborough-Blenheim, Atlantic City

Prominent Automobile Accessories

FOCUSES THE RIGHT SPOT

Every autoist knows the difficulty encountered in driving at night, round corners, as the rays thrown by the headlights illuminate at the opposite angle to which one is about to turn. A car fitted with the Au-Beuf brackets has its way lighted before the turn is taken, the action of the steering arm operating the brackets carrying the headlights. They can be fitted to any car, as when the equipment is sent out from the factory the bracket holders 2 and 3 are undrilled so that they can be placed in any position desired; the rod 4 is only threaded at one end and this, too, can be adapted to the requirements of any car.

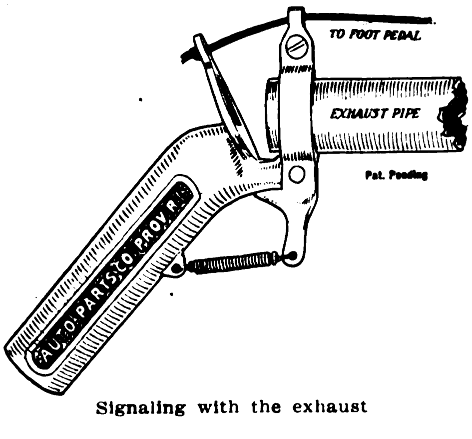


Individual view of the different parts of the headlight

Ball and socket joints with inside spring are fitted to prevent all road shocks from being imparted to the lamps, and these are made adjustable for wear to be taken up from time to time. The brackets are made to accommodate any lamp up to 9 1-2 inches. The equipment is manufactured by F. H. Au Beuf Co., Oneida, N. Y., and the price in black enamel is $25 per set.

EXHAUST WHISTLE FOR AUTOISTS

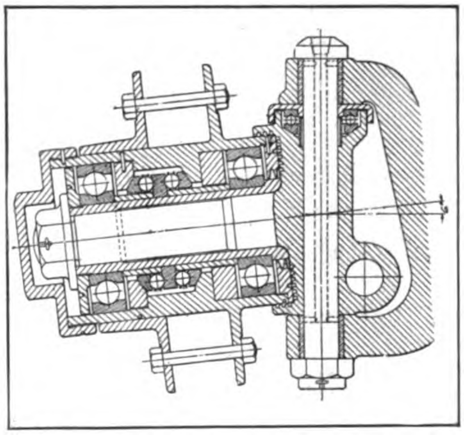
The new exhaust whistle that is being turned out by the Auto Parts Co., of Providence, R. I., is so clearly depicted as to demand almost no further reference, but it is pointed out that the method of attaching the same should prove of interest in view of the fact that the fine work that this whistle is designed to do is not hampered by difficulty in attaching the same to any make of automobile. This device is designed to warn the occupants of the highway of the approach of the automobile that has it for a part of its equipment, and, while the whistle is not intended to convey music, it is, nevertheless, a capable warning device. The design is such that clogging up is not to be considered, and back pressure is eliminated. The price of this device is $3.50 through dealers or direct from the maker.



Signaling with the exhaust

HESS-BRIGHT HUB BEARINGS

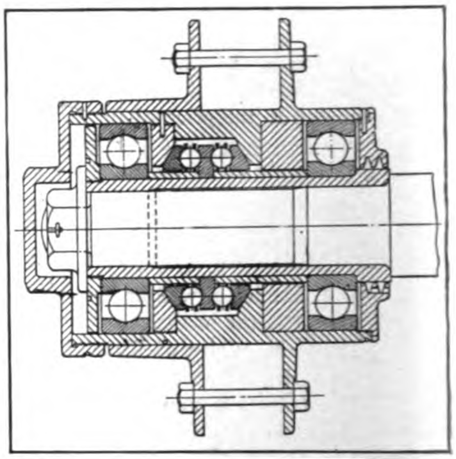
The strains and stresses imposed on the bearings of a heavy 3 1-2 to 5-ton truck are different from those on a touring car in so far that the super weight is more and center of gravity is often considerably higher. The Hess-Bright Manufacturing Co. has designed a hub to be used for either front or rear wheel that takes all radial loads and side thrusts.



Front axle hub, showing Hess-Bright method of fixing radial and torsion bearings

Both radial and thrust bearings are mounted on a sleeve inside of the hub; the inner races of the radial bearings and the center plate of the thrust bearings are clamped between the large flat nut, distance bushes and a shoulder on the sleeve.

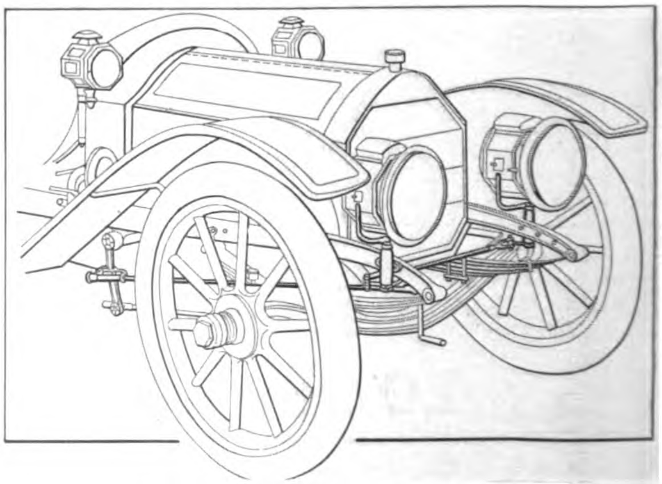
The wheel may be slipped off or on in the same manner as a plain spindle bearing without exposing the ball bearings to the surrounding dirt and grit while handling the wheel and without loss of lubrication or need of recharging. Taking into consideration the conditions of unskilled and rough labor incidental to truck operations this feature is an advantage.



Rear axle hub, showing Hess-Bright method of fixing radial and torsion bearings

The sleeve is secured to the axle by a hexagon nut, which is large enough to act as a locknut for the spindle end nut. A loose floating bush having a running fit is inserted between the inner radial and the thrust bearings. Protection from water and dirt is obtained by recessing the hub, and cutting a series of grooves which are filled with grease before the wheel is slipped on.

The use of the ball thrust bearing in the pivot assures greater ease in steering and in heavy truck work this is very tiring. It will be noticed that the dish of the front wheels is 6 per cent., whereas the customary allowance for touring cars is somewhat less. The easing up of the labor of steering big commercial vehicles will result in satisfied operators and in more work.



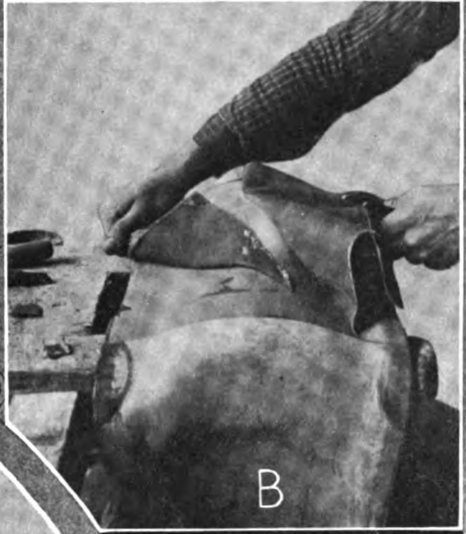
Au Beuf automatic headlight brackets for automobiles—headlights controlled by the steering wheel

Vol. XXIII New York—Thursday, October 27, 1910—Chicago No. 17

The Automobile

Care and Repair of Tires

Stripping Outside Rubber for a Complete Retread



Ripping Off Inside Layer of Canvas

Stripping Canvas from Section to be Repaired

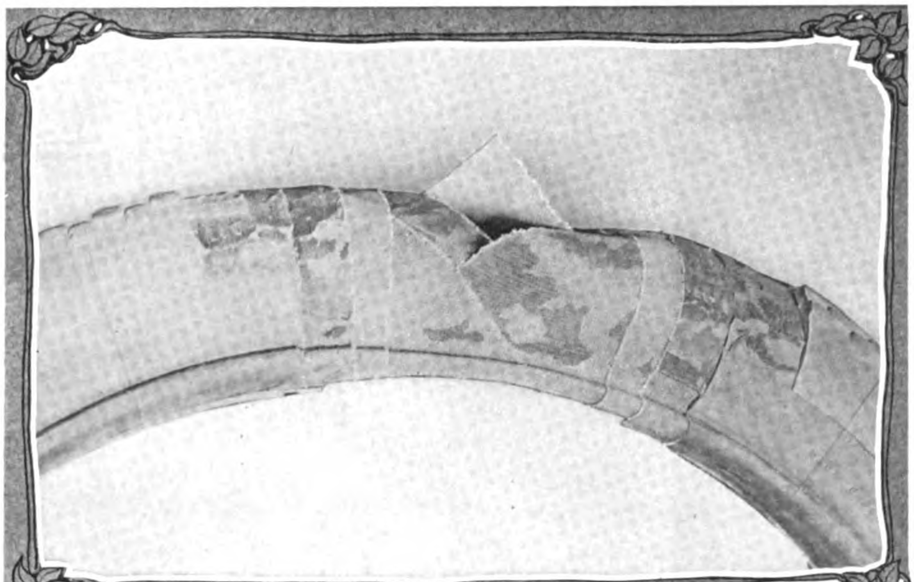
UNLESS some genius with an inventive mind will come to the rescue of the automobile business with a type of wheel that will commercially supplant rubber tires, assuming that tire makers are doing the best that they can, it is much to be feared that the statement of a man high up in the automobile business is founded on truth. This keen visioned man of automobile affairs said: "Counting cost in the long run, the automobile is the tail and the tire is the dog; the question is, Will the tail wag the dog?" If the right kind of a man with a creative mind that succeeds in commercializing the kind of a wheel that will not depend for its efficacy upon pneumatic tires, the tail will not have to wag the dog—it can be cut off.

Automobilists are not in a position to await the coming of the "Wellington" who is to give battle and subdue the "Napoleon" who is perched so conspicuously upon the throne of the automobile empire; their needs are immediate and pressing; millions of dollars' worth of automobiles are in daily use and more millions of dollars' worth of tires must be kept in a state of good repair in order that their life may be conserved for the greatest possible length of time in the face of great discouragement.

If it is true that tires, as they are now made, are up to the highest obtainable standard in point of material and workmanship, then, in the absence of something better, it devolves upon automobilists to make up the deficit, interjecting the requisite measure of caution and care in order that when the balance is struck the cost of maintenance of the automobile, as a whole, will not exceed the value of the advantages derived from its use.

The immediate and pressing need, in view of all the circumstances, is coupled with the care and repair of tires. Were an autoist to be told that he does not realize the seriousness of the situation, he would scoff at the bearer of such stale news, but the fact remains that the editor of THE AUTOMOBILE stood on the corner of Forty-second street and Fifth avenue for just one hour on October 20, during the passing of 46 automobiles, 29 of which were running on pneumatic tires that were not in a good state of repair.

Of the 29 automobiles referred to, 24 of them were driven by chauffeurs, and the conclusion reached, after considering this phase of the situation, was that automobilists who drive their own cars do pay some attention to the care and repair of tires, but that chauffeurs are more interested in collecting the commission on new tires than they are



D—Section to be retreaded showing different layers to be filled up to

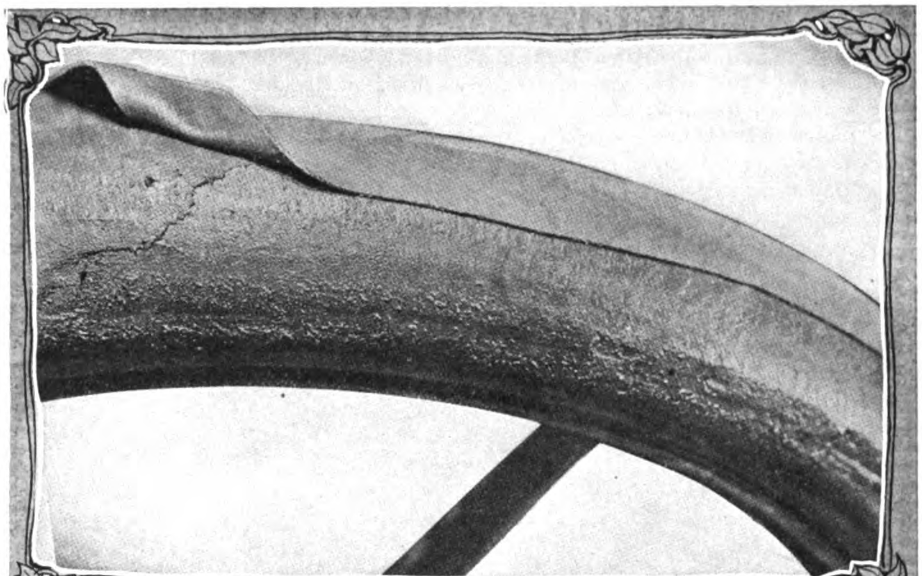
F—Solutioning part to be repaired

G—Roughing up tire before solutioning

in prolonging the life of the tires in use.

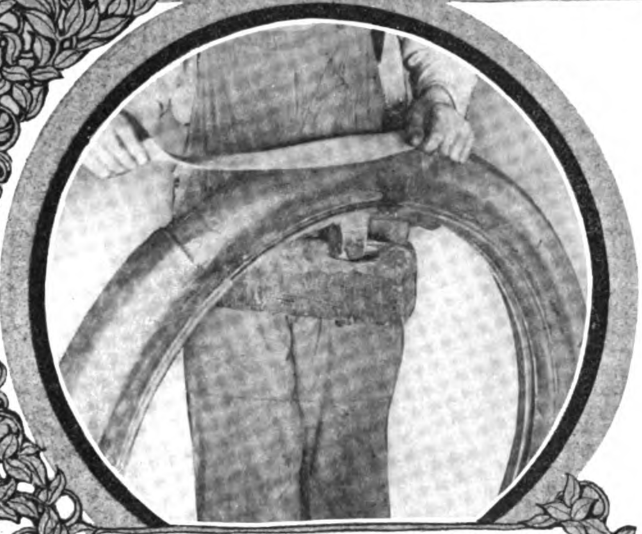
"An ounce of prevention is worth a pound of cure." This old and trite saying never applied to anything with such great soundness as it does to the tire problem. This being so, the first move in the application of the principle demands the instant dismissal of the chauffeur who is not satisfied with his position and his salary, and who fastens his fangs upon the man who employs him, aided and abetted by the tire vendor who is so lacking in business acumen and common honesty as to put himself and his business under the shadow of a crime.

In talking about the tire problem to an automobilist who keeps several cars in commission, he related an incident that bears fittingly upon the points that are here to be made, when he said: "My chauffeur when he brought me to the office this morning asked me for permission to take the car up to his place of abode in upper Harlem in order that he could attend to one of his private affairs. I refused him permission to do so and pointed out that it was far cheaper for him to take a trolley car, leaving my automobile in the garage. He did not seem to appreciate the fact that a menacing tire bill, under the best of conditions, is increased by every foot that an automobile makes; he was spending my money which made a great difference with him."

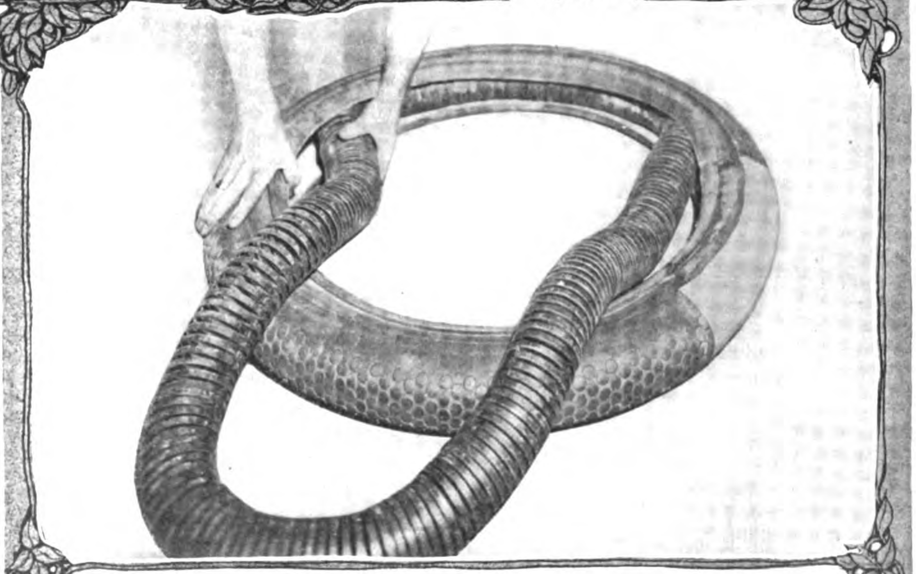


H—Solutionized cover having a strip of rebuilding fabric laid in place

J—Semi-cure process using a band press system



I—Laying four-ply unvulcanized gum on part to be repaired



K—Inserting coil spring before wrapping

The owner of an automobile who supports a chauffeur if he declines to have his automobile worn out in the service of his majestic employee is dubbed a "tight wad." Some owners are so thin-skinned that they wince at the appellation, overlooking the advantage derived, forgetting, for the moment, that a "tight wad" prefers to employ the character of chauffeur that is satisfied with an honest living and insists upon having his tires maintained in a state of good repair, and being wise, makes his own purchases, not only of real estate, but of tires as well.

Every business man knows that there are grades in quality of every commodity, and there is no reason for believing that tires are an exception to this rule. The first principle involved in the purchase of anything demands that the purchaser represent himself, but if there are reasons why he cannot do so, the second principle demands that he appoint an honest agent.

It is necessary to consider all these preliminary attending features in the discussion of the care and repair of tires for reasons as follows:

(A) Superior grades of tires will last the longest in a given service.

(B) If repairing is neglected more or less, the better the quality of the tires, the less marked the effect of abuse will be.

(C) The efficacy of repair depends absolutely upon the quality of material of which the tire is made.

(D) If the fabric of the tire is inferior, a "blow-out" will result and patching a tire that is so poor that it will blow out is a futile undertaking.

(E) If the rubber compound is lacking in cementing qualities, it is useless to try to make a repair, since the new work will not adhere to the old.

In measuring the value of prompt and skillful repair work, in view of the above considerations, the first real effort in the direction of repairing comes in the purchase of the tires. If the price lists are all alike, and the discounts are identical, it remains to discriminate between the different grades of tires and purchase the kind that will (a) last the longest in a given service and (b) submit to the repairman's manipulations most efficaciously.

Having purchased tires that will last the longest in the first place, and lend themselves to repairing operations with greatest facility, the real questions of maintenance must then be coped with, and in view of the cost of tire maintenance, the same discriminating care that is given the watch in the automobilist's pocket will bring an equal measure of result with the tires.

Remembering that destructive wear comes with increasing speed rather than with the weight that has to be borne by the tires, considering also that the road condition has a marked effect for good or ill, it remains to defer the day of necessary repairing in the ways as follows:

(A) By using the automobile as sparingly as possible, traveling the long way around rather than by short cuts, if good road conditions can be so had.

(B) By keeping the speed of the automobile down to reasonable limits at all times, remembering that the wear and tear will be multiplied by four if the speed is doubled; in other words, whatever the wear and tear might be at 20 miles per hour, it will be four times that amount at 40 miles per hour.

(C) By watching the road condition rather than to maintain some predetermined speed as measured by the speedometer.

(D) By driving slowly when the going is rough, dropping down to low gear when the top dressing of the roadway is covered with loose broken stone.

(E) By remembering that the way to cut rubber is to wet it, not forgetting that sharp stones will cut the rubber thread of the tires with relative ease on a wet day.

(F) By keeping the tires fully inflated, with never a fear of overinflation, due to any effort that can be brought to bear, through the use of a hand pump and the exertion of an autoist.

(G) By keeping out of car tracks (absolutely), with never a thought of treading into frogs and crossings under any circumstances—the frayed-out metal at these points is extremely sharp and will cut like a razor.

(H) By remembering that "flywheel effect" has a pronounced bearing upon tire life—the larger the diameter of the road wheel and the faster it travels the greater will be the flywheel effect.

(I) By going around corners slow enough to prevent skidding.

(J) By applying the brakes gradually.

(K) By letting in the clutch softly.

(L) By maintaining correct parallelism of the road wheels.

(M) By disregarding what the pressure gauge says, if the respective tires indicate that they are not equally blown up—the same roundness of section should obtain for each tire at the point of road contact.

(N) By substituting larger section tires, if those in use will not carry the load without showing flexure when they are fully inflated—no amount of pressure will suffice to make the tires stand up under the work if they are too small.

(O) By washing the tires with tepid water, rendered soft by castile soap, every time the car comes in off the road and inspecting the tread at every point, looking for cuts or abrasions, with the understanding that they will be fixed before further use.

(P) By keeping the garage floor scrupulously clean, with especial reference to lubricating oil, making sure that no lubricating oil whatever is permitted to remain on the tires.

(Q) By protecting the tires from applications of gasoline or other hydrocarbon fuel.

(R) By removing the tires at reasonable intervals and cleaning the rims, after which re-enamel them, thus preventing rust formations from attacking the fabric.

(S) By making sure that the inner tubes are of the right size.

(T) By guarding against kinking or overlapping of the inner tubes.

(U) By adjusting the clips so that they will not bite the inner tubes.

(V) By using talcum copiously as a tire lubricant, making sure that every portion of the surface of the inner tube is well coated over.

(W) By scrutinizing the inner walls of the outer casing and removing every rough zone, taking particular notice as to whether or not nails or other puncture producers are not projecting through ready to puncture every inner tube that is put into place.

(X) By exercising care in putting on tires, making sure that the tire irons do not bruise the inner tubes and fray the beading of the outer casings.

(Y) By keeping the tires out of direct sunlight, away from dry steam heating and in a cool, well ventilated room under conditions of subdued lighting—when on the road if the car must stand for a time select a shaded place.

(Z) By jacking the car up off the floor when it is not in use, thus taking the weight off the tires and letting off a little of the tire pressure, making sure, however, that the car is not rolled around until the tires are fully inflated again.

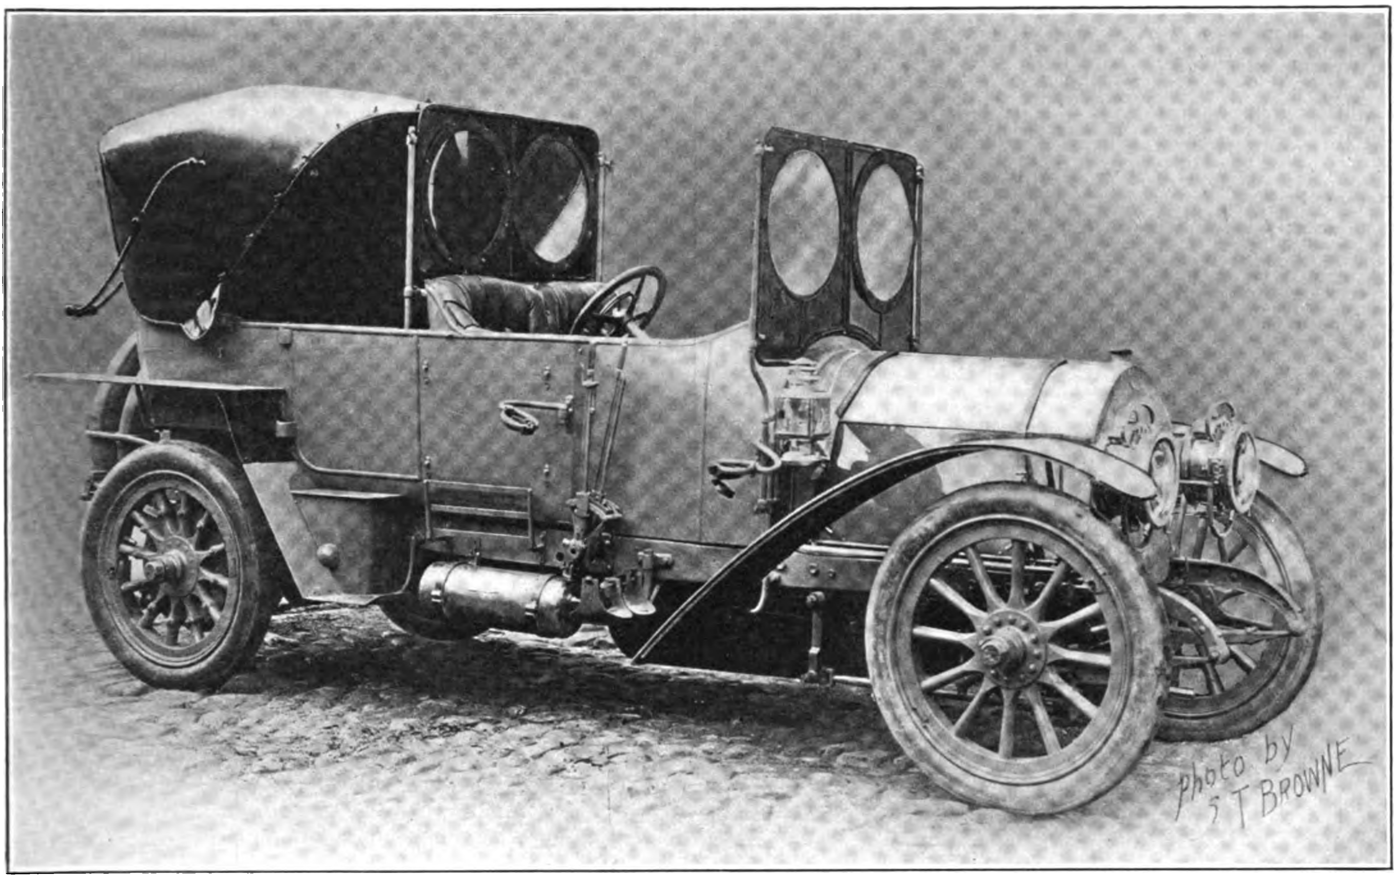
Copy the Professional in Making Repairs

Having exercised every precaution as above set down, taking advantage of experience, not relying upon these suggestions alone, it still remains for the automobilist who proposes to make the best fight he can in the face of adverse conditions to put himself in possession of the best possible information in relation to repair work, copying the methods of the professional up to the limit of unprofessional facilities, making up in added skill and greater care for the absence of the more perfect methods, calling upon the repairman to perform the truly difficult tasks rather than to display the distinguishing characteristics of the penny-wise and pound-foolish.

The series of illustrations that are offered in connection with this article were taken at the Knickerbocker Tire and Repair Company's plant, and depict the methods in vogue in professional repair plants where tires are handled in a large way. Each step from A to Z of the whole process is shown, from the healing of a simple wound on the thread of a tire to the stripping of a carcass and rebuilding from the ground up.

Among the Makers

WINTER AUTOMOBILING; MOON CAR FOR 1911; FRANKLIN AIR-COOLED AUTOMOBILES; EXPERIENCES OF A DEEP-SEA HACKMAN, ETC.



THE BODY MAKES THE APPEARANCE OF THE CAR—A ROTHSCHILD STUDY

WINTER automobiling, rather than to put the car out of service, is becoming the regular order of things. There is no longer any reason for desiring to lay up the car for the winter. On the other hand, since the going is naturally the worst when the weather is inclement, it stands to reason that the best work can be done, counting from the viewpoint of real utility, when the snow is on the ground, and the wise owner now saves himself rather than put his automobile out of use at the very time when it will be of the greatest value to him. Just why automobiles are now in fettle to do winter work on a basis that is more in keeping with the needs is difficult to explain, excepting that larger diameter wheels, more power, greater flexibility, superior material, exacting workmanship, and last, but not least, types of body work that protect the occupants from wintry blasts, are important factors. Saving the man rather than the car, is a natural and timely thing to do.

Moon Cars for 1911

MODEL 30 IS RETAINED SUBJECT TO REFINEMENT; MODEL 45 REMAINS THE HIGH-POWERED STANDBY; IMPROVEMENTS ARE MADE ALL ALONG THE LINE

ANNOUNCEMENT is made of the Moon line of automobiles for 1911, and advices from the Moon Motor Car Company, of St. Louis, Mo., lend substance to the understanding that the Moon 1910 automobiles had arrived at a level, from the point of view of standardization, to warrant the company in staking its future upon them, subject to such changes and refinements as an efficient engineering corps at the company's plant would necessarily desire to incorporate remembering that the whole procedure should be by way of an evolution rather than to depart from well-known standards that are giving satisfaction, hoping, perchance, that something new and untried will accomplish that which has never been done before.

The Model 30 car is offered to the Moon clientèle with five body options, as shown in the tabulation, with prices ranging from $1,500 for the Touring Car, and Toy Tonneau, as well as the Roadster, to $2,750 for the Landau, with a Coupé intervening at $2,250.

The Model 45 car is offered in five options, including the

Touring and Toy Tonneau at the same price, while the foredoor type and Torpedo body cars are priced at $3,100 each, and the Limousine sells at $4,000.

The Model 30 car has 114-inch wheelbase and standard tread, while the Model 45 car has 121-inch wheelbase and standard tread. The approximate weight of the Model 30 car is 2,650 pounds, and the tire equipment is 34 x 3 1-2 inches. The Model 45 car weighs about 3,100 pounds, and the tire equipment is 36 x 4 inches.

The most noticeable improvement in the motor of the Moon "45" is in the method of driving the magneto and water pump. These are now located at right angles to the crankshaft and driven with one gear off the vertical camshaft. This change has allowed the discontinuance of the pump gears formerly employed. The lubricating system has been retained in precisely the same arrangement as on former models for the past four years, the crankshaft being drilled as heretofore. The force feed lubricator, instead of being located on the dash and driven by an extension of the camshaft, is now operated by two spiral gears, which leaves the dash perfectly plain, except for the single sight feed. The exhaust manifold has been remodeled so as to leave fewer bends and angles to impede the progress of the exhaust gases.

One most noticeable change is the method of drive and rear spring sus-

pension. Three-quarter springs are used in the rear instead of full elliptic as before, and the axle drive is direct through them to the frame, doing away entirely with the drive rods and the familiar V-type of drive with the ball and socket, which was so long a Moon characteristic. The muffler is no longer carried on the rear of the frame, but is hung longitudinally underneath the body. A dust shield takes its place in the rear.

The touring car bodies for the "45" have been given two inches more room in the tonneau and the entire tendency has been in a modification of both the straight line and convex type. Fore-door bodies and torpedoes have been added to the selection of bodies.

Jump spark ignition is employed, with dry cells and a Remy magneto used in dual combination with a single unit coil and a single set of spark plugs.

In the Model 30 car ignition is by Remy magneto, with a coil and dry cell auxiliary, whereas in the Model 45 car the ignition is by Bosch magneto, using a dry battery for the secondary source of electrical energy. Both types of motors are water-cooled with a centrifugal pump for circulating the water, and the radiator of the Model 30 is of the tubular type, whereas the radiator of the Model 45 is of the honeycomb type. Lubrication is by splash in the Model

Fig. 6—Moon model 45 with the fore-door type of body

30, and with a mechanical system in the Model 45. The general appearance of the Model 45 fore-door type of car is shown in Fig. 6, and comparing this model with the fore-door type of body on Model 30, as shown in Fig. 7, it will be possible to realize that there is a certain standard of design and appearance that is maintained throughout the work done by this company.

In order to understand the general scheme of design it will be feasible to examine the stripped chassis of the Model 30, as shown in Fig. 5, in which the radiator R1 is located in the plane of the front axle, and the four-cylinder T-type motor M1 is placed far enough back of the radiator so that the air, as it passes through the interstices of the same, is unimpeded and flows down, due to the displacing action of the fan in the flywheel F1 within which the multiple disc clutch C1 is nested, and the power, as it is delivered by the motor, and controlled by the clutch, is transmitted therefrom through the shaft S1 to the propeller shaft in the tube T1, thence to the transmission gear G1 to the differential gear in the housing H1 of the live rear axle. The power is weighed out by the differential gear and delivered to the jackshafts within the axle tubes T2 and T3, thence to the rear wheels. The chassis frame, with its side bars B1 and B2, is of the channel section, suitably fashioned of a proper grade of steel, and the flanges are widened from the point of narrowing at the dash, tapering off toward the back, thus affording strength where it is most needed. While it is the aim to secure great rigidity of the chassis frame, not only by the selection of the material and the liberal section employed, but by the use of a substantial cross bar C2, and at the point of support of the motor, it is also the plan to maintain great flexibility of the relating members, partly by the use of a well-contrived universal joint U1, and by maintaining a straight line relation of the members and true turning centers.

Referring to the motor of the Model 30, Fig. 3 shows the left-hand side of the same with a magneto M1 on a shelf S1 back of the centrifugal pump P1 with a shaft S2 used in common for driving, the same receiving its power from a pinion in mesh with the half-time gears, all of which are encased in the housing H1. The lubricating oil is stored in the bottom half of the crankcase S3, and is circulated by means of the pump P2, the latter being driven by the shaft S4. Water enters the centrifugal pump through the fitting F1, and leaving the pump through the fitting F2 enters the two pairs of cylinders at the flanges F3 and F4, leaving the cylinders at the top through the fittings F5 and F6, there being a flexible connection C1 between

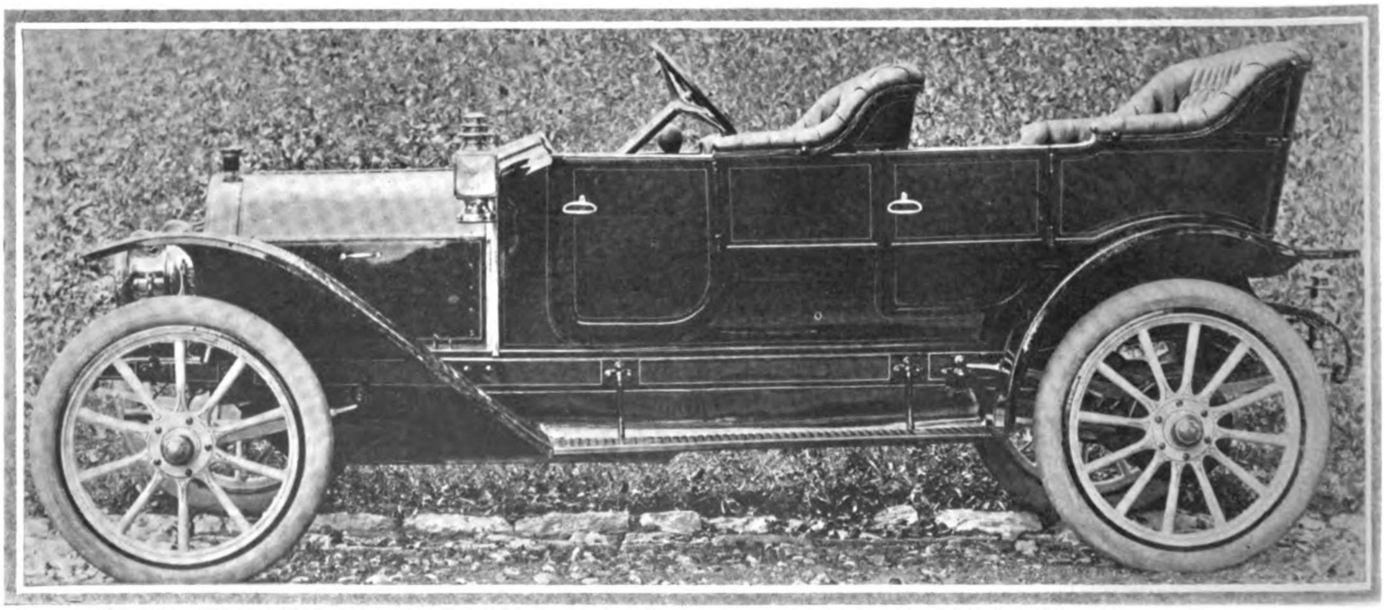

Fig. 7—Model 30 with the fore-door type of body

the fittings, and a second flexible connection C2 at the junction of the fitting F6, and the fitting leads to the radiator. The exhaust manifold M2 is shaped with an easy bend B1, and is so designed that the fastenings M3, M4, M5 and M6 are readily gotten at for purposes of assembling, tightening up, or disassembling. The flywheel F7 is of large diameter, and it is properly marked off, so that the autoist may check the timing of the motor at will, and the motor is suspended on the chassis frame by means of drop-forged arms A1 and A2, so that the weight of the motor and the gyrations of the flywheel are adequately cared for, without stressing the metal of the crankcase.

Glancing at the right-hand side of the motor, as shown in Fig. 1, it will be observed that the carbureter C1, of the Schebler type, is in an accessible position, remote from the sparking equipment, and is connected to the two pairs of cylinders C1 and C2 by a standpipe P1 and a cross-connection C3. This side of the motor shows the valve mechanism clearly, and the guides G1, G2, G3 and G4 are designed to afford a long bearing, maintain the right relation of the parts, and perform noiselessly. This being the intake side of the motor, the spark plugs are located herein, coming just above the intake valves.

Referring to Fig. 4 of the front end of the motor, the half-time gears G1 and G2 are keyed onto the cam shafts C1 and C2, and are driven by the pinion P1, which is keyed onto the crankshaft C3. The magneto M1 is driven by the pinion P2 through the shaft S1, taking its power from the gear G2.

The rear end of the "30" motor is shown in Fig. 2, bringing into view the fan blades F1, of which there are six, joining the flywheel rim R1 to the clutch housing H1, showing the six bolts B1, by means of which the flywheel is flanged to the crankshaft.

This illustration also shows the accessibility of the magneto M1, and affords a better view of the drop-forged I-section cross-arms that serve as a support for the motor, they being fastened to the chassis frame with overhanging lips L1, so that the load is carried in shear by the section, and the holding bolts are relieved of this responsibility.

There are many other nice ramifications that might be studied in connection with the Moon models, some of which, however, can only be brought out by an examination of the working drawings, or if the cars are inspected. The tabulation given enumerates the remaining general characteristics not herein discussed.

Franklin Product and Practices

AIR-COOLED MOTOR AND ACCESSORIES; DEPICTING METHODS OF MANUFACTURE; TREND IN AIR-COOLED MOTOR WORK

UNUSUAL interest is centered in the methods in vogue in the plant of the H. H. Franklin Manufacturing Company, of Syracuse, N. Y., due to its close adherence to a definite standard, with its attending and unqualified success. This plant has been devoted to the manufacture of air-cooled motors from its inception; it has never departed from its chosen class of work, and the evolution of the air-cooled motor in America will be best appreciated by observing the refinements which will be found in the 1911 Franklin motors, and studying the methods of manufacture simultaneously. The output of the plant for the immediate future will comprise four models in the line of open cars, two of which will be equipped with six-cylinder motors, and the remaining models will have four-cylinder motors. These models are known in the Franklin literature as H, D, M and G, and their horsepower ratings are 48, 38, 25 and 18, respectively.

The six-cylinder type of motor, as will be found in models H and D, is depicted in Fig. 13, showing the motor with its cylinders, C1, C2, C3, C4, C5 and C6, of the air-cooled type with vertically disposed flat steel gills, surrounded by air jackets, left open at the top and bottom so that the cooling air is drawn in over the hottest zones at the top of the respective cylinders and passes down in equal quantity for each cylinder, sweeping over the surfaces of the gills, passing out by way of the squirrel cage air propeller P1, as shown in Fig. 17. A more precise detail of the design of the cylinders will be found in Fig. 14, presenting two of the cylinders of the four-cylinder motor during the process of erection. Referring back to Fig. 13 of the exhaust side of the motor, it will be observed that after the air passes into the jackets of the respective cylinders it comes out below into the space surrounding the motor case in the lower extremities of the cylinders, and the arrangement of the partitions P1, P2 and P3 is such that when the bonnet is put on, the same resting on the chassis frame F1, the space below P1 is rendered tight, and all the air that is moved by the propeller as shown in Fig. 17 must pass down through the jackets of the cylinders, and since the openings are equal in point of arc for the respective cylinders, the supply of air is regulated so that each of the cylinders is maintained under constant conditions of cooling. The exhaust manifolds M1 and M2 are connected up so that the exhaust from the cylinders is first into the manifolds M3 and M4, thence to the manifold M1, but when the pistons travel to a point near the bottom of the stroke, the auxiliary valves V1, V2, etc., there being one for each cylinder, are open, and it has been found by test that over 70 per cent. of all the exhaust passes out through these auxiliary valves, thence to the manifold M2, from there to the muffler, through the muffler piping, and away to the atmosphere from the muffler. Observation leads to the definite conclusion that the main exhaust valves in the heads of the cylinders are maintained well below the point of destructive distillation of the lubricating oil used, due to the fact that the greater portion of the heat passes out through the auxiliary valves, and in order that the latter will serve under such conditions efficaciously, nickel steel heads are used, whereas in the main exhaust valves a type of carbon steel is employed similar to that used in the inlet valves.

There are incidental gains that must be ascribed to the plan involving auxiliary exhaust valves; the heat is distributed uniformly over the cylinders; distortions due to differences in temperature are obviated, and the combustion chamber is maintained at a constant desired temperature, which has a marked effect upon the power delivered by the motor, due to the fact that the weight of mixture taken in per suction stroke.

Referring to Fig. 19 of the intake side of the motor, the carbureter manifold M1 connects, between the carbureter and the distributing manifold, with its branches M2 to the right and M3 to the left, connecting around both ways to M4, with connections leading therefrom to the respective cylinders. The magneto M5 is located inside of the steering gear G1, somewhat below the level of the chassis frame F1, and the wires W1 leading from the magneto are distributed to the respective spark plugs through the tube T1. The same care is taken to control the direction of travel of the cooling air in the intake side of the motor as is observed in the management of the same on the exhaust side as shown in Fig. 13. The valves are actuated by a system of rocker arms, they being in the heads of the cylinders, and the valve springs are placed in relatively cool situation so that they retain their tension permanently. The rocker arms and the method of lifting are clearly brought out in Fig. 13, and the springs show in the greatest prominence in Fig. 19.

Referring to Fig. 14, it is shown how the gills G1 are stopped off above the flanges of the auxiliary exhaust ports P1 and P2, but the gills extend down well below the auxiliary exhaust ports excepting where they are stopped off as a matter of necessity. The cylinders are cast individual, and are faced off so that they rest on the finished table T1 of the crankcase, and are held in place by studs S1, of which there are four for each cylinder. The crankcase is made in one piece, and one side is faced off F1 to accommodate the cover for the holes H1, H2, H3 and H4, through which access is gained to the main bearings M1 of the crankshaft, and the connecting rod bearings C1 as well. The crankshaft C2 is inserted through the end plates E1, which are held on by studs S2 so closely spaced that the seam is made oil-tight. These end plates carry the main bearings M2 and M3, they being sufficiently long to take the extra load imposed. There is one additional feature to be noted in connection with the end plates. They are cast integral with the motor arms M4 so that the strain due to the weight of the motor and the contortions of the chassis frame is carried by these arms, rather than by the aluminum crankcase.

The flywheel effect is varied between the four and the six-cylinder motors, being more in the four-cylinder types in order to afford the requisite equalizing moment, and a reduced value in the six-cylinder motors in view of the overlapping of the torque, and back of the squirrel-cage air propeller P1, Fig. 17, the multiple-disc clutch is assembled in its housing H1 with a suitable number of discs D, including a thrust block made up of thrust plates P2 and P3, and a plurality of balls in a retainer plate P4.

The general appearance of the carbureter is shown in Fig. 10; it is of the Franklin design. Referring to Fig. 15, attention is called to the nozzle standard N1, with three inserted nozzles N2, N3 and N4, through which the gasoline passes into the surrounding depression chamber, which is of the modified Venturi-tube type. The butterfly valve V1 controls the mixture en route to the motor, but in order to regulate the ratio of gasoline

to air an auxiliary air valve is utilized, as shown in Fig. 16 at A1. This valve is of the automatic type, admitting air in response to the suction of the motor, with a means available for regulating the action of the valve, utilizing springs S1 and S2, the tension of which is fixed by manipulating the knurled thumb nuts N1 and N2. The flow of gasoline from the supply pipe P1 is into a filtering chamber C1, thence through the filter into the float bowl B1, under the control of the float F1, lifting the needle off its seat S3 when the gasoline falls below the level of the nozzle orifice by a predetermined amount. As a further means of regulating the flow of gasoline, the needle valve V1 may be regulated by means of the tumble shaft T1 with a universal joint U1. When it is desired to regulate the flow of gasoline this needle valve V1 is screwed down against its seat by turning the shaft P1, the latter extending up to the dash, with a handle to operate it.

The magneto, which is of the Bosch type, is shown in Fig. 12, disclosing a method of construction that obtains in the Franklin plant, utilizing the unit idea of assembling. The magneto M1, with its extension shaft S1, is driven by the pinion P1, under the control of a governor G1, assembled in the spider S2. On the 18-horsepower engine the spark is fixed, but the remaining models are equipped with a governor, the function of which is to automatically advance the spark, consistent with the requirement, in view of the speed, at any given instant.

The transmission gear as shown in Fig. 11 is of a light but stout construction, using special nickel steel cut from hammered bars for the gears and spindles, and subject to a specific heat-treatment to afford the requisite wearing qualities. A wide-faced brakedrum with external contracting bands B1 and B2 is included in the transmission unit, and Fig. 18 shows the details of the clutch and the method of taking up for wear with great clearness. One member of the universal joint U1 is nested within the brakedrum B, and the exterior of the crankcase C1 as shown affords an idea of the compactness of the transmission unit.

The tabulation as here offered affords specific information in relation to the respective models.

Stronger than the Shells

"OLD WALT," THE DEEP-SEA HACKMAN, TELLS WHAT HE LEARNED ABOUT THE SURE-THING MEN WHO RACE AUTOS ON THE BUSH CIRCUIT

"'TIS better to hev run and win than never to hev run at all," hummed Walter Thornton O'Brien, better known as "Old Walt," chauffeur and mechanician of one of the most popular deep-sea-going hacks along the White Way. "Old Walt" was indulging in a bit of double-handed work in front of Flaherty's free-lunch counter and paused between mouthfuls to moralize upon the general situation, particularly as it applies to the automobile.

Having finished all the lunch he thought the barkeep would allow him to consume, he stepped back from the counter and nodded toward Flaherty's end of the bar.

"What's that you're singing?" inquired Flaherty, wiping his hands on the bar towel and settling himself to hear the words of wisdom that he was sure would follow the opening.

"It's just a little song that's making a hit up the line," answered Walt. "I heard a fellow singing it to-night and I ast him the same question you ast me."

"What did he say?" asked the proprietor.

"Why, the fellow was one of those automobile guys and I nailed him at the station. He had a grip full of kale and had just landed from a train. He was happy about something and the first thing he sez to me is: 'Hey, kebbie,' sez he, 'drive me around the park a few times; I wants to stack up this junk.'

"'Must be pretty good in the Bush League,' I sez, and climbs on the box.

"I had taken him two miles when he tells me to pull up in front of Grogan's side door and asts me to have something. We get out and after a round or two he sez:

"'It's a measly shame to take the money. I'm J. Wilfred Wishington, the automobile race promotor,' he sez, and swells up his chest.

"I simply looks at him and feels nervous about the fare. You know, Flaherty, what a bum finish I made last year trying to collect from one of them promoters over on Long Island. I had to black his eyes and break his nose and two ribs before I found that he had been joy-riding without the necessary funds. I was almost tempted to use force in that case, but durn my tender heart, I just couldn't bring myself to it.

"'We certainly slipped one over,' chuckled my fare. 'Y'see the bush racing game is a frame-up most generally. All y'have to do is to get a sanction from the Three B's and invite the natives to participate. Then when some of the smart Alecs enter, all y'have to do is to slip one of your ringers into the event and there ain't a living chanct for the Alecs to collect any prize money. The durn fool public ain't wise yet, although the game is a little tougher than it was last year. They came pretty near handing us one a while ago, though. Y'see some jealous gink wants to annoy us and he slips in a big, strong car in the biggest race we've carded. He has it jiggered up like a dope-horse and disguised so that we didn't suspect nothing until post time. Our car was about twict as big as anything in the race except the ringer, but after the start we found without no sense of glad surprise that somebody had been trifling with our "extra agent of oxidation." In fact, we found that the agent had been slipped into the tanks of the ringer instead of into those of our car.

"'Well, they was off in a cloud of dust and the ringer shot out in front and led us for eight miles and going easy. It was a ten-mile race and we had to do something quick. So I take an axe-handle and runs up the stretch about to the last eighth pole and waits for the ringer.

"'I waved to the ringer to stop and he like a chump done so. I told him he was suspected of using some unfair means of giving his mixture a kick and held him until our mut came along and got such a lead on the last mile that the ringer didn't have a chanct.

"'The ringer was a sore butcher, but we needed the money and it would never do to let anybody get away with anything; which, by the way, they did not."

"Well, but what's the answer?" inquired Flaherty as Walt stiffened up and accosted a newcomer, evidently in a hurry, with: "Keb, sir?"

Saturated Mixtures of Air and Vapor

Primarily the weight of any vapor that air will hold will depend upon the temperature to which it is raised, and the higher the temperature the greater will be the volume, and the lower the weight of the air. A state of saturation will follow for each temperature, and while the volume of air will increase with increasing temperature, thus decreasing weight, even so, the capacity of the air for vapor will increase. The weight of vapor per hundred pounds of air, at different temperatures, may be determined in the manner as follows:

$$w = \frac{62.3 \times E}{29.92 - E} \times \frac{29.92}{p}$$

When,

E = elastic force of the vapor at the given temperature, in inches of mercury;

p = absolute pressure in inches of mercury, = 29.92 for the pressure of the atmosphere as ordinarily taken;

w = weight, in pounds, of vapor, for complete saturation, at the given temperature, at which the elastic force is determined.

The vapor carrying ability of the air is of the utmost importance in connection with carburetion, since, if the air is not in a state to hold vapor of gasoline to the desired extent, the results will fall off accordingly. The accompanying table will serve to render comparison potent, as well as to clearly indicate the reasons why atmospheric influences do affect the performance of cars in practice.

CAPACITY OF ATMOSPHERIC AIR FOR VAPOR AT DIFFERENT TEMPERATURES

Temperature in degrees Fahrenheit	Pounds per cu. ft. dry air	Pounds of vapor in one pound of air	Weight in pounds cu. ft.		
			Saturated Air	Vapor in air	A|V
32	0.0807	0.00379	0.0802	0.000304	263.7
42	0.0791	0.00561	0.0784	0.000440	178.18
52	0.0776	0.00819	0.0766	0.000627	122.
62	0.0761	0.01179	0.0747	0.000881	85.
72	0.0747	0.01680	0.0727	0.001221	59.5
82	0.0733	0.02361	0.0706	0.001667	42.3
92	0.0720	0.03289	0.0684	0.002250	30.3
102	0.0707	0.04547	0.0659	0.002997	22.

The ratio A to V clearly indicates the rate at which the air changes in its ability to sustain a vapor, and, too, the effect produced on the weight of vapor per cubic foot of the air.

A Timely Tip to the Tyro

When buying a car, insist upon magneto being fitted; there is nothing more annoying than to have to stop on account of a battery being run down. When the magneto is fitted there is often a secondary ignition one can fall back upon, and a good way to see that this is always in proper order is to light the side lamps by electricity and kerosene as well. The driver will have to see that the batteries are charged for his lights and at the same time you will be able to use the current for starting and in case of trouble with the magneto.

Engineering Section

DEVOTED TO THE DISCUSSION OF ENGINEERING PHASES OF AUTOMOBILING, INCLUDING DESIGNING AND CONSTRUCTION FEATURES OF PRODUCTS, AND INFORMATION TO AUTOISTS

ILLUSTRATING METHOD EMPLOYED IN BROACHING SQUARE HOLES IN SPROCKET WHEELS AND GEARS AT WOODS PLANT

WE are given to understand that God made man in the exact image of Himself and that nothing is hard or impossible to Him. Reasoning backwards, a process that every man should practice, there is nothing hard or impossible to man. In other words, if man is a replica of his Maker, and there is nothing hard or impossible to the Creator, then it is self-evident that there is nothing hard or impossible to man. This form of reasoning is taken for the time being to help inventors to appreciate the fact that they are not justified in neglecting to devise some form of mechanical wheel that will be quite satisfactory in automobile work; doing all that rubber is supposed to do, costing less to make and much less to maintain. It is far from a credit to the brains with which America is so liberally endowed that almost no progress is being made in this broad field, and, as the rubber men claim, the demand for that material, also of the better grades of cotton, is outstripping the supply, so that the needs of to-day are infinitesimal as compared with what they will be to-morrow, to say nothing about the influence of years upon this most important phase of industrial development.

When rubber strayed into the arts it brought with it a good example of the character of service that is wanted, but this material seems to labor under great difficulty in commercially imitating its own good example. If there is no possible chance of improvement on the length of service that rubber is capable of giving, then what is wanted is the service that rubber seems to render so efficaciously, the same to be delivered by some other material that will last longer under actual working conditions. The form of the new wheel may have to be quite different from all present forms; there may have to be many modifications of present practice, but all such matters are the merest details in the face of the main demand. Don't be discouraged; go to work.

Cantor Lectures on Motors

PROFESSOR W. WATSON, D.SC., F.R.S., DELIVERED THREE LECTURES ON THE GASOLINE MOTOR, OF WHICH THIS IS THE OPENING—BY PERMISSION OF THE ROYAL SOCIETY OF ARTS

IN these lectures I propose rather to deal with generalities and principles which are common to all petrol engines than to describe those details of construction which vary from one make of engine to another. I shall commence, however, by briefly describing in this first lecture some typical forms of engine, since a knowledge of the general construction will be required in order to follow some of the points with which I shall be dealing in the subsequent lectures.

Petrol engines, like all other internal-combustion engines, may be divided into two great classes, according as an explosion takes place in each cylinder once in every two revolutions of the crankshaft, or once in every revolution of the crankshaft. Engines belonging to the first of these classes are called four-cycle, or Otto-cycle engines, because the whole cycle of operations in each cylinder repeats itself after four strokes of the piston, two of these strokes taking place in one direction and two in the opposite direction, this corresponding to two complete revolutions of the crankshaft. Engines of the other class are called two-cycle engines, and here the complete cycle is repeated after two strokes of the piston.

Let us first consider the four-cycle engine. The sectional model which I exhibit represents what, up to within two years ago, appeared to be the type to which all engines of this class were settling down, and even now the vast majority of engines only differ from that shown in minor details. The peculiarity which distinguishes this type lies in the manner in which the admission of the explosive charge to the cylinder and the escape of the burnt products is governed, that is in the form of the valves. These valves, which are called poppet valves, are mushroom shaped, and they fit down on a conical seating formed by the cylinder wall. The valves are raised off their seats when required by means of cams on a shaft or shafts, which are connected, by gearing, to the crankshaft, and turn at half the speed of the crankshaft. In some engines the valves are in separate pockets, on opposite sides of the cylinder head, as shown in the model. In others the two valves are in the same pocket, while, finally, in some engines there are no valve pockets, but the valves are in the cylinder head.

Turning the crank of the model it will be observed that as the piston descends the inlet valve opens and allows a charge of petrol and air to be drawn into the cylinder. When the crank has slightly passed the lower dead center, the inlet valve closes, and then the rising piston compresses the charge. Just before the piston reaches the top of its stroke an electric spark is passed which ignites the charge. As we shall see, however, the mixture of air and petrol gets alight very slowly, so that before the pressure has appreciably increased, due to ignition, the piston will have reached the top of the stroke. While the piston is descending, the pressure developed by the burning of the charge does work, the downward pressure of the gases on the piston being converted into a turning movement on the crankshaft by the connecting rod and crank. A little before the piston reaches the bottom of its stroke, the exhaust valve is opened, and allows the hot gases to escape from the cylinder, the pressure in the cylinder rapidly falling from about 40 pounds per square inch to nearly atmospheric pressure. During the upstroke of the piston, the exhaust products remaining in the cylinder, are further expelled through the exhaust valve, which remains open throughout this stroke. The whole of the products of the explosion are not expelled, for the piston, when at the top of its stroke, leaves a space in the combustion head of the cylinder, which is about a fourth of the volume swept out by the piston. The cycle is now complete, and, as the piston descends, a fresh charge is drawn in and the whole process is repeated.

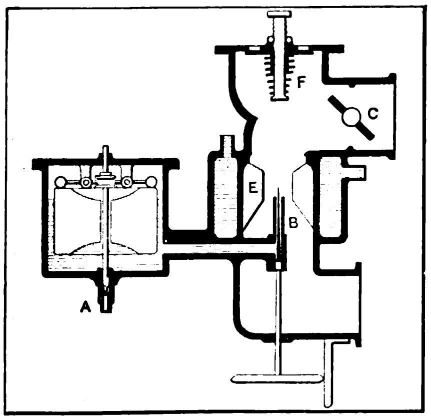

Fig. 1—Showing a simple form of jet carbureter

It seemed at one time as if the poppet valve would continue to be used exclusively, but the adoption, last year, of the Knight pattern of sleeve valve by the English Daimler Company, to the exclusion of the poppet valve, and the triumphant way in which two such engines came through a full-load test, lasting for 132 hours continuous run, conducted by the Royal Automobile Club, has not only silenced those who ridiculed the idea that there would be anything to compete with the poppet valve, but has started a number of designers and inventors testing other forms of valve. The section model exhibited, and the sectioned engine, which the Daimler Company have been good enough to lend me to show you this evening, will enable you to see how the Knight valve works. There are two sleeves inside the cylinder, the piston itself moving inside the inner sleeve. Ports are cut in the upper portions of the sleeves, those on one side for the inlet and those on the other for the exhaust. The sleeves are given a reciprocating motion by means of two eccentrics which are carried on a long shaft, which turns at half the speed of the crankshaft. As I rotate the crank (the piston starting at the top of its stroke), you will notice that the ports in the right of the sleeves register with the inlet port, thus allowing the charge to enter. By the time the piston has reached the bottom of the stroke, the ports in the sleeves no longer register, and, as the piston rises, communication is entirely cut off, so that the charge is compressed. When the piston has nearly reached the end of its path on the firing stroke, the ports on the left-hand sides of the sleeves register with the exhaust port, allowing the gases to escape, and this continues during the whole of the exhaust stroke. The peculiarity of this engine, to which I desire to call particular attention, is the large size of the inlet and exhaust ports. This can be clearly seen in the two separate sleeves which are exhibited. The size of the ports, and the uninterrupted path provided for the gases is a matter of very considerable importance.

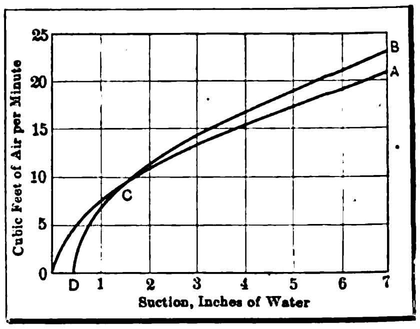

Fig. 2—Curve showing air taken in at different pressures

In the four-cylinder engines described above the cylinders and the crankcase to which they are attached are held fixed, while the crankshaft revolves, and with such a design it is necessary to provide a flywheel, even when four or six cylinders are used. In order to save the weight of the flywheel some designers of engines for aviation purposes have inverted the above-mentioned arrangement, the crankshaft being held stationary, while the cylinders and crankcase revolve, the propeller being either directly attached to the crankcase or driven by a sprocket carried by the crankcase. With this arrangement the cylinders themselves act as flywheel, so that the weight of a separate flywheel is avoided. Further, the movement of the cylinders through the air keeps them cool, so that no separate cooling arrangement, such as a waterjacket or fan, is required.

A diagrammatic section of the Gnome seven-cylinder rotary engine is shown, from which you will be able to form some idea of the general arrangements. Since, however, I have been unable to obtain drawings of the engine, the details shown must only be considered as more or less conjectural. It will be noticed that only one connecting rod has a bearing on the crankpin. The other connecting rods have bearings on this one connecting rod. The inlet valves are fitted to the top of the pistons, so that the charge enters the cylinders from the crankcase. The charge enters the crankcase through an axial hole down the stationary crankshaft. The exhaust valves are in the head of the combustion space, and are operated by levers and a camshaft, which turns at half the engine speed. It will be noticed that balance weights are provided to the valves. The object of these balance weights is to eliminate the effect of centrifugal force. The necessity for such balance weights will be obvious when I state that if the inlet valves weigh only 4 ounces, the centrifugal force at 1,200 revolutions per minute would amount to 160 pounds.

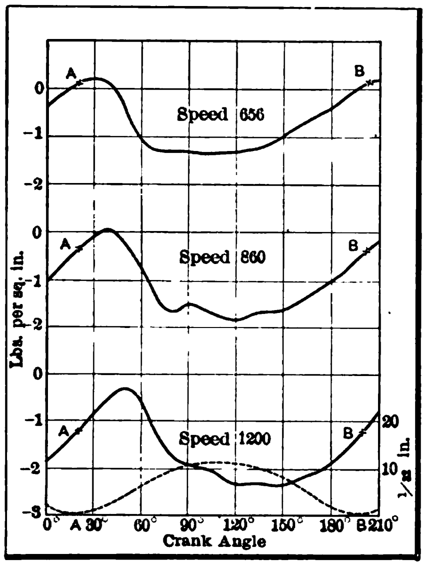

Fig. 3—Curve of pressure measured in the intake pipe of a four-cylinder engine

The great difficulty with the rotary type of engine seems to be that of securing adequate lubrication without an excessive consumption of oil. Thus, in a test of one Gnome engine, conducted by the French Automobile Club, the consumption of oil per horsepower-hour was 0.4 pounds, just half the consumption of petrol. An engine of the ordinary stationary cylinder type hardly ever requires more than about 0.05 pounds of lubricant per horsepower-hour, even when run continuously at full load.

The other diagram represents the two-cylinder, five-horsepower Granville rotary engine, which is of English design and manufacture. Here, as in the Gnome, the inlet valves are of the automatic type, *i. e.*, are opened by the fall of pressure in the cylinder on the induction stroke, and are situated in the piston head.

It is of interest to note that if the impulses due to the working strokes of the various cylinders are to be equally distributed throughout each rotation of the engine, it is necessary that there shall be an odd number of cylinders. This is at once evident if we remember that one complete cycle of each cylinder occupies two complete revolutions of the engine. Hence the firing of every alternate cylinder must follow, and. going round in this way, taking every cylinder, we must include all the cylinders while going twice round.

The two-cycle engines, in which there is a working stroke in each cylinder for each revolution of the crankshaft, act on a cycle which is the invention of Mr. Dugald Clerk. Although there are comparatively a small number of two-cycle petrol engines in use in England, in America there are a large number—chiefly in boats.

The principle on which most of these engines work is illustrated by means of the section model I now show. Let us suppose the piston to be at the top of the stroke, the combustion space containing a charge of inflammable mixture which has just been fired. The piston then descends on the working stroke and when near the end of the stroke it uncovers an exhaust port on the right-hand side of the model, allowing the exhaust gases to escape. During the descent of the piston the gases in the crankcase have been slightly compressed, and when, by its further descent, the piston uncovers a port connected with a short passage leading to the crankcase, these compressed gases flow through into the cylinder. The current of incoming gas is deflected upward by a baffle plate attached to the upper surface of the piston, and as they fill the cylinder they drive out most of the exhaust products through the exhaust port which is still open. As the piston rises it first covers the port leading to the crankcase and then the exhaust port. Further rise compresses the charge, which is ignited when the piston is nearly at the top of the stroke. During the rise of the piston a partial vacuum has been produced in the crankcase, and, when the piston is nearly at the top of its stroke, its lower edge uncovers a port connected to a carbureter, through which an explosive mixture rushes in to fill the crankcase. It is this explosive mixture which, after being compressed by the descending piston, passes into the cylinder through the inlet port when the piston reaches the lowest part of the stroke. It will be noticed that there are no valves in this engine, the piston itself performing the functions of both inlet and exhaust valve. The further consideration of this engine I will postpone till the next lecture, when I will exhibit some indicator diagrams, and discuss some of the advantages and disadvantages of this type. I may, however, draw attention to one of the chief difficulties in designing a satisfactory two-cycle engine. This is to prevent loss of the incoming charge through the exhaust port, and admixture of exhaust products with the fresh charge. In the case of the Lucas two-cycle engine, an attempt has been made to overcome this difficulty by dividing the cylinder into two parts; in each part there is a piston, the one piston uncovering the exhaust port and the other piston the inlet port. Since the combustion head is common to the two portions of the cylinder, the entering charge can blow right through, sweeping the exhaust products before it, and the liability to admixture between the fresh charge and the exhaust products, and the escape of the fresh charge through the exhaust port, is greatly diminished. Owing to the kindness of the Valveless Car Company I am able to exhibit a section model of the Lucas engine, from which the working of the engine will be clear.

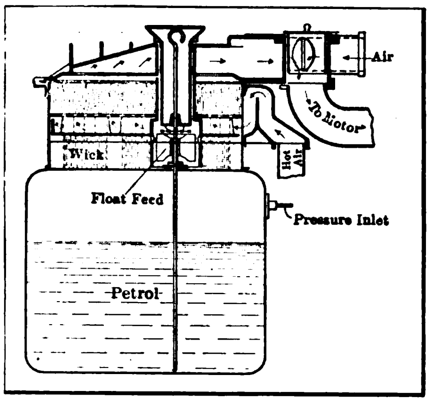

Fig. 4—Type of carbureter used on the Lanchester motor

Having briefly described the general construction of a petrol engine, it is necessary to consider, equally briefly, some of the auxiliary apparatus necessary before the engine can function. Chief among these is some arrangement for supplying an explosive mixture of air and petrol power, *i. e.*, a carbureter. Here, as before, I shall only take examples of the two types in common use in their most simple form. In the first class, which in practice is the most numerous, the petrol is supplied through a fine orifice or jet, and the air, as it passes to the cylinder, is sucked past this jet, and mingles with the petrol. A simple form of jet carbureter is shown diagrammatically, in section, in Fig. 1. The petrol reaches the carbureter by the pipe A and by means of a float and needle valve the level of the petrol in the jet B is kept normally a little below the top of the jet. The air enters at D, and at E passes a construction which surrounds the jet.

The air carrying the petrol, partly vaporized and partly as a fine spray, proceeds to the engine through the tube C. Owing to the reduction of pressure when the engine sucks air through C, and to the flow of the air past the jet, the petrol is projected in a stream through the jet, the amount of petrol flowing depending on the size of the hole and the amount of suction exerted. In the carbureter shown, the size of the orifice of the jet can be adjusted by advancing or retiring a needle which passes up through the center of the jet. With such a carbureter it is found that if the size of the jet is adjusted to give a correct mixture of air and petrol at low engine speeds, then at high engine speeds, when the velocity with which the air passes through the carbureter is much increased, the mixture becomes too rich in petrol. In this carbureter, however, as the suction increases, so that the difference in pressure between the induction pipe C and the external air increases, a valve F opens and admits air which has not passed the petrol jet, and this extra air mixes with the too rich mixture formed by the air which has entered at D, and so tends to keep the strength of the mixture supplied to the engine at the proper value. The necessity for the extra air at high engine speeds, *i. e.*, when the suction increases, is clearly shown by the curves given in Fig. 2. The curve O C A represents the number of cubic feet of air which will pass through a given carbureter for different values of the suction, that is of the pressure difference between the induction pipe and the external air. The curve D C B represents the amount of air which would have to pass in order that, when mixed with the petrol which was found to flow, it should give a correct mixture. It will be observed that till the suction amounted to nearly half an inch of water no petrol flowed. From this point up to a suction of about 1.7 inches the actual amount of air, as shown by the curve OC, is greater than the amount required to supply a correct mixture as shown by the curve D C, that is to say for engine speeds below that which will produce a suction of 1.7 inches of water, the mixture supplied is too weak. For higher engine speeds, on the other hand, it will be noticed that the mixture supplied is too rich. The meanings to be attached to the terms "too weak" and "too rich" will appear later when we are dealing with the combustion of air-petrol mixtures. The curves given in Fig. 2 were obtained when a constant suction was maintained, but when we come to attempt to apply these results to an engine, matters are further complicated by the fact that the suction exerted, even by a multi-cylinder engine, is by no means constant. This is clearly shown by the curves given in Fig. 3, which represent the pressures measured in the induction pipe of a four-cylinder engine at three speeds. The subject of the action of a jet carbureter is a most complex one, almost as complicated as are some carbureters on the market; and it will not be possible to consider it further in the time at my disposal.

The other type of carbureter is one in which the air, or at any rate part of it, as it passes into the induction pipe is drawn over a large surface of lamp wick, these wicks sucking up petrol from a reservoir. The best known carbureter of this type is that used on the Lanchester cars, and is shown in Fig. 4. Only part of the air passes over the wicks, this air being heated so as to assist the vaporization of the petrol. This air becomes heavily charged with petrol vapor, and is mixed with a certain proportion of cold air, which enters by the port marked "Air" on the figure. The advantage of this form of carbureter is that it is much simpler to regulate the constancy of the proportions of the hot petrol-charged air to the cold air, as we are dealing in each case with a gas, than to regulate the constancy of the proportion of liquid petrol flowing through a narrow orifice, to that of the air, which is a gas, for the laws of flow of gases and liquids are by no means the same.

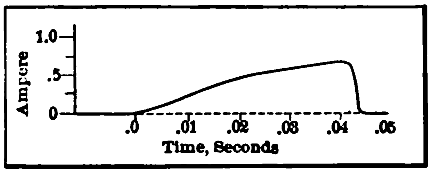

Fig. 5—Oscillograph curve of spark-coil performance

Since a considerable proportion of the petrol is vaporized in the carbureter and induction pipe, owing to the latent heat of the vapor, unless some method of heating is employed the temperature of the carbureter will soon fall below zero. That the vaporization of petrol will cause such a fall in temperature I can show by blowing air through some petrol contained in a flask. The temperature soon falls below zero, which fact is shown by the flask freezing a little water on which it stands, so that a block of wood adheres to the flask. The objection to the excessive cooling of the carbureter is that the vaporization of the petrol is retarded, so that an increased quantity of petrol is sucked into the cylinder in the liquid condition, and the presence of this liquid petrol probably increases the rate at which a crust of carbon forms in the combustion head. Further, if the temperature of the carbureter sinks below zero, the moisture, which is always contained in the air, becomes deposited as snow, and the carbureter becomes choked. The necessary heat can be supplied either by providing the carbureter with a jacket, through which some of the circulating water, or exhaust gas, is passed, or by heating the air before it enters the carbureter. This is generally secured by taking the air from the neighborhood of the exhaust pipe.

I shall proceed to show one or two experiments to illustrate the principles which are involved in firing the charge in the cylinder of a gasoline engine. When I pass an electric current through this coil, not only is the iron core magnetized, but also what is called a magnetic field is set up in the space surrounding the coil. The presence of such a field is indicated by the movement of a compass needle placed at some little distance from the coil. Now to move such a compass needle work must be done, and in the case before us this work has been done by the battery which has been employed to produce the current in the coil. Not only has the battery exerted a force on the compass needle, the effect of which is visible to us, but it has also produced a state of strain throughout the surrounding space, and has thus done work, although by our senses we are unable to perceive it. I can, however, make the energy which has been stored up in the medium in this way evident by suddenly breaking the circuit, so that a current no longer passes, when the energy stored up is returned to the coil, and, as a result, produces very considerable electrical effects. Thus, in this experiment the two ends of the coil are joined together through an electric lamp which to make it glow brightly would require a much higher voltage than exists while the current is passing. When, however, I break the circuit, so as to cut the battery out entirely, the energy in the field, which returns to the coil, is sufficiently great to cause the filament to flash out very brightly. That this effect is due to the energy stored in the field I can at once show, for the windings of the coil are double, and I can cause the current in the two halves either to circulate in the same direction or in opposite directions. In the experiment just shown they circulated in the same direction. I will now reverse the current in one of the windings. We now have the same current flowing as before and just as many turns of wire. There is no magnetic field, however, the iron core is not magnetized and the compass needle is not affected. On breaking the current the lamp does not glow.

The same effect can be shown by simply breaking the circuit in such a way that you can see the spark produced. With the current circulating in the same direction in both sets of windings a bright spark is produced. If, however, the direction of the current in one winding is reversed there is hardly any spark. This coil, and the spark which occurs when the circuit is broken, is an example of what is called the low-tension system of ignition. In this system there is a movable contact inside the engine cylinder, and by means of a cam or some such device, just before the piston reaches the top of the stroke on the compression, a circuit containing a battery and coil is first completed and then suddenly broken by the separation of the movable contact within the cylinder, the spark produced firing the charge.

The kind of time the current takes to reach its maximum value in an ordinary low-tension coil is shown in Fig. 5, which gives the curve obtained by Prof. F. W. Springer by means of an oscillograph. It will be seen that the current was still rising after 0.04 seconds.

In the Operation of a Car

THE STEERING WHEEL SWITCH; USING THE MOTOR IN STOPPING THE CAR; OTHER MEASURES FOR SAFE DRIVING. BY JAMES S. MADISON

ANYTHING which adds to the comfort or pleasure of the man or woman behind the wheel or anything which increases one's skill or tends to make the control of the car more perfect, is a boon for which we should be cordially grateful. Of all the accessories and additions which an owner may purchase for his car there are not many that are capable of giving him so much satisfaction as to have the control of the ignition under his thumb on the steering post or on one of the cross-pieces of the wheel. While many articles have been written directing attention to the obvious advantages of this simple device, it has been adopted by surprisingly few. Its merits and advantages are so pronounced that it is rather remarkable that its adoption has not become general. A recent count of automobiles passing a certain point on the Jersey Coast showed that out of 100 only 3 had the switch on the steering post or wheel.

With the present style switches of the lever, plug or knife variety, which are usually mounted on the dash, it is always necessary, in order to cut off the ignition at any moment, to lean forward, in what is often an uncomfortable position, and throw the switch with one hand, leaving the other free to steer the car if it is moving, or to remove one foot from the clutch or brake-pedal and throw the switch if it be of the lever or knife variety. If it be of the old-fashioned plug type, the hand must necessarily be used.

It is an excellent practice, as the initiated know, to use the engine for braking purposes on all possible occasions. The tendency to brake with the engine is a growing one. No driver should be satisfied with his progress until he has learned to use his engine as a brake regularly and consistently—this is one of the elements of skillful driving. With the control of the ignition on the steering post or wheel this becomes a simple matter, since the ignition is cut off or turned on with the thumb or a finger with the same ease that the spark or throttle lever is advanced or retarded. The definite advantages in having the mechanism controlling the ignition so conveniently placed that it requires no effort to manipulate it, are these:

1. In coasting down a hill, even a short one of not more than 50 yards, the ignition may be cut off, leaving the clutch engaged. This will cause the explosions to cease, but the fan and pump and all other moving parts actuated by the engine will continue in motion and perform their functions just as they do when the explosions are driving the pistons out and in. This gives the engine an excellent opportunity to cool off. When the ignition is cut off one should not fail to close the throttle, otherwise an explosive mixture will be drawn into the cylinders and transferred to the muffler, which may be easily damaged by the explosion which would follow on turning on the current. This is an economical procedure in so far as it saves gasoline, oil and current (unless one is running on a magneto). The disadvantage is that when the clutch is let in, near the bottom of the hill, there is a certain jar to the chassis and body, and a certain wear of the clutch which is avoided by leaving it engaged and cutting off the ignition.

2. In going along a crowded city street it is sometimes necessary to throw out the clutch and apply the brake many times before the car is clear of the congested traffic, or to reduce the speed by letting the clutch slip. The same object may frequently be accomplished more easily and economically by throwing the ignition off and on as often as may be necessary.

3. In descending a hill with a right-angle turn at the bottom, a condition frequently met in city or town streets, the turn may be easily and safely taken with the ignition off.

There are other advantages of the same kind that will readily suggest themselves to the careful driver.

To attach the device to the steering column proceed as follows: Select a suitable switch of any convenient size of the lever type, at any price the buyer wishes to pay from 25 cents up. This should be mounted on a block of wood about 2 1-2 x 3 x 5-16 inches, the back of which is hollowed out so that it will closely fit the steering post. The switch is fastened to the block by three small brass screws. The block is secured to the post by means of a piece of tin, sheet brass, or copper (which has been bent carefully to fit the post) fastened to the block by four small brass screws. The piece of metal is then painted black unless the steering column should be nickel-plated, in which case it would be desirable to use a piece of nickeled brass or aluminum. The binding posts of the switch are then connected to the magneto or battery, as the case may be, by a good quality of waterproofed insulated wire, of inconspicuous color, which is wrapped two or three times around the steering column. If one wishes to avoid the bother of making a switch for the wheel or post, he will find very excellent ones of neat design on the market costing from $3.50 to $5.

The only disadvantage the writer has found from using this device was owing to the fact that the bulb of the horn on his car is also fastened on the steering post, in order that it may be reached more easily than if it were at the side. It is necessary at times to leave the car stand for an hour or more in exposed places. On two occasions the passing small boys in surreptitiously honking the horn, inadvertently or otherwise threw on the switch, with disastrous results to the battery. In order to eliminate this trouble, a common "Ideal" knife-blade switch, costing 25 cents, was screwed on the battery box; one of the lead wires was cut and the two ends connected to the binding posts of the switch. When it is necessary now to leave the car stand unprotected for any length of time, the knife blade switch is left open.

If a car provided with such a switch should be caught without the top in a rainstorm, it would be necessary to protect the exposed parts of the switch from the rain in order to prevent faulty ignition.

Took Permission to Publish for Granted

There are two sides to every question, and, while the giving of credit may convey a flattery, it might even be construed to the contrary. But when the plagiarist exhibits absent-mindedness, it is the sincerest of flattery, for then it is plain, on the face of it, that he wishes to retain the credit for himself.

THE ROYAL AUTOMOBILE CLUB JOURNAL

1910 Edison Storage Battery

SECOND INSTALLMENT—DEALING WITH WALTER E. HOLLAND'S PAPER AS PRESENTED BEFORE THE TWENTY-SIXTH ANNUAL MEETING OF THE ASSOCIATION OF EDISON ILLUMINATING COMPANIES, HELD AT FRONTENAC, THOUSAND ISLANDS, N. Y., SEPTEMBER 6, 7 AND 8, 1910

INNUMERABLE repetitions of tests have shown that the cells as commercially manufactured have surprisingly uniform capacity and that under any similar conditions, no matter how abnormal, different cells will give practically identical results. The same characteristic of constancy of behavior applies also to the different sizes of cell, and at comparative rates they have similar characteristics, except for inconsequential variations in heating due to differences of radiating surface. This is shown in the curves of Fig. 4.

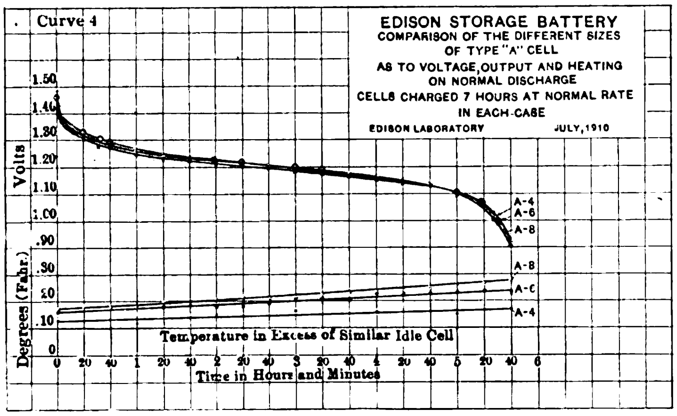

Fig. 4—Showing effect of temperature upon the capacity of the different sizes of battery

In work with the Edison battery the necessity of some reliable and convenient method of analyzing voltage curves, to determine which electrode was limiting the capacity or causing changes of voltage, was early appreciated. The only scheme which had then been tried was the use of the metal container of the cell as a third electrode in the same manner that cadmium is used in lead cell tests. This was a most convenient scheme, but the readings so taken were inconstant and not at all reliable on account of polarization which would be set up at the surface of the nickel-plated steel, even by the infinitesimal current taken by a high-resistance voltmeter.

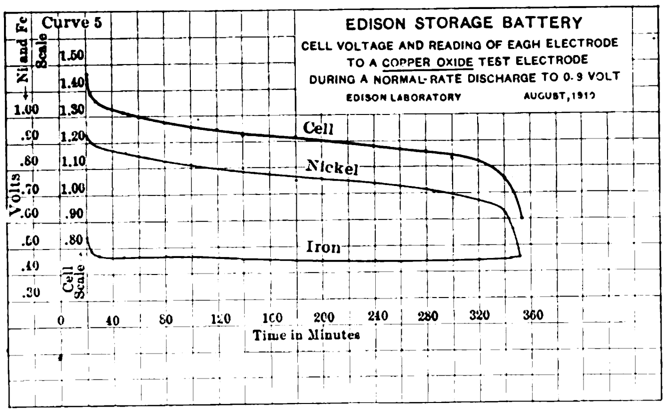

Fig. 5—Cell voltage of the respective electrodes using a copper oxide electrode for testing purposes

The author has devised several successful schemes to the end in view. One of these is theoretically applicable to any kind of primary or secondary battery, and practically also where suitable means exist.

The first device tried was that of a duplicate charged cell standing idle alongside the cell under test and having electrolytic connection with it through an inverted U-tube. Voltage readings would be taken from the positive of the cell under test to the negative of the auxiliary cell, and from the negative of the working cell to the positive of the auxiliary cell. The voltage of an idle charged cell remains practically constant over long periods of time, so variations in the readings thus taken must be caused entirely by the working electrodes, and the resultant curves would show the independent behavior of these. This method proved reliable, but was inconvenient; and in the case of batteries in actual service could hardly be employed at all. The best scheme devised—one which has been used many years at the Edison laboratory and has been successfully applied to various kinds of battery, including the lead storage battery—may be described in general terms as follows: The use as a third electrode of a partially reduced oxide which will undergo electrolytic oxidation or reduction in the given electrolyte without polarization. That the oxide should also be insoluble in the electrolyte is of course highly desirable, as its use cannot then contaminate the cell in any way. The oxide must be mounted in a suitable conductive support, and the electrode is preferably encased in perforated hard rubber so that it may be rested on the plate tops with impunity. For the common electrolytes substances fulfilling the above requirements are numerous, but those which the author has found best adapted to use are: lead peroxide for sulphuric acid batteries, and either cupric oxide or the high nickel oxide of a charged Edison positive for all alkaline batteries.

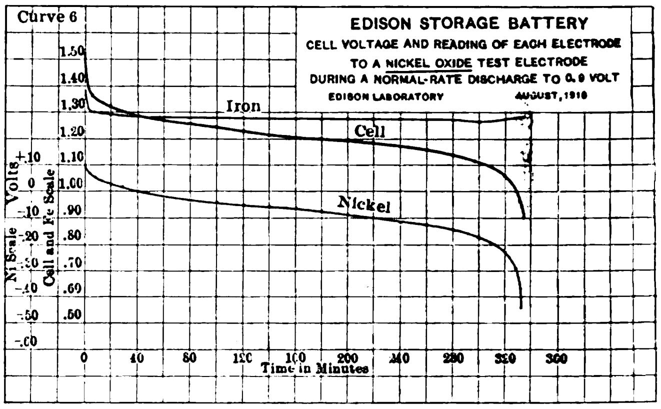

Fig. 6—Cell voltage of the respective electrodes using a nickel oxide electrode for testing purposes

A copper-oxide test electrode can be prepared very easily from a plate of agglomerated cupric oxide such as is sold for use in the Lalande primary battery. A small block cut from a new plate of this kind is bound with fine copper wire and suitably insulated. It is then made cathode, using a passive anode, in a jar of the alkaline electrolyte—a medium current being passed for an hour or so, or until about one-fifth of the block has been reduced to metallic copper. After this treatment the electrode should be allowed to stand in electrolyte for a few days fo "season"—that is, to become stable in voltage. The electrode is then ready for use and will remain in working condition almost indefinitely, provided it be kept in dilute electrolyte when not in use. If exposed to the air for very long the reduced layer of metallic copper will reoxidize. Cupric oxide is very slightly soluble in strong alkaline solutions; but in the case of the Edison battery it has been found to have no deleterious effect, even when present in large amount, and can be used with perfect safety.

Test electrodes of nickel peroxide and lead peroxide are best made from portions of positive plate of the respective batteries in which they are used. Connection should be made to each by metal of the same kind as that used for support of the active material, and perforated rubber insulation should be provided. These electrodes are prepared for use by fully charging and partially discharging them. They should also be seasoned by standing in electrolyte, as in the case of copper oxide.

Test electrodes of nickel peroxide and of lead peroxide have been found to give excellent results in tests of the Edison and the lead battery, respectively, and have the advantage of being indigenous to those batteries so that no foreign substance is introduced. Peroxide of lead also has the advantage over cadmium of not requiring so much care to keep in condition; its properties do not seem to be affected, even by a drying out in the air.

Fig. 5 shows a normal rate discharge of an Edison cell with independent curves of the electrodes taken by means of a copper-oxide test electrode, and Fig. 6 shows the same taken with a nickel-oxide test electrode. Fig. 7 shows typical nickel-oxide readings for a normal charge.

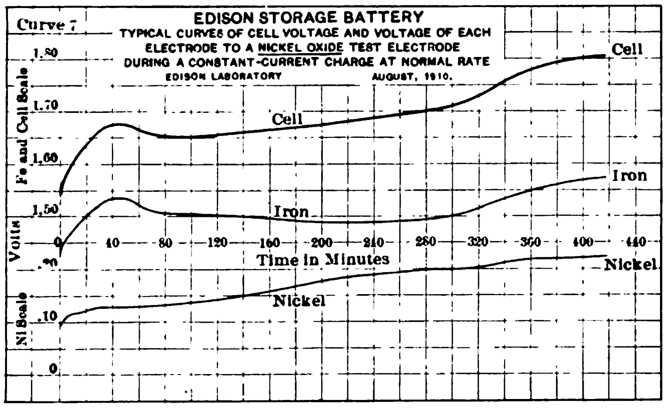

Fig. 7—Typical curve of cell voltage using a nickel-oxide electrode for testing purposes

The fixing of the normal charge and discharge rates and normal length of charge of the Edison battery is mostly arbitrary. The "normal" current rates given were determined by a careful consideration of the factors of I^2R loss in cell and the resultant heating, of time rates of charge and discharge, and of output; and were presumed to strike the best balance between the governing factors to suit the conditions of vehicle practice. Seven hours is taken as the normal length of a charge at normal rate simply because at this point the output and efficiency were judged to be in the best relation for average practice. These ratings are not obligatory, but the length of charge may be varied between zero and infinity as desired, and should be varied according to the output required in any particular service. The rates of charge and discharge are optional also when just two points are kept in mind. The first is that very low charge rates will not completely reduce—that is, charge—the iron element, and the resultant discharge will be anomalous as to voltage (see Fig. 8). No permanent injury has ever been known to come from low-rate charging, and the discharge will usually recover normal characteristics when the cell is again worked regularly at normal rate. If not, then overcharging at normal rate and discharging to complete exhaustion will certainly re-establish normal conditions. Secondly, it should be kept in mind that although excessive heating does no immediately apparent harm to the battery, continuous working at high temperature will have an injurious effect tending to shorten its life.

What the true ohmic resistance of a storage cell is need not be known; the virtual internal resistance, that is, the factor which is effective in causing internal dissipation of energy, is the value of practical importance. The prescribed method of finding this is to momentarily open the switch at intervals during a discharge and read the electromotive force; then the difference between the value thus found and the potential difference while current is passing would represent the I R drop in the cell due to its effective resistance, and this value divided by the current rate would give the virtual internal resistance at the given point of discharge. This method is hard to apply because when the switch is opened the interruption of current changes the electromotive force to such an extent that the voltmeter needle continues to rise for some time afterward, and the true value of the electromotive force is very difficult to determine.

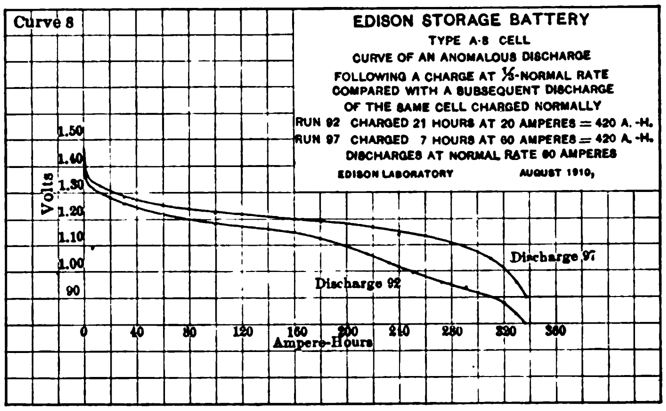

Fig. 8—Curve of an anomalous discharge after a charge at 1-3 normal rate, making comparisons

A better scheme is to simply reduce the current to a lower value instead of interrupting it entirely, and dividing the difference between the voltages at the two rates by the change of current. Obviously the same result can be achieved through momentary increases of current; and to get the most reliable test the methods should be combined and the current worked both ways on the same discharge. Thus, taking the concrete case of an "A6" cell discharging at 45 amperes, the current should be changed to 15 amperes and 75 amperes alternately for, say, half-minute periods every twenty or thirty minutes. Then the difference between the voltage at 45 amperes and that at either the low or high rate, divided by 30 amperes would give the true virtual internal resistance for the particular conditions. Fig. 9 is a curve of internal resistance obtained by this method; it shows the average values for an Edison cell discharging at normal rate under ordinary conditions.

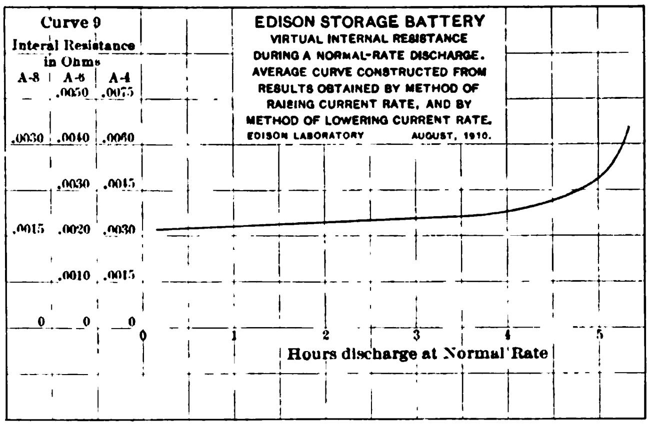

Fig. 9—Showing virtual internal resistance determinations during a normal rate discharge

DISCUSSING MATTERS OF INTEREST TO USERS OF AUTOMOBILES; LOCATING ENGINE KNOCKS; TO PREVENT INJURY TO THE LEGS IN ACCIDENTS IN SCUTTLE-DASH CARS; PEINING PISTON RINGS; A REMEDY FOR WORN BRAKE BLOCKS, ETC.

Locating an Engine Knock

Editor The Automobile:

[2,405]—I wonder if you can aid me in identifying and correcting a knock in my engine. The knock is regular, occurring in one cylinder. It cannot be in the ignition, as it is distinctly noticeable after cutting off the ignition when stopping the car; nor in the compression, which tests all right in all cylinders. It is more noticeable when the throttle is well open than when it is nearly closed.

There is also a pronounced "hissing" sound in one cylinder when the car is running and the engine is at all labored. This may have something to do with the knock, but it is doubtful. It is less noticeable when the throttle is closed down than when wider open with the engine running slow.

Mesilla Park, N. M. Francis E. Lester.

This knock may be due to a number of different causes, and we are inclined to think that the noise is in the cam shaft. On some of the earlier models of this make of motor the retaining screw in front camshaft bearings wore slightly and if there is any end play in camshaft it would knock against the screw, causing a very distinct and regular knocking noise. This can be overcome by discarding the use of this screw and substituting an automatic thrust take up fitted to the front end of the camshaft. This consists of a little bronze boss with ball bearing and spring adjustment. If this is fitted, however, the knock may be due to a ring slap, which can be overcome by slightly slotting the tops of the rings.

In looking for trouble of this sort in a motor it is half the battle to make up your mind that you are going to locate it. If you feel whipped from the start it is a moral certainty that the knock will have the best of you from the start to the finish.

Scuttle Dashes and Accidents

Editor The Automobile:

[2,406]—In the event of an accident to a car that is fitted with a scuttle dash, what possibility is there of the passenger and driver seated in the front clearing the metal covering without injury to their legs? One often hears of accidents where the passengers are thrown clear and coming off with only slight bruises.

G. T. Melson.

York, Pa.

The scuttle dash is being used for two reasons—one to improve the lines of the car and the second with the addition of front doors to keep the wind from the lower parts of the body. It would be useful to have a leather pad fitted in the manner shown in the accompanying sketch (Fig. 5); this would soften the impact in case of collision.

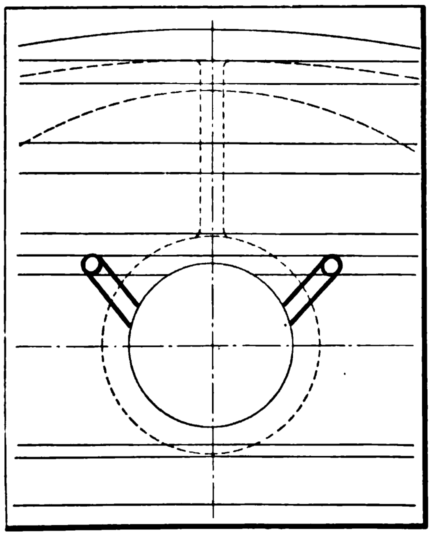

Fig. 1—Method of overcoming insufficient lubrication of wrist pin

A Trio of Pertinent Inquiries

Editor The Automobile:

[2,407]—Being a subscriber of your magazine, I would like to ask some questions:

1. Why does a motor lose power as it is speeded up above 1,800 revolutions per minute?
2. What do you think of a worm-gear drive for a magneto as used on Rutenber motors, the worm being on timer shaft?
3. Which do you think is better, valves on one side or opposite sides? Give reasons. Fred Wells.

New York.

1. Motor does not necessarily lose power over 1,800 revolutions per minute, as there are several motors that give maximum power at speeds well over 2,000 revolutions, and some over 2,500 revolutions per minute. The maximum speed of an engine is governed by the setting of the valves and the size of the valve seat and outlet ports; as an example, one of the small cars with a 4-inch bore had three exhaust valves to its one cylinder. On engine speed curves of some motors the falling off of power indicated by the falling line is due to the fact that the speed is too great to allow the charges to be either properly gotten to the cylinders, weakness of mixture, or back pressure of the exhaust. It is supposed that the ignition is correct, although, while it is possible to obtain instruments to fire at, say, 3,000 revolutions per minute, some do not give satisfactory results above a certain speed, and this can only be determined by trying out several different makes.

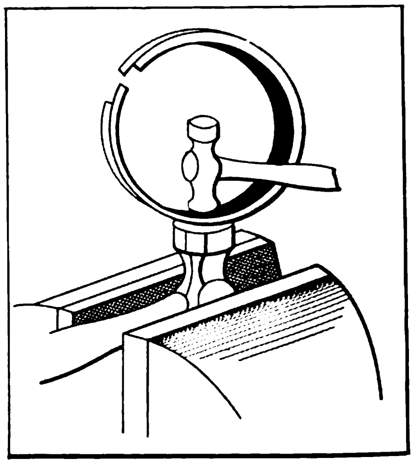

Fig. 2—Showing method of peining piston rings

2. The worm gear for magneto drive is equally as good as the straight-tooth type, with the advantage that it is quieter, and the backlash occasioned by the armature leaving the magneto suddenly could be better taken care of with a worm.

3. As to which is the best is a matter that depends upon how the motor is made; or, better still, how well it is made. The type you do not mention, viz., the overhead type, obviates all pocketing, which is bound to occur to some degree, no matter how small in the "L" or the "T" type of motor.

Another Tip on Piston Rings

Editor The Automobile:

[2,408]—With reference to your recent replies on piston rings and the method of peining same, I have heard it said that they should be struck from the inside. As I should like to try this method, could you tell me how it is done? Tyro

Wilmington, Del.

The accompanying sketch (Fig. 2) will show you the method employed, as in the case where a blow is struck externally care must be exercised in hitting a fair blow.

To Remedy Worn Brake Blocks

Editor The Automobile:

[2,409]—I am troubled with the brakes on my car, as after adjusting them to the full extent they will not hold the car on an incline. The car is of foreign manufacture, and the agents say it will take some time to obtain the part from the factory if I wish to order new shoes. How can I use the old shoes?

Georgetown, D. C. **Mark Baldwin.**

First of all, you do not say if the shoes are of an internal expansion or external contraction type of brake. The latter can be fitted with new liners made from cast iron, copper or hard brass, but the former can be remedied by filing the places where the opening block touches and fitting two new pieces of steel, as shown in Fig. 4, so that when the wheel is put on again and the brake rods are set at the smallest amount of adjustment possible the brake will start to operate, and your trouble will be ended.

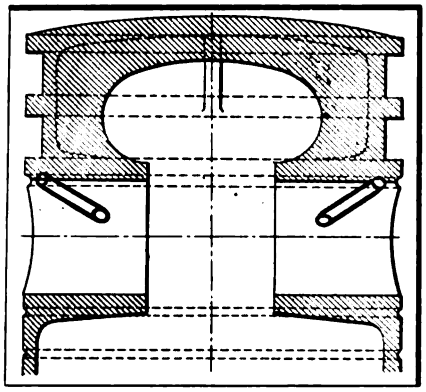

Fig. 3—Showing holes drilled through flanges of piston

Removing Carbon from Cylinders

Editor The Automobile:

[2,410]—Will you please inform me as to the best method of removing carbon from cylinders by the use of kerosene? I have had trouble with the carbon fouling the valves when blowing it out after using kerosene. Will you kindly tell me how much to use in each cylinder and the best way to get rid of the kerosene after using? I have put cocks only in the tops of the cylinders.

Also, do you recommend pouring kerosene in the air intake of the carbureter for the purpose of removing carbon instead of pouring the kerosene in the tops of the cylinders? Also, should a small quantity of lubricating oil be put in the pet cocks in the tops of the cylinders after using the kerosene?

I am a subscriber to your paper, and your courtesy in answering these questions will be much appreciated.

Newark, N. J. **H. J. Bradley.**

To remove carbon by injection of kerosene in the cylinders is at the best a makeshift method of removing this objectionable foreign matter. A method that has given satisfaction is as follows, if the valves are not placed in the head of the cylinder:

Turn the engine so that the pistons are on a dead level, and pour through the pet cocks or valve plugs sufficient kerosene to cover the pistons about one and a half inches and allow it to remain all night. A good quantity by the morning will have found its way past the rings into the base chamber. Now take out the exhaust valves and exhaust manifold and turn the engine several times to allow any remaining kerosene to be expelled; turn the engine so that the piston is in position. If you have no such implement, make or purchase a carbon-removing tool, and through the exhaust valve plug or outlet port, if it is placed conveniently, rake out the carbon, which will be soft. The next operation is most important, and it is upon the care with which this is done that the success of the whole operation lies. It will be understood that the inlet valve has not been touched. Take the inlet valve plug out, and what it was impossible to reach from the exhaust side should be pushed toward the latter. Wash out with kerosene from the inlet plug to the exhaust by means of a syringe, and finally with a mixture of kerosene and gasoline, half and half, clean out with some fresh rag, but always see that the inlet valve of the cylinder that is being worked upon is closed. It is advisable when the pet cock is placed in the head of the cylinder to remove same and pass a wire down it, as the orifice often becomes clogged with carbon, and although the piston and cylinder are clean the carbon in the cock becomes incandescent and causes preignition. It is preferable to pour the kerosene into the cylinder direct rather than to take it in by way of the induction pipe.

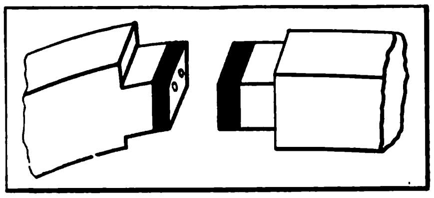

Fig. 4—Worn brake blocks repaired

As regards the lubricating oil, the base chamber should be emptied and fresh oil inserted before running the engine, and, as you suggest, insert a small quantity of lubricating oil in the cylinder as well. This can be done through the valve covers, first allowing the piston to go below half-way down, and by this means pour the oil on the walls instead of on the piston head.

Inserting a small quantity of kerosene through the pet cocks after every 300 miles should help to keep the engine clean. Some piston heads are turned rough, and will pick up carbon quickly. If this is so in your case much trouble can be avoided by taking them out and having them polished smooth.

Lubrication for Wrist Pins

Editor The Automobile:

[2,411]—I have a four-cylinder car that has recently developed a knock, and the other day I took the engine down and found that the wrist pins had worn perceptibly, and showed signs of scoring, as if they had not sufficient oil. Lubrication is by pump to maintain a constant level, and the walls of the cylinders and the wrist pins are dependent upon splash. Is there any method you can suggest to lubricate the new wrist pins to prevent them going like the original set? J. W. L.

Philadelphia, Pa.

If the hole in the top of the connecting rod is not large enough the following method ought to cure your trouble: As Figs. 1 and 3 indicate, drill the pistons through the inside flanges or webs and turn a small slot to catch the oil, and on the upward stroke it will find its way to the wrist pin.

There should be oil slots cut in the bush in the connecting rod, otherwise oil cannot find its way in to lubricate the pin. The pins should be turned a few 1,000ths larger than required. case hardened and afterwards ground to the required size.

Questions That Arise

CONCERNING PUMPS FOR MAINTAINING PRESSURE IN THE GASOLINE TANK; SPANNER FOR INACCESSIBLE NUTS; TO START A CAR IN COLD WEATHER; CLEANING ACETYLENE GAS BURNERS

[254]—What is the specific gravity, weight per cubic inch and weight of aluminum compared with cast iron and copper?

Specific gravity pure aluminum in cast state is 2.58; weight per cubic foot, 0.092 pounds; weight compared with wrought iron, 1:2.90; as to copper, 1:3.60.

[255]—What style of pressure pump is there in use which does not require a relief valve for keeping pressure in the gasoline tank?

The accompanying sketch (Fig. 1) shows a section of a hollow plunger pump operated by a cam from the half-time shaft. When the plunger is forced upwards air contained in the upper enclosed chamber is compressed until the highest point is reached, when a small port is uncovered, forcing the gases past a ball valve acting as a non-return. The contained air, which, owing to the capacity of clearance space, cannot exceed a pressure of 4 pounds, does away with the necessity of the safety valve.

[256]—What is the condenser on an induction coil?

A number of sheets of tinfoil laid together with thin oiled or varnished paper or other non-electric substance between them. The ends of alternate sheets of the foil are connected together and two groups of interlying sheets are thus formed. These become charged with electricity when the current is interrupted and when the circuit is closed again the electrical energy stored is quickly given out.

[257]—Can a spanner for inaccessible nuts be made?

A method employed by some mechanics (?) is to take a chisel and hammer and strike a few blows on the nut side to loosen it when it is stiff. This method cannot be too strongly condemned. If a nut is inaccessible and has to be taken off from time to time it is better to make a spanner to fit it and with one such as shown in Fig. 2 the hammer and punch can be used *ad lib.*, as it is the correct way to use this spanner.

[258]—When should the inlet and exhaust valves begin to open and when should they close?

This is a matter that has been differently handled by different makers, and a great amount of variation is found in the opinions of eminent designers of gasoline motors. Taking the inlet valve first, in some cases this is made to open when the piston is on the dead center, others with a seven per cent. advance, and again with as much as 14 degrees retard, or the valve does not open till the piston has traveled 14 degrees down on the suction stroke.

The time of closing cannot be altered on any particular car once the opening has been set, as this is controlled by the profile of the cam. In two different motors where the inlet valves open 13 and 14 degrees late respectively the closing of the former takes place 10 degrees after the piston has started on the upward compression stroke, while the latter does not close till the piston has arrived at 35 degrees of its upward stroke, allowing that 180 degrees is the equivalent of one whole stroke, and not one revolution.

With regard to the exhaust valve this is usually made to close almost immediately the piston starts on the suction stroke, but slightly over the dead center, and it is on the closing of this valve that the timing must be set and not on the opening, which may vary from 10 to 50 degrees on the explosion stroke. From the foregoing it will be seen that the inlet valve must be timed by its opening and the exhaust on its closing.

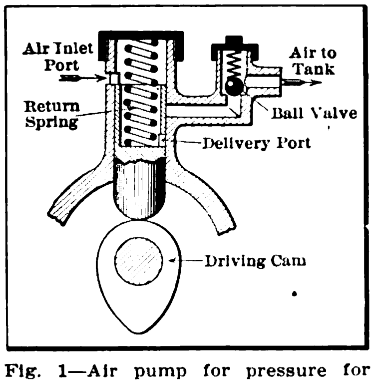

Fig. 1—Air pump for pressure for gasoline tank

In some motors the inlet valve opens before the exhaust has fully closed and in case of doubt or if the timing wheels are not marked, communication with the makers will be the easiest way out of the difficulty.

[259]—What is the best way to start a car that has been laid up for some time, or refuses to start owing to cold weather?

Do not fly to the usual remedy of pouring gasoline into the cylinders by the compression cocks or spark plug holes if it is stiff. The cause of the stiffness is probably due to the dryness of the cylinder walls, as the lubricating oil has either dried up or found its way back to the base chamber. Mix an equal quantity of kerosene and lubricating oil together and inject same into the cylinder and with the spark off turn the engine several times to allow the mixture to percolate past the rings and so lubricate the walls. Injection of gasoline will aggravate the trouble of dryness and render the compression weaker than it already is, and it is due to the poor suction on the carbureter that a mixture strong enough cannot be gotten to the cylinders to ignite and start the motor. If, after the lubrication treatment has been applied the motor refuses to start, then a small quantity of gasoline can be used. In Winter the cold may have the effect of partly solidifying the lubricating oil and in this case also kerosene is a better remedy than gasoline to liquefy it.

Holding a heated rag over the carbureter and induction pipe may be resorted to if a coating of ice forms on the outside of the pipe. Once the engine has been started it is better to allow it to run for a few minutes before starting to run the car.

[260]—Is there any means of cleaning lamp burners for acetylene headlights that have become clogged?

Soak the burners in nitric acid and afterwards hold them in the flame of a Bunsen burner. Clearance may be effected by a piercer of exact size, but this is difficult to obtain and the matter from which burners are made being very brittle, extreme care should be exercised.

French Makers Alarmed at Importations

Alarmed at the success attained by the importers of foreign cars, and the numerous victories of foreign cars in speed and hill-climbing contests, the French manufacturers have voted in favor of some big demonstration for the year 1911. The nature of the demonstration has not been decided upon, but it is understood that the French manufacturers have in mind a big road race or an important touring competition. The race is more likely to be adopted than the touring competition, for European manufacturers are of the opinion that definite racing restrictions, whether they be limited bore, limited fuel, or a weight restriction, have more influence on the breed of automobiles than the most trying touring competition that can be devised. The movement in favor of the "demonstration" has taken the form of a recommendation from the Chambre Syndicaee de l'Automobile that the Automobile Club of France should take this matter in hand for the 1911 season.

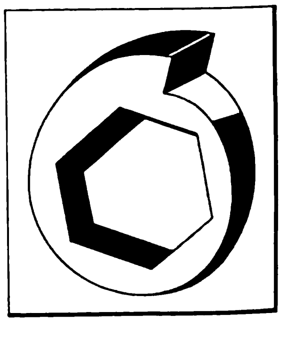

Fig. 2—Spanner for inaccessible nuts

Digest

EXTRACTS FROM CONTINENTAL JOURNALS ON SUBJECTS ALLIED TO AUTOMOBILE ENGINEERING: CAST IRON STRENGTH AND SPECIFICATIONS—THE SABATHE KEROSENE MOTOR —THE RISE IN BENZOL

Specifications for cast-iron parts have only of relatively recent date been subjected to regulations of recognized value and this has been one of the reasons for discrediting castings as parts in automobile construction, their strength being difficult to determine in advance. The reason why practice and science have refrained from formulating basic rules for deciding the strength and properties of cast-iron parts, even though foundry science has progressed by leaps and bounds, is to be sought in the fact that the unit strength of a casting, even in the case of comparison between materials derived from the same ladle, depends largely upon the dimensions of the piece and the more or less rapid cooling to which it has been subjected. The same difference arises with regard to a single cast piece, according to the direction and location of the stress. The strength along one cross-section varies from the strength through another section, and the difference is not pro rata with the dimensions. Slow cooling, as where the diameter is greatest, produces a coarser structure and also causes carbon to be precipitated as graphite between the walls of adjacent crystals, greatly reducing strength. Flexion tests made by O. Leyde with bars of square section of different dimensions and all cast in one piece with a heavier bar uniting them across one end, showed that the softest iron developed the most pronounced differences in unit strength, in favor of the bars of small section. A bar 10 by 10 millimeters in section endured a stress of 47 kilograms per square millimeter, while a bar of 150 by 150 millimeters cross-section endured only 18 kilograms per square millimeter. In three series of tests the materials differed mainly in silicon, this metalloid running from 2.1 per cent. in the hardest to 1.5 per cent. and 1.2 per cent. in the softer grades. The composition otherwise was carbon 3, phosphorus 0.6, manganese 0.7 and sulphur 0.12. Similar results were reached in tests by Sulzer Winterthur Brothers with bars from 5 to 50 millimeters in diameter, giving a strength decreasing from 63 kilograms for a bar of 5 millimeters diameter to 27 kilograms for the largest size. The Society of German Iron Foundries has now created regulations for cast-iron tests in which the principal source of error in previous rules—the use of only a single dimension of bar—is eliminated. The new regulations distinguish between: A, machine castings of (1) medium, (2) high and (3) very high strength; B, architectural and construction castings, and C, pipe castings, comprising (1) gas and water pipe and (2) steam pipe. Each subdivision is further divided according to dimensions of the casting in three classes: (1) Pieces with walls up to 15 millimeters thick, (2) between 15 and 25 millimeters and (3) average wall thickness of more than 25 millimeters. Further regulations extend to shapes, properties of the material and method of producing test bars. In addition to flexion tests here is provided test by internal hydraulic pressure for tubular castings. The testing work which was called into action by these regulations at the various foundries has created a demand for a special machine for facilitating the measurements, and one such has been produced by the Düsseldorfer Machine Company, Inc., and is provided with automatic stress-measuring instrument and recording manometer giving direct reading in kilograms.—*Metall Technik,* August 6 and 13.

The construction of the Sabathe kerosene motor, mainly intended for boats, which was described in this column last week, is shown in Fig. 1. *A* is the admission pipe, *E* the exhaust pipe, *C* the camshaft from which are operated the valves and the kerosene injection pump *G*. *D* represents four rings made of anti-friction metal and placed below the piston rings to insure rigidity and tightness and avoid danger of fire from gas leaks. One similar ring is placed above the piston rings. Note the mounting of the cylinder in the jacket, by which it becomes possible to turn the cylinder around its axis and avoid ovalization.

Each ton of coked coal yields 3 to 5 kilograms of rectified benzol. The annual French production of 32 million tons of coal offers a sufficient supply of automobile fuel. At present France consumes 50,000 tons of benzol annually. The new industry of producing it was begun in 1896. First the mines in the North, especially those at Lens and Anzin, which are engaged in the production of coke for the steel furnaces, installed new apparatus for recovering the by-products, viz., coal tar, ammonia, benzine, benzol, toluene and heavy oils. France was far behind Germany in this respect. The consumption of benzol was then only a few hundred tons per year, in France, and the price was high, reaching 100 to 200 francs for 100 kilograms. The principal employment of the substance was for dyeing and similar small chemical industries. After the first installation of benzol-producing apparatus there was a sharp decline in the price, due to overproduction. But in three or four years the demand more than caught up, and in 1901 new installations were made. The mines at Aniche, Escarpelle, Bethune, Dourges, Douchy and the Société Lorraine de Carbonisation began to produce benzol. Prices at once dropped again. There was a lull in production. Suddenly the gas engineers took up the idea of using benzol, which has a very high illuminating value, for the enrichment of illuminating gas, and it also began to be employed as fuel for stationary motors, and prices again rose to 40 and 50 francs per 100 kilograms. Finally the automobile movement gained strength. England turned to the production of benzol and makes now 35,000 tons per year. Belgium produces 6,000 tons, and Germany 70,000 tons. At the present moment France produces 13,000 tons and uses 50,000 tons of benzol, a large part of which comes from Germany. The anomaly has arisen, says M. F. Laur in *Journal du Pétrole,* that German benzol competes duty-free in France against American, Roumanian and Galician gasoline on which an import duty of 12.50 francs per 100 kilograms is collected, thus reducing the State revenues about 5 million francs, while at the same time free-trade England has imposed a tax of 3 francs per 100 kilograms on motor fuels, with especial view to the exclusion of German benzol. Rectified and washed 90 per cent. benzol sells now for 13 to 19 francs per 100 kilograms, f. o. b. Paris (city excise not included), while gasoline costs 30 to 33 francs. A rise in its price seems imminent.—*La France Automobile,* September 3.

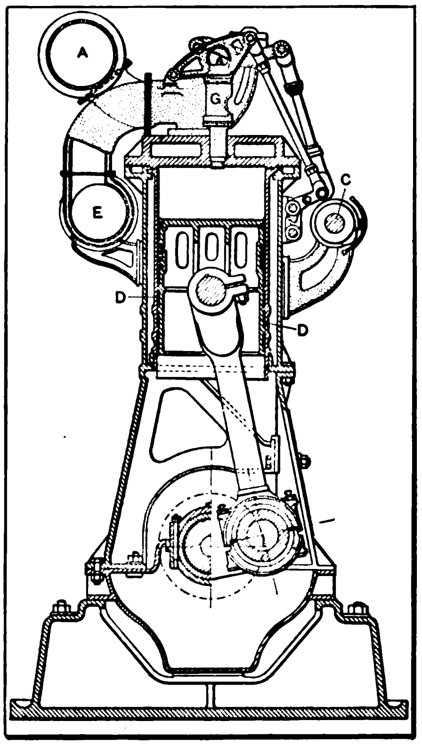

Fig. 1—The Sabathe kerosene motor

Injunctions

Don't fiddle on one string; the noise is dreadful; the string is sure to break.

Don't tell about what you are going to do—go do it.

Don't pray to the Lord for a chicken dinner and take that as a license for you to rob a hen roost.

Don't jolly yourself into the idea that robbing a hen roost differs much from overcharging an autoist who entrusts you with the repair of his automobile.

Don't obligate yourself with promises to deliver more automobile than the kind that you are selling represents; the purchaser might hold you to it.

Don't pray to the Good Lord to come and relieve you of your earthly burden and then say that you are out when the Lord knocks on the door.

Don't burden yourself with a load that you would like to palm off on the Lord—if you will only play fair with the automobiling public the sunshine of prosperity will gladden your soul.

Don't grow corns on your tongue telling every person whom you can buttonhole how you scalped a farmer's chicken—you would squeal like a stuck pig were you to drop a sou in a crap game.

Don't listen to a knocking demonstrator: while he is riveting your attention to the failings of a competing make of car he is leading you away from the good qualities of the automobile that he is trying to fasten upon you.

Don't loan money to the character of man who would hold you so lacking in acumen as to listen to him while he tells you how bad the other make of car is—he is a biased advocate, and he is so hungry that he would charge you interest on any money that you might be foolish enough to loan him.

Don't saunter around Automobile Row making believe that you are about to invest in an automobile, only that you are having difficulty in finding one that is good enough for you—just go home; bewilder your wife by displaying a little sense; besides, she may be in need of the car-fares that you are squandering in a futile attempt to disguise a pouter pigeon—it can't be done.

Don't start out to buy a car by telling the maker all about how you think it ought to be made; it would require as much time in relating what you do not know about automobiles as it would to describe the clothing that a South Sea islander does not sport.

Don't approach a prospective with the solemnity of an undertaker; he may not feel sure that there is a vacancy in Heaven; be cheerful.

Don't murder a prospective's resolve to join the ranks of autoists; if the automobile you have to offer does not check up with his requirement, direct him to the place where he can get it—you know.

Don't fail to lubricate the springs; this is a simple thing to do; pry open the leaves with a screwdriver and squirt a little lubricating oil in between them.

Don't put up with a strange noise; if it is noticed get out a search warrant and serve it upon the pest; it will grow and prosper if you disregard it.

Don't imagine that a noise is too insignificant to pay attention to; it means that there is something the matter; have it fixed.

Don't assume that membership in a club, even if it is a large one, gives you any right that is not enjoyed by other autoists when it comes to driving an automobile on the highway; the mantle of the law is supposed to cover all with equal protection.

Don't forget that membership in a club multiplies the loudness of the voice for good by the number of the members if all pull together—pull in unison, that is the wise course to pursue.

Non-Freezing Solutions

GRANTING that there is very little trouble from freezing water in automobiles when the motors are in more or less constant use or stored in a garage that is kept fairly heated, the fact remains that the cylinder jacket water will freeze up if automobiles are in an unheated garage, or if they are stood out in the cold all day without running the motors to maintain a state of warmth sufficient to prevent the water in the circulating system from reaching the freezing point, which is 32 degrees Fahrenheit. Experienced autoists understand this situation quite well, but those who are newcomers may not realize that the very efficiency with which radiators serve their intended purpose constitutes a source of danger, due to the ease with which heat is transferred from the water to the surrounding atmosphere.

What is true of the water that is circulated to maintain the cylinders at a working temperature is equally to be said for the water that circulates through the carbureter for heating purposes, it being the case that the water first goes to the cylinders, where it is heated, and some of it then passes into the carbureter jacket, where its heat is abstracted from it by the gasoline which, being something of a refrigerant, tends to lower the temperature and the heat from the water overcomes this difficulty. But when the motor is shut down and there is no means of maintaining the heat in the water, it is then under the influence of the surrounding temperature and, on account of the efficiency of the radiator and other parts for the transfer of heat, it is but a matter of a short time when the water will be so reduced in temperature that it will freeze.

There are a number of ways of preventing water from freezing, as when some foreign substance is placed in solution. Of the several materials that are used for this purpose some of them are not recommended, due to the fact that they will either foul up or attack the metals with which they will contact as the water holding these elements in solution is circulated in contact with these metals. Common salt is used in refrigerating work on account of its ability to take up a large amount of energy in the form of heat at low temperatures without freezing. In this class of work, in view of the corroding action of the salt, nothing but iron is used throughout, but in radiators and the piping system of automobiles there is more than iron, and salt is therefore debarred from use.

Calcium chloride is available to some extent; it must be chemically pure, however, and this is a difficulty that is not easily overcome owing to the danger of not being able to procure chemically pure calcium chloride with absolute certainty. For those who care to experiment with this material for non-freezing mixtures, the table as here given for its properties will afford the requisite data from which to make a solution that will suffice for the coldest Winter work in the latitude of New York.

One of the safest solutions to employ is made up of water and glycerine. The proportions of glycerine to water for the various temperatures may be determined by consulting the table as here afforded, for which THE AUTOMOBILE is indebted to Messrs. McKesson & Robbins, New York City.

There still remain the various solutions of alcohol and water, using either wood alcohol or the denatured product, which is sold under the trade name of "Pyro-Alcohol." In any event, using alcohol, it is necessary to test the cooling solution at frequent intervals in order to determine its strength and to replenish the alcohol as often as may be necessary to maintain the strength of the solution, compensating, of course, for the part of the alcohol that evaporates off. Just how often it will be necessary to re-establish the strength of the alcoholic solution depends upon the

.CIUM CHLORIDE MIXTURES; GLYCERINE IS REC- IENDED; WOOD ALCOHOL MAY BE USED; DE- TURED ALCOHOL IS POPULAR

efficiency of the cooling system and the amount of boiling off that takes place in regular service.

SOLUTIONS OF WOOD ALCOHOL AND WATER FOR MOTORS

Percentage of wood alcohol	Freezes at Degrees Fahrenheit	Specific gravity
5	25	.994
10	17	.988
15	10	.982
20	5	.975
25	—3	.969
30	—10	.963

Note.—The specific gravity of alcohol or other solutions may be determined by means of a suitable hydrometer. For alcohol there are special instruments of this character to be had.

SOLUTIONS OF GLYCERINE AND WATER FOR MOTORS

Per cent. glycerine	Freezes at	
	Deg. Cent.	Deg. Fahr.
10	—1	30
20	—2.5	27
30	—6	21
40	—17.5	0
50	—31	—25

Note.—Up to 30 per cent. glycerine can be used without material effect on the rubber hose connections, but if a stronger proportion is used the connections will have to be renewed frequently. No matter how little glycerine is added to the water the mixture will after some time become muddy and must be thrown away and a new solution made to replace the old.

CALCIUM CHLORIDE SOLUTIONS FOR MOTORS

Percentage of calcium chloride	Freezes at Degrees Fahrenheit	Specific gravity
5	27	1.04
10	22	1.08
15	15	1.13
20	about 0	1.18
25	—10	1.22

Note.—The best way to make the solution is to make a saturate solution of the chloride and then use this, by adding water to it till the required mixture is reached. This is done by taking half a gallon to 8 pounds of chloride for each gallon of saturate solution desired. You can tell if it makes a saturate solution by the fact that some of the crystals will remain in the bottom undissolved. It is advisable to add to this solution a handful of lime to render it alkaline. This latter is done, as it is said that this solution has an acidic action on the metals of the whole cooling system, setting up an electrolytic action.

SOLUTIONS OF DENATURED ALCOHOL AND WATER FOR MOTORS

Percentage of alcohol	Freezes at Degrees Fahrenheit
10	25
20	12
30	—3
40	—20
50	—35

[The figures given are from the United States Industrial Alcohol Company.]

The volume of the mixture of alcohol and water does not remain the same as their combined addition. This is due to the fact that gases that are held in the liquids separately are less soluble when the two are brought together and the contraction described is the result of the disengagement of such gases.

5 per cent. alcohol in water 0.31 contraction
10 " " " " 0.72 "
15 " " " " 1.20 "
20 " " " " 1.72 "
25 " " " " 2.24 "
30 " " " " 2.72 "
40 " " " " 3.44 "

Automobile Trade Directory Just Out

The Automobile Trade Directory for the current quarter has just been issued and in some respects the work is more complete than ever before. It contains 808 pages, of which considerably more than half are devoted to classified text covering every branch of the trade, the remainder being occupied by a selected list of advertisements. In addition to the ordinary indices the directory contains thirteen pages of cross references touching 2,125 subjects.

Instructions

Should the magneto fail to properly perform its functions the fault may be due to:

(a) Lack of protection.
(b) Second-thought installation.
(c) Poor wiring.
(d) Inferior spark plugs.
(e) Improper timing.
(f) Lost motion in control system.
(g) Weak magnets.
(h) Defective insulation.
(i) Loose electrical connections.
(j) Open circuit.
(k) Excess of lubricating oil.
(l) Bad alignment.
(m) Defective bearings.
(n) Worn out brushes.
(o) Pitted collector rings.
(p) Poor ground connections.
(q) Static discharge.
(r) Induction interference.
(s) Defective design.
(t) Mechanical interferences.
(u) Unequal polar gaps.
(v) Magnetic leakage.
(w) Loose driving gear.
(x) Loose spindles.
(y) Loose magnets.
(z) Faulty switch.

Remedies for Magneto Troubles

(a) Fit leather or vulcanite cover.

(b) Take down and reinstall properly.

(c) Poor wiring always spells trouble; fit new.

(d) Inferior plugs are worse than bad wire; the best for magneto is not too good.

(e) Retime; if you are not sure ask some one who is.

(f) Take up slack, and keep connection oiled to obviate wear.

(g) Have them remagnetized.

(h) This is sometimes difficult to locate; after you are sure it does not lay in the wiring or bedplate, send the magneto to the makers if the mechanic handy does not thoroughly understand magnetos.

(i) These should be looked to often, and where possible fit lock nuts.

(j) Go over switch to find fault.

(k) If it has not got in the armature clean all parts and use less oil often and little rather than a lot now and then.

(l) Causes wear quickly if sideways; make holes for holding bolts larger; if too low pack up with thin fiber.

(m) Have them rebushed.

(n) Fit new ones.

(o) Clean with gasoline, or if badly worn use very fine emery paper.

(p) Undo same, wash with gasoline and clean with emery paper; if the spot is likely to be covered with oil make new connection elsewhere.

(q) Close safety gap slightly.

(r) Caused by flaw or improper windings; have same repaired.

(s) Outside owner's power.

(t) Readjust the parts so that they clear.

(u) Take out all plugs and adjust them all to one gauge of between 1-32 and 1-64 inch.

(v) Avoid a magnetic short-circuit by keeping the magnets clear of iron brackets, etc.

(w) If key is worn, have new key cut and keyways cleaned; if pinned to shaft, ream holes and fit larger pins.

(x) Have shaft turned true and rebushed to accommodate same.

(y) Tighten up holding screws.

(z) Repair same, but if cracked it is better to fit a new one.

Electric Vulcanizers

DISCUSSING THE NECESSITIES OF TIRES; STATING HOW REPAIRING MUST BE DONE; ILLUSTRATING AN ELECTRIC VULCANIZER, AND THE TOOLS THAT ARE NECESSARY

RAW RUBBER, while it is sticky and has certain cementing properties, is lacking in permanence in this regard. The adhesive properties of the rubber may be compared to molasses under temperature changing conditions. When the weather is cold the molasses will stick like flypaper, but as the temperature is raised the sticking properties of the molasses fall away until at a high Summer heat it will run like water. Raw rubber has properties that are not possessed by molasses and it is on this account that it is found to be of value in tire making; rubber is waterproof; molasses is not; in fact, it dissolves in water. Now, while molasses is thinned by heat, rubber is hardened; here is another distinct difference. The rubber may be so altered in its chemical composition, or better yet, characteristics, that, when it is diluted with sulphur or other suitable substances, it will not only harden under high temperatures, but it will thereafter remain so. If it is desired to keep the rubber from hardening too much, all that has to be done is to use less of the sulphur, or other vulcanizing substances, and regulate the vulcanizing heat to that which is known to produce the desired result.

Now, rubber is used in tire making for the purpose of sticking the layers of fabric, one to the other and all together. It is also employed to seal up the cotton, of which the fabric is composed, in order that mildew and other rotting agents may be locked out. In addition to the performance of these functions, the rubber is employed in a compound to make a toughened tread for the tire, so that when it rolls over the rough ground, contacting with sharp stones and other impediments, the fabric will be protected, it being the case that the toughened tread of rubber compound is better for this purpose than any other material that is now sanctioned for use, excepting, of course, that there are special forms of treads that do good work, and they are frequently used in conjunction with rubber for the accomplishment of this end, notably leather treads.

At all events, the rubber does several things, none of which is of the character that popular belief seems to accord to it. True, rubber is a resilient material, and that a rubber ball will bounce is too well known to be denied. The fact remains that it is the air in the pneumatic tire that is given the privilege of doing the bouncing part, and it is understood by those who have studied the matter, that air, under pressure, is far better than rubber for all such purposes, as cushioning the blow.

Leaving it to air, then, to do the work of dampening the blow and serving as springs for the automobile, it remains to emphasize the part that rubber plays in tires, and right here it will be well to mention the fact that this strange material, in addition to being waterproof, is airtight; inner tubes will hold air under pressure because the walls are of such fine texture that air, even under pressure, leaks through very slowly indeed.

If it is understood just what part rubber plays in tires it will be possible to discuss the care of them, with the hope that the needs of the occasion will be appreciated. The strength of the tire resides in the cotton fabric; this strength will prevail as long as the fabric is protected from its enemies, they being mildew, rust, acid, grease, dirt, and mechanical efforts, as flexure, centrifugal strains, excessive loading, and abrasion or cutting.

Disregarding the mechanical strains for the time being, since they are secondary to the present point of view, it remains to discuss the points that rubber is mostly concerned with. It will be seen that anything that will keep mildew away from the fabric will also bar out everything else that will not serve as a solvent for the rubber compound. Unfortunately, some of the substances that come into contact with the rubber will dissolve it; among these solvents grease is the material that is most likely to be encountered, although it is well known that dishonest chauffeurs, when they want to collect commission on new tires, put gasoline in the casings, and this liquid soon eats away the rubber compound, exposing the fabric, which the gasoline helps to rot out in a short space of time.

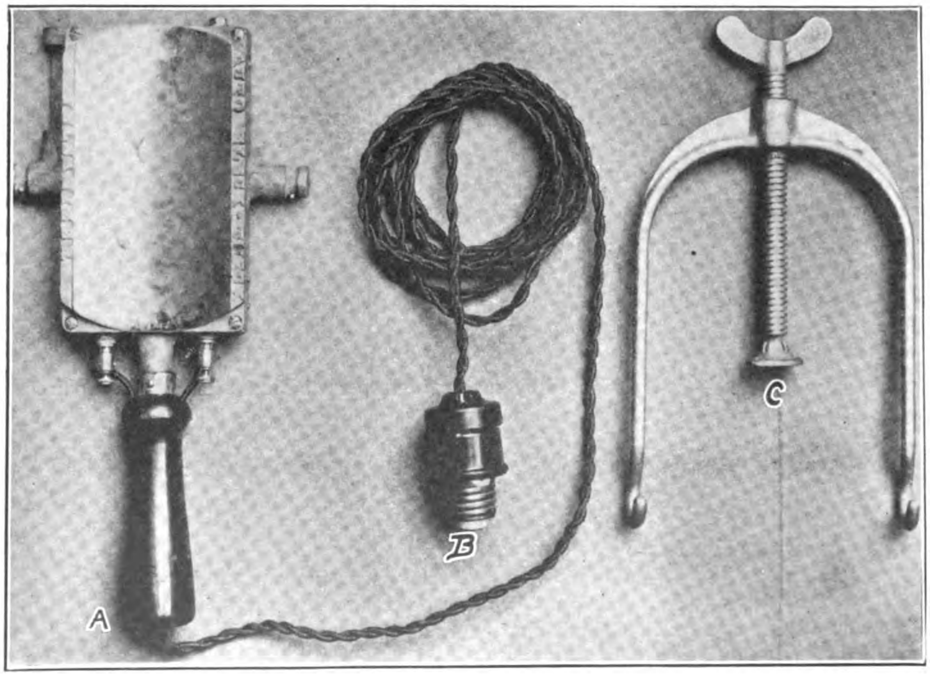

Fig. 1—A, vulcanizer; B, plug to screw into electric light socket; C, clamp for holding the vulcanizer to the tire

But the rubber, as long as it is kept in perfect condition, does ward off all honest natural enemies, as mildew, dirt, etc., and if the rubber can be kept in perfect condition, the tires will last for a long time. But this is the difficulty; automobilists, while they kick like the dickens at the tire bill, fail to appreciate the needs of the occasion, and, instead of healing up the little blemishes on the surfaces of the outer casings before they begin to fester, they wait until the cotton fabric, which, as a wick, pulls in a vast amount of water, and with it a horde of mildew, is all eaten away, sometimes for a foot or more away from the surface blemish that is responsible for the damage.

Just how large an opening will have to be to allow the cotton fabric to "wick in" water and mildew, that is ever in solution, is a matter which autoists differ about, but it is a moral certainty that the water and the mildew are content with a very minute opportunity. With such an active, though natural enemy, it is no wonder that there are so many dissatisfied automobilists, and there are as many of them as there are careless men who use automobiles and let them go to the dogs.

Since tires are very expensive, and none too lasting under the best of conditions, why is it such a large undertaking to do the small amount of work that will make them wear perhaps three times as long, as they will when they are neglected.

In the repair of little wounds—remembering that they are more dangerous than big cuts because they may be left unattended to for a month or more, whereas big cuts will compel immediate attention—assuming that the tire is cleaned with tepid water and castile soap to begin with, it remains to swab out the wounds and open them up a little, if necessary, preparatory to the application of the desired amount of the proper grade of cement to be used for this purpose.

The best cement to employ is not to be arrived at by just going to the nearest bicycle store and buying a tube of rubber cement. Each make of tires on the market has some proportion of rubber compound that differs from the other, and the right cement to use is that which will stick to the particular compound of which the rubber of the tires is composed.

Having procured the proper grade of cement for this purpose and having applied it to the cleaned and enlarged wound, it still remains to vulcanize the patch, if such it might be called, ere the new rubber will adhere and remain permanently attached to the old.

There are various types of vulcanizing appliances to be had; some of them are large and cumbersome, depending upon the heat from steam, under pressure, to afford the desired warmth; this class of vulcanizers is used in the plants where tires are made; room and bulkiness are not important factors there, but in the owner's garage it is scarcely to be supposed that a steam vulcanizer would lend facility to the plan. Electric vulcanizers, under the circumstances, are looked upon with much favor, and, since they afford the desired amount of heat at the right temperature, if they are properly designed, all that remains is to procure and use them with the assurance that the tire bill will be very materially reduced, provided, of course, that the work is promptly done.

The principle of the electric vulcanizer is that of the electric heater or rheostat. It is made up of a shell of metal as shown in Fig. 1, holding a set of electric conductors, they being relatively high in resistance. When the electrical energy is connected to the vulcanizer through wires leading from a proper source, as an electric light wire of the right voltage, by attaching the two wires to the binding posts of the vulcanizer, the electric current that will flow through the resistance wires, as they are called, will deliver up its energy in the form of heat, and the amount of heat generated will be sufficient to raise the temperature of the vulcanizer to about the point of vulcanization of the rubber compound. A means is available for regulating the flow of electric current, and a thermometer is also provided for the purpose of reading the temperature at any time during the process of vulcanization. It is desirable to avoid having the temperature crawl up too high, and the repairman should watch out for this. The thermometer should be a "corrected" one, that is to say, it should be one that has been tested to make sure that it will read off the true temperature within very narrow limits.

Fig. 2—A, folding case; B, brush; C, pliers; D, hook; E, skiver; F, marker; G, shears; H, roughener

For this class of work there are certain tools that will be of excellent service, and the wisest way to purchase an outfit is to include the tools. Fig. 2 shows just such a set of tools, and the vulcanizer with tools complete may be had with a sufficiency of detailed instructions to enable an automobilist of no great skill to do a good job the first time. The illustrations are of the vulcanizer made by James L. Gibney & Bro., New York City and Philadelphia, Pa.

Coming Events

CALENDAR OF FUTURE HAPPENINGS IN THE AUTOMOBILE WORLD THAT WILL HELP THE READER KEEP HIS DATES STRAIGHT—SHOWS, RACES, HILL-CLIMBS, ETC.

Nov. 19-26.......Oakland, Cal., Idora Park Show, Under Management of Oakland Automobile Dealers' Association.
Dec. 1...........Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Dec. 31-Jan. 7, '11.New York City, Grand Central Palace, Eleventh Annual International Automobile Show.
Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Manufacturers.
Jan. 15-21, 1911..Detroit, Wayne Gardens, Detroit Automobile Dealers' Association.
Jan. 16-21, 1911..New York City, Madison Spuare Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Jan. 28-Feb. 4,'11.Chicago Coliseum, Tenth Annual National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Pleasure Cars and Accessories, Exclusively.
Feb. 6-Feb. 11,'11.Chicago Coliseum, Tenth National Automobile Show Under the Auspices of the National Association of Automobile Manufacturers, Inc., Commercial Vehicles, Pleasure Cars, Motorcycles and Accessories.
Mch. 4-11, 1911...Boston, Mechanics' Building, Ninth Annual Show, Licensed Automobile Dealers' Association.

Races, Hill-Climbs, Etc.

Oct. 22-30........Belmont Park, New York, International Aviation Tournament and Show of Licensed Automobile Dealers of New York City.
Oct. 27-29........Dallas, Tex., Track Meet.
Oct. 28-29........New York City, New York "American's" Motor Truck Contest.
Nov. 3-5..........Atlanta, Ga., Speedway Meet, Atlanta A. A.
Nov. 5-6..........New Orleans, La., Track Meet.
Nov. 5-7..........Los Angeles-Phœnix Road Race, Maricopa Automobile Club.
Nov. 7-11.........Five-day Reliability Run of Chicago Motor Club, 200 Miles a Day.
Nov. 10-12-13.....San Antonio, Tex., Track Meet.
Nov. 11-12........Savannah, Ga., Road Race, Savannah Automobile Club, and Grand Prix, Automobile Club of America.
Nov. 24...........Santa Monica Road Race, Los Angeles, Cal.
Nov. 26-27........Los Angeles, Cal., Track Meet, Motordrome.
Dec. 25-26........Los Angeles, Cal., 24-Hour Race, Motordrome.

Entered at New York, N. Y., as second-class matter.
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907.

NOW that the first cost of automobiles is reduced to a stable and satisfactory level, concomitant with an increasing quality that eliminates speculation bearing upon the cost of maintenance from the purely mechanical point of view, it remains to discuss the phases of maintenance cost, such as will ultimately better the situation, thereby bringing the automobile well within the reach of the man who has no hesitancy in paying the first cost, but who might be dragged down by an undue expense account following the operation of the car. A casual inspection of the customary items of maintenance will show that fuel and lubricating oil are within reason, although it is to be expected that something can be done to trim these items down, partly by harmonizing the relations of the power plant to the chassis, and to quite an extent, when users learn to be moderate, paying some attention to the road conditions, adjusting the speed accordingly.

* * *

THE preponderance of maintenance cost is chargeable to the tires. Automobilists have in this item a serious problem to cope with, and the struggle they are experiencing could scarcely be more effective were they bent upon making the tire bill as large as possible. In the leading article this week in THE AUTOMOBILE the problems of maintenance are taken up broadly, with the expectation that the whole subject will be treated, taking, perhaps, several weeks. It is there pointed out, among other things, that by actual count the automobiles which are driven by chauffeurs are subjected to tire abuse by the wholesale, and it does seem strange that owners of automobiles will pay a fat lazy lubber real money for no better purpose than to permit him to collect commissions on the tires which will have to be purchased to replace those that are not given a chance to wear out.

* * *

BUT even the owners who drive their own automobiles stand in their own light, since they fail to grasp the significance of rubber in the structure of pneumatic tires; the popular belief is that this substance is put into tires for the same reason that it is employed in rubber balls, *i. e.*, to make them bounce. This belief is a good even mile distant from the true situation; rubber is used in tires for the same reason that paint is put upon a house. The class of people who labor under the impression that houses are painted to make them look well belong in the same category as the man who accepts the rubber ball theory. Paint is made up of linseed oil and pigment. The pigment gives body to the oil, preventing it from streaking. It is not out of place to employ artistic colors, since they do not prevent the pigment from doing its work, but the linseed oil, having a close texture and elastic properties, coats over the wood, or rather material, sealing it up tightly, so that oxidation and the ravages of hungry fungus growths will not induce a condition of rapid deterioration. Linseed oil would scarcely serve as a coating for the fabric used in pneumatic tires, but rubber is used instead.

* * *

IN recounting the theory of the pneumatic tire, air is used as the resilient medium, the inner tube being made of rubber compound, the latter being impervious to the seepage of air under pressure, but the rubber itself, being incapable of resisting any great pressure, has to be backed up by something of greater strength. Cotton fabric is employed in the casing because of the resisting qualities of cotton, when it is new; but owing to the rapidity with which mildew and like fungi attack and destroy cotton, just as fungus attacks and destroys wood, a protecting coat of rubber is applied to the layers of cotton, and as long as this coat remains intact mildew is debarred; but if the cotton is exposed at any point its "wick-like" properties are at once brought into play; water is drawn in, and with it come myriads of mildew and like fungi. It remains for automobilists to repair wounds in the rubber coating of tires before mildew sets up its festering influence.

* * *

CONSIDERING the high first cost of pneumatic tires and the rapidity with which they wear out, even when they are well cared for, there is reason enough for encouraging automobilists to avoid the maluse of their cars, and to instruct their chauffeurs to ride in a trolley car, excepting when they are helping the owners to realize value for service. If tires are now being made as well as it is possible to do so, using the best grade of rubber, superior staple, and the utmost skill in the process, it certainly does remain for the automobilist to put his foot down upon all tire abuses, learn what the rubber is for, and take advantage of whatever little value there is in it.

15% Cut in Tires

MANUFACTURERS WILL SLASH PRICES HORIZONTALLY DECEMBER 1, THUS RELIEVING MOTORDOM OF A DAMPER ON THE TRADE CAUSED BY CORNER IN RUBBER MARKET

RUBBER tires, the most puzzling element of motoring, are to be sharply cut in price on December 1. A horizontal slash of 15 per cent. has been decreed and the new order of things will go into effect on that date.

The course of the raw rubber market has followed the inexorable laws of supply and demand and at present is in the neighborhood of $1.40 a pound. When The Automobile last Spring published the facts about the manipulated condition of the rubber market abroad, the price of Para rubber in the open market was over $3 a pound.

It was pointed out that the tire men hesitated to buy under those conditions as the prices paid for raw rubber would have made the price of tires prohibitory and would have exerted a deadening effect upon the automobile trade generally. Then came a conference of the A. L. A. M. at which a decision was reached not to force the tire men to buy in the manipulated market by insisting on entering contracts for their tire supplies.

The article in The Automobile was widely read and was cabled in its entirety to London and the news it contained caused the raw rubber market to waver and then fall about a dollar a pound when the holders of large blocks of rubber realized that they would have to take profits speedily or not at all.

Since then the course of the market has been downward, with a few little strong spurts when isolated manufacturers tried to secure their annual supply. The tire men say that the current level is still too high and no purchases of great importance will be made until they can be executed somewhere about $1.20 a pound.

Even under the improved conditions that have obtained so far this Fall the cost of tires has proved a big obstacle to motoring and the general reduction will be particularly gratifying to the automobile public.

The understanding of the tire men and the makers is still in force and the manufacture of tires has been conducted conservatively. Outside supplies of raw rubber have been called upon rather more extensively than ever before and in the exact measure that the demand has been released from the central rubber market, prices have sagged off.

Tire men are somewhat apprehensive lest the announcement of the cut will have the effect of stiffening the demand for the finished product and have taken precautions not to stimulate the raw rubber market by heavy purchases.

They say that the market is in a nervous condition and shows signs of a "corner" whenever a big buying order is shown.

1911 A. L. A. M.'s Last Show

AUTOMOBILE EXHIBITS IN NEW YORK WILL BE CONDUCTED IN FUTURE BY THE LICENSED DEALERS' ASSOCIATION, BEGINNING WITH 1912

WHEN the doors of Madison Square Garden close upon the automobile show to be conducted by the A. L. A. M. next January, they will have closed upon the last show ever to be held by that organization in New York. In 1912 the display of automobiles in the metropolis will be handled by the licensed dealers' association and the show will be in the same class as that held annually in Boston.

Naturally, such a show will have considerably more weight and volume than the New England show, but it will not be a manufacturers' exhibition. The reasons for this action are two fold. In the first place the holding of a manufacturers' show is an appreciable element of expense that can be taken care of in another way. In the second place, the real reason is that the dealers in motor cars object to a manufacturers' show in their territory. This objection rises not so much from the fact that the makers sell some cars in the dealers' territory as from the tangles that have arisen in the past and are feared in the future in spoiling sales for the dealers.

The situation eliminating the national manufacturers' show will leave the Chicago show as the only simon-pure makers exhibition in the United States.

While plans so far in the future are still rather nebulous, the announcement as above will be received with much favor by the trade.

Johnson Company to Show at Palace

Space to exhibit its line of automobiles, in the Palace show, has been contracted for by the Johnson Service Co., of Milwaukee, Wis., according to statements coming from the company itself. Herbert Longendyke, one of the promoters of the show, entertained the press at luncheon at the Automobile Club of America last Thursday and explained the scope of the show enterprise.

Mr. Longendyke announced that he would establish headquarters at the Palace within a short time and would conduct a vigorous campaign. So far, his visits to New York have been periodical. He has not yet authorized the publication of his list of exhibitors.

San Francisco Auto Show Planned

San Francisco, Oct. 3—Plans are now being laid for an automobile show to be held in this city during December or January. Behind the movement is the San Francisco Motor Club. The Coliseum, in which two of the previous shows were held, has been rebuilt, and it is probable that the exhibition will be held in this spacious structure.

The automobile dealers of Oakland are also getting ready for a show. Their exhibition will be held in November, according to the present plans. Most of the large number of cars that are represented in San Francisco also have their agents or sub-agents in Oakland. It is understood that harmony now reigns and that there will be a complete representation in the show.

Little Space Left at the Boston Dealers' Show

Manager Chester I. Campbell of the Boston show has allotted the space to the accessory men, the latter taking nearly all that was left after the Boston dealers had been supplied. There is still a little here and there held as a sort of reserve and from these places some of the applicants among the dealers who were unable to get anything when the allotment was made to agencies and branches will be supplied.

Reeves Addresses Students

GENERAL MANAGER A. L. A. M. TELLS Y. M. C. A. CLASS ABOUT THE OPPORTUNITIES AFFORDED BY THE AUTOMOBILE INDUSTRY TO LIVE MEN

ALFRED REEVES, general manager of the A. L. A. M., was the chief speaker at the exercises held in connection with the opening of the seventh year of the automobile school at the Y. M. C. A. last night. Mr. Reeves' address in part was as follows:

"Ten years ago there were about 3,500 machines in America—now there are 400,000.

"Ten years ago there were 27 factories (200 cars being a record production for any one of them)—now we have almost 100 producing factories, to say nothing of a like number of experimentors, involved in the making of motor cars, while an annual production of 15,000 and even 25,000 cars in one factory is not unusual.

"In a decade the capital of the automobile and accessory makers has increased from approximately $6,200,000 to $450,000,000, of which $275,000,000 is in motor car factories alone.

"Ten years ago the number of persons employed in making automobiles and accessories was estimated at 2,000; now there are 278,000 individuals including those in salesrooms and garages.

"Ten years ago there were probably 800 chauffeurs in New York State, which now boasts of almost 25,000 registered drivers.

"Automobile Row in New York in 1900 showed 14 different makes of cars; now there are 84 for you to select from.

"Ten years ago the average price of cars was $1,100, then it ran up to $2,137 in 1907, after which, with the increase in the number of moderate priced machines, it has come down to $1,545, although the very high-grade cars are selling at even higher prices than they were two years ago.

"When the fundamental patent covering the modern gasoline automobile was issued to George B. Selden in 1895, even the greatest dreamer had no idea of what 1910 would show in the motor car industry, and it has been all the result of work by able men with ideas. Money has had comparatively little to do with it. Although a wealthy man to-day, as a result of his invention, under which 83 manufacturers pay royalties, George B. Selden was a poor man ten years ago. Most of our cars of today came not so much from capital as from brains and mechanical genius in men who began at the bottom of the ladder.

"Great credit for the present position of the motor car industry is due those pioneers like Winton, Ford, Haynes, Apperson, Maxwell, Buick, Olds, Duryea, Packard and a dozen others whose names are now household words.

"At the same time, however, I would not take credit from the business men of the industry who have financed the manufacture and marketed the products. They are a mighty important part of the success, for it was the enterprise, the faith in the industry and the ability to manufacture and market on the part of the captains of industry that supplied the world with the concrete and developed ideas of the engineers and mechanical men.

"The future is your problem, however. Are all the chances gone?

"Will automobiles continue to be used?

"How many people can maintain them?

"Will they take the place of the horse?

"What is the best branch of the industry for me to enter?

"These are among the important questions that confront you gentlemen.

"Perfect as our cars appear, with their silent, powerful motors nd excellent design and construction, the automobile of ten ears hence will show radical changes. The present general deign may continue, but think of the improvements that can be made. Improvements in transmission, in greater simplicity and easier control, in increased power and in economy of fuel consumption, to say nothing of the ever increasing need of something to improve, to cheapen or to supplant the pneumatic tire, which, like the perpetual motion problem, has thus far seemed impossible of solution. It is the general opinion that the pneumatic tire will always be with us except for very heavy vehicles, and while greatly improved in the past few years, it offers a fine opportunity for betterment.

"Now as to the use of motor cars. They are certain to increase in number, solely on account of their utility, without regard to pleasure use. Every farmer needs one, and the Government reports show more than 5,000,000 farms in this country. We know that every doctor must have one and there are 7,700 in New York City alone, and 140,000 in the country.

"Every contractor, every suburban real estate agent, and if the truth be really told, every man, if not an owner now, hopes at some time to operate his own motor car.

"Constantly decreasing maintenance expense is making it possible for more and more people to own machines, even if for pleasure use alone. Moreover, in this great country of ours there are 997,000 families with an annual income of $3,000 or more. It is believed that America will continue to buy annually 200,000 motor cars of all types, approximately that number having been sold during the past twelve months.

"Naturally the greatest field for motors in the future is for the freight carrying vehicle, which offers the solution of those many problems involved in our present wasteful method of transferring merchandise by horse-drawn vehicles.

"Using a motor car which will carry twice the load, at twice the speed, and requiring only half the space, will be like increasing the width of our streets six times. It must always be borne in mind that there are at present 7,000,000 horse-drawn vehicles in use in this country, and an average of 900,000 horse-drawn vehicles being made every year, almost all of which must be supplanted by motor cars.

"The industry, new as it is, requires new men. Some of those in it now have lived on the overflow, simply because no better men were obtainable. Many salesmen in our local trade know little or nothing about the cars they sell. There are scores of chauffeurs in New York who should be in jail instead of driving motor cars. They should bar from driving those men, owners or chauffeurs, who run with mufflers open, that whirl round corners, hog the center of the road, and disregard pedestrians (of whom there are still a few).

"Those makers who turn out badly designed cars, those promoters who would sell you stock in an automobile company on the promise that you will get rich over night are passing and the automobile industry is on a more substantial foundation than ever before.

"The 83 factories in the Association which I have the honor to represent are looking for men of ideas. Opportunities are coming up every day. The reward is not alone money, but a stnading in the business world; a reputation for your friends and family to be proud of, and the always enjoyable sensation of having accomplished something worth while. Energetic and loyal work in the automobile industry assures a future for every man here to-night. The business, with its almost unlimited field, is one of the most substantial in America, and the rantings of dyspeptic pessimists who have viewed its rapid strides with alarm cannot halt its growth in this blessed country where every man has the opportunity to prove his worth and to receive the just reward of his efforts."

Detroit Motor News

STEAM NAVIGATION COMPANY PREPARES TO EMBARK IN TRANSPORTATION THROUGH AIR—OWEN MERGER CONFORMED—FORD TO INVADE NEW YORK

DETROIT, Oct. 24—Anticipating the time when aerial navigation will to some extent supplant the means of travel now in vogue, the Detroit & Cleveland Aerial Navigation Co., of Detroit, has been incorporated, with a nominal capital stock of $50,000. The new organization, which by the way, so far as can be learned, is the first company to be chartered for carrying passengers through the air, is made up of stockholders in the Detroit & Cleveland Navigation Co., and is much more far-reaching than the name would indicate. The company operates side-wheel passenger fleets between Detroit, Cleveland, Buffalo and Mackinac, and it is the intention as soon as aerial navigation has been rendered practical to supplement this service with a full line of airships for the accommodation of those desirous of traveling in that manner.

"We will not do any experimenting," says Vice-President and General Manager A. A. Schantz. "Our business is purely transporting passengers and freight. The minute airships become sufficiently practical we will add service of this nature. The capital stock mentioned in our articles of incorporation is merely nominal, and will be increased when the occasion requires. Personally I believe it will be a long time before any man succeeds in crossing the ocean in an airship of any sort. But with the rapid advancement in the development of aeroplanes there is no reason that I can see why flights of two or three hundred miles should not be common within a few years, at the most. When that time arrives we want to be prepared for it."

Details have been completed for the taking over of the Owen Motor Car Company, of this city, by the Reo Company, of Lansing, as announced in THE AUTOMOBILE. Holders of Owen stock will receive stock in the Reo Company on an equitable basis, and some of the Owen officers will be given executive positions in Lansing. All the equipment and stock in the Detroit plant is being removed to Lansing, and the Reo will be managed on a more comprehensive scale than the rather limited manner in which affairs had been conducted since its organization.

The Ford Motor Company is to invade New York in a manufacturing way, announcement being made of the purchase of a tract of land at Jackson and Honeywell avenues, Long Island City, upon which a four-story concrete structure, 75 x 265 feet will be erected. This building will be equipped with every manufacturing facility, and will be at the disposal of dealers and subdealers in the vicinity of New York who handle Ford cars, and their customers. There will also be a fine display room and convention hall for branch managers of the Atlantic seaboard. It is the intention to have this factory ready for business by the middle of March.

Atlanta Speedway Meet

MORE THAN HALF A HUNDRED CARS ENTERED FOR THE SECOND ANNUAL FALL MEETING—PUTTING THE TRACK IN SHAPE

ATLANTA, GA., Oct. 24—One week from next Thursday afternoon, on the Atlanta Speedway, the second annual fall meeting of the Atlanta Automobile Association will get under way, with fifty or more cars taking part. Ten days before the meet forty-seven were entered and a half dozen promised.

As most of these machines are strictly stock chassis affairs this race meet should be the best stock chassis event ever held here.

The Atlanta association will give away nearly $12,000 to the cars that take part and there should be enough entries in every event to make it exceptionally interesting. The list follows:

Thursday, November 3.—Time trials, free-for-all, 1 mile; 161-230 cubic inches, 12 miles; free-for-all, 20 miles; 231-300, 10 miles; free-for-all, Southern amateur championship, 10 miles; free-for-all, 10 miles; 451-600, 20 miles; Coca Cola trophy, 301-450, 100 miles.

Friday, November 4.—161-230 cubic inches, 10 miles; free-for-all, 10 miles; 231-300 cubic inches, 12 miles; free-for-all, 20 miles; 301-450 cubic inches, 14 miles; amateur free-for-all, 20 miles; free-for-all handicap, 10 miles; City of Atlanta trophy, 451-600 cubic inches, 200 miles.

Saturday, Nov. 5.—Event 18, Australian pursuit race; event 19, amateur free-for-all, 20 miles; event 20, Atlanta Speedway Grand Prize race, free-for-all, 250 miles.

The entries to date include: E-M-F, 2; Fiat "60"; Pope-Hartford, 3; Cole "30," 2; Cole 1911; National "60"; National "40," 2; Falcar, 3; Staver, 3; Knox "60"; Benz "200"; Darracq; Lozier "40"; Westcott; Parry, 2; Firestone-Columbus, 3; Renault; MacFarlan, 2; Halladay; Lozier; Simplex, 2; Marmon, 5; Stearns; Abbott-Detroit, 2; Marquette-Buick.

Ironing out and oiling Atlanta speedway for the fall meeting

Filling the soft spots and making the surface hard and level

Flyers Breaking Records

ENTRANTS AT BELMONT PARK INTERNATIONAL AVIATION TOURNAMENT GIVE EXCELLENT DEMONSTRATION OF AEROPLANES' STATUS

WITHOUT doubt the first international aviation meet on American soil, which is now being held at Belmont Park, L. I., has proved an immense success so far as it has progressed. The tournament opened last Saturday and will continue through next Sunday. Air experts from all the nations that have made considerable progress in the art of flying are present.

Saturday was very cloudy and foggy and the exhibition was not markedly unique save for the atmosphere of mystery that was cast about by the heavy air.

Sunday had been too windy for safe flight, and when the breeze died down to 15 miles an hour and held steady, the crowds poured out to see the flights.

At one time during the hourly distance race, there were ten aeroplanes circling the course.

Some very high speed was made. Aubrun in a Bleriot turned one round of the course at the rate of 62 miles an hour and his performance was equalled by the Antoinette, a giant monoplane, driven by Latham. J. Armstrong Drexel in a Bleriot mounted to the height of 7105 feet.

Tuesday was another favorable day for flying and the spectacle of the preceding day was repeated. On Thursday the flight from the course to and around the Statue of Liberty will be tried, weather permitting.

As a sporting event, one of the Monday races was delightful. Grahame-White in a Farman and Ralph Johnstone in a Wright were leading neck and neck until within two minutes of the conclusion of the hour, with Aubrun and Drexel in Bleriots and Latham in the Antoinette trailing. Suddenly the crowd noticed that the monoplane division was closing on the biplanes and entering the final round, the five flyers were bunched. Flying high, the Antoinette shot ahead, making the last turn with the Farman second and Aubrun's Bleriot, third. It was a finish like that of an automobile cup race or a fierce drive of thoroughbred horses as far as interest was concerned.

The patronage of the tournament has been excellent. Following is a summary of the events:

Saturday

First Hourly Distance: Grahame-White (Farman), 30 m.; 51:44 1-5.
Second Hourly Distance: Grahame-White (Farman), 30 m.; 59:23 1-5.
First Hourly Altitude: Hoxsey (Wright), 742 feet.
Second Hourly Altitude: Hoxsey (Wright), 673 feet.
Totalization of distance: Grahame-White, 2 hours; Moisant, 1:42:10 4-5; Drexel, 19:41 4-5; Hoxsey, 8:05 2-5.
Cross-Country: Moisant, 20 miles, 39:41 4-5.

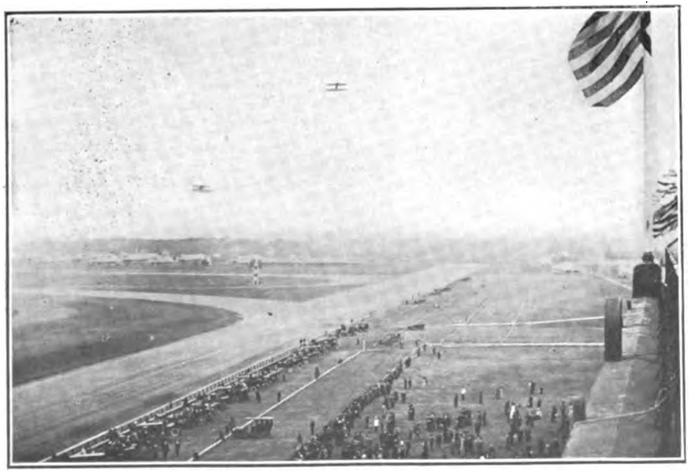
Sunday (weather prevented flights)

Monday

First Hourly Distance: Drexel (Bleriot), 42 miles; 54:33 3-5.
Second Hourly Distance: Latham (Antoinette), 31 1-2, 48:41 4-5.
First Hourly Altitude: Drexel (Bleriot), 5,615 feet.
Second Hourly Altitude: Drexel (Bleriot), 7,105 feet.
Speed Contest: McCurdy (Curtiss), ten laps in 19:49 1-5.
Daily total of duration: Hoxsey, 1:57:13 1-5; Grahame-White, 1:55:17 4-5; Johnstone, 1:49:28 2-5.

Tuesday

First Hourly Distance: Latham, 28 1-2 miles in 54:36 4-5.
Second Hourly Distance: Grahame-White, 21 miles in 34:16 4-5.
First Hourly Altitude: De Lesseps, 6,391 feet.
Second Hourly Altitude: Johnstone, 7,303 feet.
Cross-Country: Radley, 20 miles; 19:48 4-5.
Total of duration: Hoxsey and Johnstone, 2 hours; Latham, 1 hour.



View from Grand Stand at Belmont Park Aviation Meet

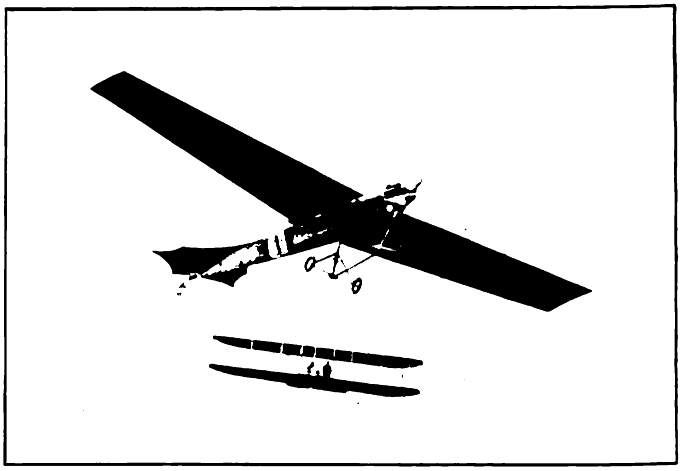
Auto Show Attracts Much Attention

While the aircraft center attention out-doors at the Belmont Park Tournament, the big betting ring under the grandstand is the scene of an attractive display of automobiles and accessories. On the right in coming from the track is the exhibit of the Peerless Motor Car Co. Two handsome limousines are shown. They are of 1911 model and represent in appearance the height of motor luxury.

Next to the Peerless is the exhibit of the Cadillac Motor Car Co. Three 1911 models are shown—a demi-tonneau, touring car and limousine. This exhibit is the most complete and comprehensive at the show and is constantly attended.

The Cole "30" is stationed next in line, showing a close-coupled car and a torpedo speedster. Prominent in this exhibit is the Massapequa Trophy which was won October 1 on the Vanderbilt Cup course by a Cole.

The Mitchell-Lewis Motor Co. shows a Mitchell equipped with a demi-tonneau of graceful lines and business-like appearance.



Latham in Antoinette and Johnson in Wright

Next in line is a Stevens-Duryea limousine.

A Chalmers demi-tonneau completes the show on the west side of the ring.

Across the main aisle is the exhibit of the West Side Y. M. C. A. school. This includes a Lozier engine in operation.

The American Propeller Co., showing a line of aero propellers, is next to the left and then come the booths of the Hartford and Goodyear tire companies, showing aero tires chifly.

The exhibit of Marburg Brothers is popular. The line on show is the Mea magneto, S. R. O. bearings and Duralumin, an alloyed aluminum which has several of the properties of steel and which is said to be important as to the future development of the aeroplane.

The Bosch Magneto has the next booth with its well-known line.

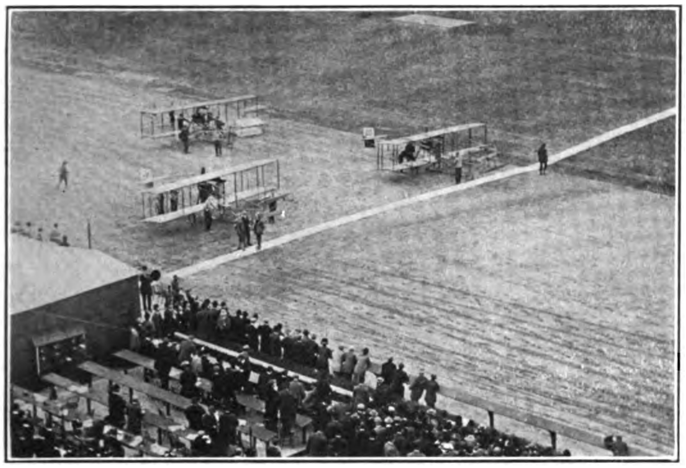
Peter A. Frasse & Co. show steel tubing and cast and turned balls for bearings.

Bliven & Carrington exhibit motor greases, steel bases and the Poldhuite line.

John A. Roebling's Sons Co. shows bare and insulated cables of all sorts, wire cloths, and drop-forged tools.

The Aerial Navigation Company exhibits a line of propellers. The Simms Magneto, Century Rubber, Livingston Radiator, showing radiators, and Booth Demountable Rims, fill up the space to the section devoted to the Aerial Equipment Co., which is showing the Anzani motor.

In the middle of the big inclosure the Metz Co., of Waltham, Mass., has the most prominent station. Two Metz automobiles are shown, a runabout and the other a special delivery package car, equipped with a drum-like receptacle for carrying packages. The cars have two 3.5 bore cylinders. The company also shows a completely equipped monoplane.



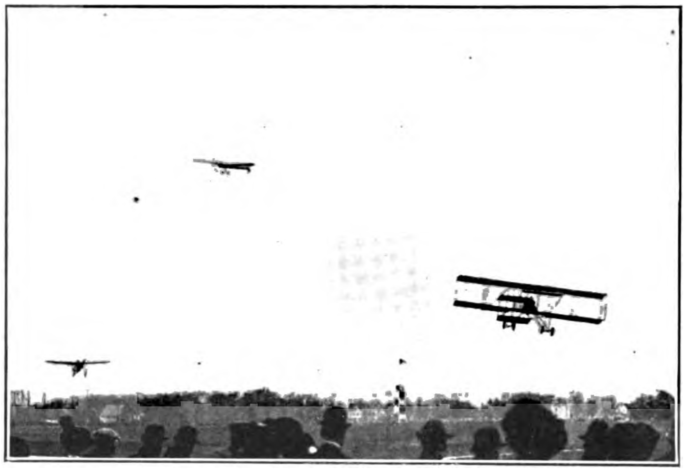
Start of One-hour Flight at Belmont Park Aviation Meet

Alongside the Metz exhibit is that of the "Ever Ready" automatic motor starter. This device is shown in action attached to an automobile. Pressure on a pedal from the driver's seat spins the engine and starts the car. The device is attached at the lower end of the radiator, secured to the crankshaft and supported upon a metal bracket. It appears like an inverted headlight and is cased in brass. The device is composed of two springs which are wound up in the first place by hand, but after the first winding, the motor itself takes care of that part of its operation. The springs are released by a trigger that is worked by the pedal. The starter is shown by the Auto Improvement Co.

The Stewart Automobile Academy completes the list of exhibitors.

Aeroplane Stresses Not Yet to Be Calculated

In view of recent fatalities and near-fatalities as well as the unimpressive ending of the aeroplane race from Chicago to New York, a technical contemporary has issued a warning to airmen coupled with the advice to go about the construction of aeroplanes armed with a full complement of stress sheets, and the daily press, in some instances, speeds the advice as sound and needful. The stress calculations used for bridge construction should be taken as a model, according to this advice, and it is the opinion of the esteemed contemporaries that many fatal accidents of the air will be averted if the advice is followed. By inference it is suggested that improved stability and equilibrium, greater reliabilty of motor power and increased efficiency in the application of power against the atmosphere are less urgently needed than stress sheets. In this connection it may be worth remembering that the load and wind stresses in bridges are calculated with a view to a very large factor of safety in the actual construction, that they relate to materials of well-established properties, that neither rapid motion nor elastic reaction nor violent shocks affecting the whole structure as a unit are of primary interest in bridges and that, despite all these elements in favor of stress calculation as against empiric data, bridges are not infrequently found to be deficient, as witness the accident to the Quebec bridge during its construction and the reinforcements which it was deemed necessary to incorporate in the Blackwell Island bridge connecting New York city with Brooklyn. Some comical incidents of the automobile industry also throw light on the subject. A prominent Belgian engineer, quite scientific, conceived the idea that stress sheets were the first requirements for making an automobile "stand up" in the days when automobiles generally didn't. The car he produced weighed about seven times as much as other cars and, while hard to move with much speed, managed to pound itself to pieces. A scientist of New York city started on the same lines, but before he and his staff were through calculating the empiric world had produced a car that was good enough for him. Even to-day many of the formulas employed for calculating dimensions for automobile parts have at some point in the chain of mathematics upon which they are founded a factor representing average dimensions of the corresponding part in a number of different and reputable automobiles, and this factor, almost needless to say, is essentially empiric as well as empirically essential. To find a substitute for this factor in the construction of aeroplanes would at the present moment be impossible for want of suitable examples for imitation The aeroplane constructor will have to do as the automobile constructor did; that is, devise a use of materials for which there is no exactly parallel precedent, while applying as best he may those after all not very complicated laws of mechanics upon which all stress calculations will be based, as soon as a sufficient mass of data shall have been gathered.



Grahame-White in foreground and the Antoinette highest in the air

A really fundamental difficulty about the working out and applying of stress sheets lies furthermore in the very contrary, almost cantankerous fact that the stresses to which an aeroplane is subject in flight depend wholly upon the action of air against surfaces, and the action of air against surfaces constitutes in itself the whole question of aeroplane construction. If it were understood well enough for admitting the calculation of stresses, such knowledge would be applied first of all to the improvement of the surfaces by which stress is brought to bear against the air for the purposes of sustentation; it would be applied for the improvement of the propeller by which stress is brought to bear against the atmosphere for purposes of propulsion, and it would be applied to all the neutral parts in order to reduce the stress of the air resistance which they encounter.

Boston Trucks in Contest

THIRTY-FIVE COMMERCIAL GASOLINE VEHICLES TAKE PART IN ROAD RUN FROM BOSTON—120 MILES UNDER SERVICE CONDITIONS

BOSTON, Oct. 22—After two days of running, covering a distance of approximately 120 miles, the different trucks entered in the Boston *American's* contest reached the Back Bay late this afternoon and were checked in. It proved quite a success, all things considered. The caravan of trucks and official cars that made the trip from Boston to Newburyport and return numbered about 50 and as the machines passed through the different cities they attracted a lot of attention.

The first day's run was 58 miles to Newburyport by way of Lowell and Haverhill. At these places checking stations were established and this allowed the trucks to be inspected. It was the same story on the return trip of 62 miles through Gloucester, Salem, Lynn, etc.

The trucks were divided into five classes according to their capacity and a sixth division was added for private owners. All the classes filled pretty well considering that it was not a club affair. The machines were started off from Boston by Mayor Fitzgerald at nine Friday morning with the heavy trucks getting the right of way. They were allowed a speed of six miles an hour. The others were given varying time limits according to loads and capacity. On the return it was found that the big trucks did so well that a speed of eight miles an hour might be made without trouble and so this was ordered. It was an instructive object lesson in commercial vehicle transportation to watch the machines touring along carrying loads of furniture, wire, coal, lumber, flour and a lot of other such stuff on the long hauls.

One of the gasoline stations in Boston commercial run

Many of the Boston dealers took a hand in it to help make the run a success by doing the official work and loaning cars to convey interested persons.

One of the most notable features of the test was the few accidents to the trucks entered in the run. In each instance where accidents happened there was not an occasion when the trucks meeting with mishaps could have been found at fault in any way. The first truck in trouble was a five-ton Reliance which when entering Billerica, on the first day's run, skidded while passing through a bed of soft sand and was ditched. The truck was disabled to an extent that the repairs necessary to continue could not have been made.

The Johnson truck was next to meet with an accident which was brought about by the slippery street car rails on which the truck skidded and smashed into a telegraph pole. The force of the impact was so great that both of the front wheels of the truck were demolished.

The final awards will not be made until the cost of operation has been computed. Following is the record of the test:

CLASS A

3 Hart Kraft, clean.
11 Warren Detroit, clean.
18 Metz, 10 points.
19 Metz, 38 points.
20 Metz, withdrawn.
44 Reliance, 164 points.
47 I. H. C., clean.

CLASS B

4 Atterbury, clean.
5 Gramme, withdrawn.
2 Rapid, clean.
8 Rapid, clean.
9 McIntyre, clean.
10 McIntyre, withdrawn.
13 Franklin, clean.
23 Victor, clean.
30 Randolph, withdrawn.
21 Wilcox, clean.

CLASS C

28 Garford, clean.
29 Garford, clean.
30 Alco, clean.
34 Frayer-Miller, 6 points.

CLASS D

6 Knox, clean.
32 Frayer-Miller, clean.
33 Frayer-Miller, clean.
35 Johnson, clean.
36 Johnson, withdrawn.

CLASS E

24 Sampson, clean.
26 Morgan, clean.
48 Reliance, withdrawn.

PRIVATE OWNERS

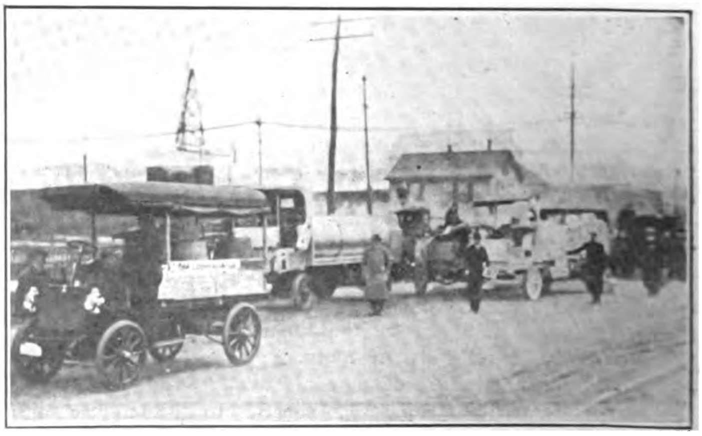
17 Rapid, clean.
1 Autocar, clean.
40 Gramme, clean.
41 Autocar, clean.
43 Frayer-Miller, clean.
49 Mack, clean.

Many Penalties in Washington Reliability

WASHINGTON, D. C., Oct. 25—At the end of the fourth day of the Washington *Post* run from Washington to Richmond and return the score stood as follows: No. 5 Washington, clean; No. 11 Parry, 1 point; No. 6 Washington, 2 points; No. 9 Maxwell, 3 points; No. 8 Maxwell, 8 points; No. 14 Buick, 9 points; No. 7 Columbia, 22 points; No. 3 Buick, 64 points, and No. 12 Washington, 928 points. The most serious accident of the first day was sustained by Griffin Halstead's Washington car. While negotiating a rough piece of road near Purcellville the car dropped into a hole, breaking the front axle. He telephoned to Washington for a new axle and expects to check out in the morning. Arrison's Washington car was close behind Halstead and in endeavoring to avoid hitting it, Arrison stalled his motor, and suffered a loss of one point. Mortimer's Buick "10" had trouble with a loose oil sight feed and lost five points, while the Buick "Bug" lost one point for similar trouble.

Upon arrival at Washington it was announced that there were no remaining clean scores.

A Buick "17," with Willis Cronkite at the wheel, is acting as pilot car, while a Washington, driven by H. F. Baughmann, serves as the referee's car.



Contestants lining up at a control

Twenty-one Enter Grand Prize

LIST, NOT YET COMPLETE, IS IMPRESSIVE, AND EXPERT SAYS AMERICAN ROAD RECORD WILL BE BROKEN IN

SAVANNAH, Oct. 24—The course over which the Grand Prize race for the international trophy of the Automobile Club of America will be run November 12 will be 17.2 miles long. This shortening of the route was effected by cutting off the Thunderbolt Road protuberance, thus leaving the course in the shape of a rough quadrilateral, with two stretches of practically straight, flat, superlatively smooth roadway, five and eight miles in length. Massage work on the course is being prosecuted by 250 men and already it appears to be in almost perfect condition, some of the cracks who have been over it recently predicting a general shattering of records next month.

The actual list of paid-up entrants includes two Marquette-Buicks, two Marmons, three Fiats, three Benz cars, one Roebling-Planche. two Loziers, the double Vanderbilt Cup winner, the black Alco, three Nationals, Simplex, two Lorraine-De Dietrichs, and a Renault.

To date the entry list for the two light car events to be run off November 11 includes three Falcars, one Marmon, one Marquette-Buick, three Maxwells, two Coles, two Abbott-Detroits and two Cartercars.

In writing exclusively to THE AUTOMOBILE, C. A. Emise, of the Lozier Co., says:

"I went over the course yesterday with Mulford and he did not hesitate to say that it was the best ever laid out on American soil. He expressed the opinion that the American road racing record would be broken and that the possibility existed that the world's mark would be set at a new level. Our car can average better than 70 miles an hour on this course and if that is good enough to win, we will be there or thereabouts.

"There are only three turns that have to be taken at less than 50 miles an hour and the surface is lightning fast throughout. The Ferguson avenue boulevard, some seven miles straightaway, will give an opportunity for the big racing machines to let themselves out to the extreme limit of motor car speed.

"Mulford figures that if the Lozier can do in excess of 70 miles an hour the special racing machines ought to do better. if they stand up. He looks for some of the rounds to be made at the rate of 90 miles an hour.

"In 1908 the course was practically new and, as every one who was here remembers, the surface was perfect. Since then two years have elapsed and the roads have had a chance to settle. The traffic has never been heavy and when the racers start the course will be marvelously fast.

"The Savannah Automobile Club is taking hold of the work of preparation with its accustomed vim and energy."

Group of officials at a checking station—Boston truck run

Entries Stream in for "American's" Truck Test

Following is the list of entries in the New York *American's* Commercial vehicle contest, to be run next Friday and Saturday:

Entrant	Truck ..	Capacity, lbs.
GASOLINE TRUCKS. Div. 1—1,000 lbs. and less		
Hart-Kraft Motor Co	Hart-Kraft	1,000
Veerac Sales Co	Veerac	1,000
Chase Motor Truck Co	Chase	1,000
Hadfield Company	Hatfield	1,000
Hadfield Company	Hatfield	1,000
John Moore & Co	Brush	600
John Moore & Co	Brush	600
Division 2—1,001 to 3,000 lbs.		
Victor Motor Truck Co	Victor	3,000
Ladue Carmer Co	Atterbury	3,000
John Wanamaker	Autocar	2,000
Commercial Maintenance Co	Grabowsky	2,000
Motor Car Maintenance Co	Grabowsky	2,000
Grabowsky Power Wagon Co	Grabowsky	2,000
Torbensen Motor Car Co	Torbensen	2,000
Cass Motor Truck Co	Cass	2,000
Flanagan Motor Car Co	Monitor	2,000
Alden Sampson Mfg. Co	Alden Sampson	1,500
Chase Motor Truck Co	Chase	1,500

Johnson clean score truck, No. 35, in Boston commercial run

Entrant	Truck	Capacity, lbs.
Division 3—3,001 to 5,000 lbs.		
Walter Auto Truck Mfg. Co	Walter	4,000
Kelly Motor Truck Co	Kelly	5,000
Renault Frères Selling Branch	Renault	3,500
Division 4—5,001 to 8,000 lbs.		
Schleicher Motor Vehicle Co	Schleicher	6,000
Knox Automobile Co	Knox	8,000
Alden Sampson Mfg. Co	Alden Sampson	8,000
W. A. Wood Auto Mfg. Co	Commer Car	8,000
Standard Gas & Electric Power Co	Standard	8,000
Carlson Motor & Truck Co	Carlson	6,000
General Acoustic Co	British Atlas	6,000
Kelly Motor Truck Co	Kelly	7,000
Motor Car Maintenance Co	Grabowsky	6,000
American Locomotive Co	Alco	6,000
Walter Auto Truck Mfg. Co	Walter	6,000
Division 5—10,000 lb. and Over		
Metzger Motor Car Co	Hewitt	20,000
Benz Auto Import Co	Gaggenau	14,000
R. L. Morgan Co	Morgan	10,000
Alden Sampson Mfg. Co	Alden Sampson	10,000
ELECTRIC TRUCKS		
Abraham & Straus	Lansden	2,000
General Electric Co	General Vehicle Co.	2,000
General Vehicle Co	General Vehicle Co.	3,000
P. Daussa & Co	General Vehicle Co.	6,000
General Vehicle Co	General Vehicle Co.	1,000
General Vehicle Co	General Vehicle Co.	2,000
General Vehicle Co	General Vehicle Co.	4,000
General Vehicle Co	General Vehicle Co.	7,000
General Vehicle Co	General Vehicle Co.	10,000
The Lansden Co	Lansden	3,000
The Lansden Co	Lansden	3,000
R. H. Macy & Co	Lansden	2,000
John Wanamaker	Commer Car	2,000
Edison Co. of Brooklyn	General Vehicle Co.	10,000
Central Brewing Co	General Vehicle Co.	10,000
Central Brewing Co	General Vehicle Co.	6,000
Borden Condensed Milk Co	General Vehicle Co.	7,000
Alex D. Shaw	General Vehicle Co.	7,000
Apmann & Meyer	General Vehicle Co.	2,000
Edison Brooklyn Co	Auto Maintenance Co.	3,000

Automobile Notes at Hoosier Capital

INDIANAPOLIS, IND., Oct. 24—The Circuit Court has held invalid the ordinance requiring all drivers of automobiles and riders of motorcycles to register with the Board of Public Safety and pay a license fee of $1. There have been 4,224 licenses issued under the ordinance, and it is improbable the fees collected will be returned as they were not paid under protest. Objection was raised to the ordinance because it required no qualifications to obtain license, yet left it to the discretion of the board to issue or decline to issue licenses. Objection was also raised to the feature permitting the police judge to revoke licenses for violation of any automobile law or ordinance.

About 200 automobiles were in the industrial parade given by the Indianapolis Trade Association last Tuesday night, eighty-eight of the number being automobile trucks carrying special exhibits of manufacturers and wholesalers of the city. The exhibits of the automobile concerns were elaborate, many having 1911 models in line. The Willys-Overland Company had a special display representing the evolution of transportation. This consisted of an Indian drag, a horse-drawn vehicle and an automobile. The Waverley company, among other things, displayed a coupè on a brilliantly illuminated and beautifully decorated electric truck. The parade was seven miles long, 179 business concerns participating.

The Cole Motor Car Company has recently increased its capital and will build approximately 2,000 cars next season.

Two New Michigan Companies Formed

DETROIT, Oct. 24.—From Lansing comes the announcement of the formation there of a million dollar company which will manufacture motor trucks designed under the direction of R. E. Olds, president of the Reo Motor Car Company.

The Brady-Nagel Manufacturing Company has been organized here, and is negotiating with several concerns making automobile parts and doing special machine work, with a view to consolidating them into one big organization. James J. Brady, formerly vice-president and superintendent of the Chalmers Motor Company, is president of the new concern; William J. Nagel, formerly deputy city controller, is secretary and treasurer, and George Henderson, formerly assistant superintendent of the Chalmers plant, is superintendent.

Richmond Auto Club Elects Officers

RICHMOND, VA., Oct. 24.—The Richmond Automobile Club at a recent meeting elected officers as follows: Horace S. Hawes, president; E. C. Pelouze, vice-president; Melville C. Peck, secretary and treasurer. Preston Belvin, W. B. Nelson, Dr. M. D. Hodge, Jr., John B. Swartout and Rufus C. Williams, executive committee.

Six new members were elected: Dr. A. G. Franklin, Dr. H. B. Sanford, Dr. Charles R. Robins, Joseph Sorg, H. W. Rountree and John C. Easley.

Short News of Interest

—W. J. Connell, Boston representative of the Wheeler and Schebler carbureter factory, of Indianapolis, has changed his location to 555 Boylston street.

—The Halladay Motor Car Company, of 1224 South Olive street, Los Angeles, Cal., has just been organized to handle Halladay cars in California.

—The Heaney Automobile Company, of Minneapolis, Minn., northwestern distributors of Halladay cars, have just completed an additional two-story building.

—The Superior Motor Sales Company has been incorporated in St. Louis for $75,000, to effect a reorganization of the recently established business of M. M. Baker & Company, 2007 Locust street.

—Stephen Holt has been appointed Eastern selling representative of the Abbott Motor Company, of Detroit, and will have New York, Pennsylvania, New Jersey and Maryland, with headquarters at Philadelphia.

—Announcement is made of the increase in capital stock of the Phoenix Auto Supply Company, of St. Louis, from $12,000 to $50,000, fully paid. The assets of the company are scheduled at $105,421, the liabilities $44,365.

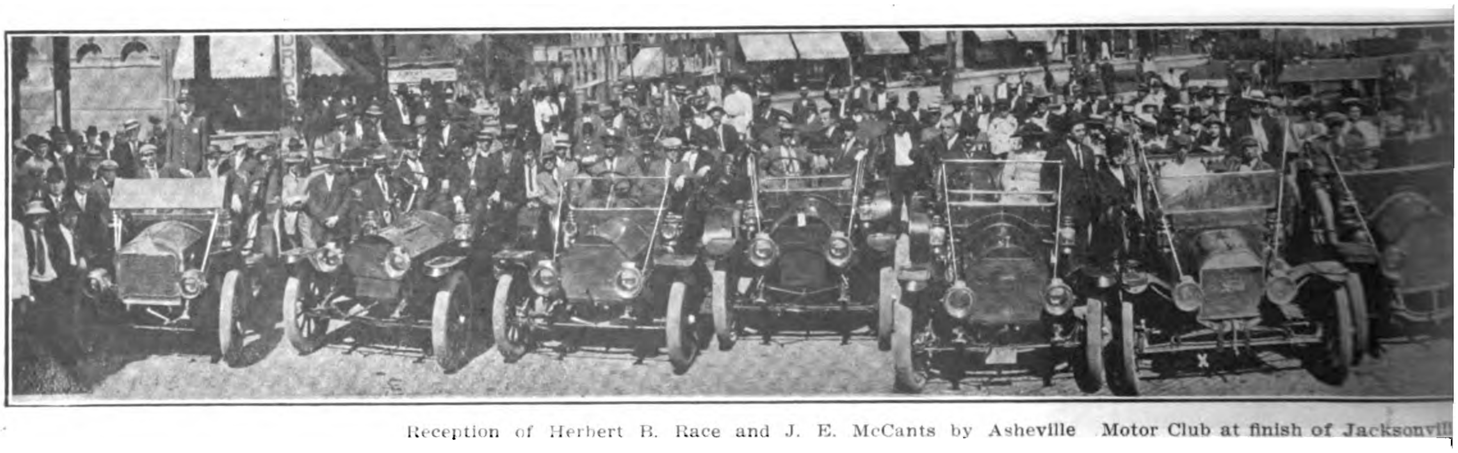
—W. H. Marble, formerly connected with the purchasing department of the Chalmers Motor Company and the Pullman Motor Car Company, has joined the sales force of the Abbott-Detroit Motor Company in the Middle West.

—Berne Nadall, member of the contest board (technical committee) of the A. A. A. and also one of the original Chicago Motor Club (technical committee), has joined forces with the Rayfield carbureter, as special factory representative.

—J. S. Bradfield, for eight years connected with New York and Boston newspapers, is now a member of the salesforce of the Cole "30" in Boston. He was one of the first men in Boston to get the taxi service started through consultations with Police Commissioner O'Meara.

—The Stephenson Motor Car Company, of Milwaukee, Wis., builder of the Utility truck, has opened its new plant at South Milwaukee, which was leased for one year with a three-year option in addition. The plant, formerly occupied by a wrench and tool concern, has been entirely remodeled and a new equipment installed. Thirty to forty men are now being employed. Two types are built, a one-ton car at $2,000 and a three-ton truck at $3,500. George L. Stephenson is president of the company.

—While the principal object of the newly formed Western Automobile Association is to get a broad and speedy highway built between British Columbia and the Northern border of Mexi-



Reception of Herbert B. Race and J. E. McCants by Asheville Motor Club at finish of Jacksonvill

IEF ITEMS CULLED HERE AND THERE FOR ICK READING—INTERESTING ALIKE TO MAKER D USER

co, it will first take up the improvement of roads in the West, particularly the road between Portland and Seattle. With good roads the trip between Seattle and Portland would be an ideal twelve hours' drive.

—The usual Fall shifts are taking place in Atlanta's automobile colony. The Henderson Motor Co. of Atlanta has opened headquarters to sell Cole and Westcott cars. F. J. Long, formerly of the Olds-Oakland Co., has taken charge as manager. The Warren Motor Car Co. has had a representative in Atlanta looking for some man to take charge of a local agency. The Stearns Co. has opened a local branch with John Toole in charge.
